  5. Adults with compensated cirrhosis and low levels of viremia (<2000 IU/ml) should be treated with entecavir or tenofovir disoproxil to reduce the risk of decompensation, regardless of ALT level.

DISPOSITION

- Follow-up as outpatient
- Acute disease: Infection will resolve (defined as clearance of hepatitis B surface antigen within 6 mo) in 90% of adult patients
- Rare fatalities (fulminant hepatitis)
- Possible chronic carrier state, cirrhosis, hepatocellular carcinoma
- Cure of HBV is an unrealistic goal for most patients with chronic infection since only a few patients will become HBsAb with current treatment modalities

REFERRAL

To infectious disease specialist and gastroenterologist for consultation regarding fulminant hepatitis or prolonged cholestasis, for cases of uncertain etiology, or for treatment of CAH

PEARLS & CONSIDERATIONS

COMMENTS

- Virus and HBsAg in high titers in blood for 1 to 7 wk before jaundice and for a variable time thereafter.
- Screening (HBV surface antigen [HBsAg], HBV core antigen antibody, antibody to HBsAg) should be offered to high-risk groups.
- Transmission is possible during entire period of HBsAg (and especially during HBeAg) in serum.
- Universal precautions should be followed for all contacts with blood or secretions/excretions contaminated with blood.
- Antiviral therapy is recommended in pregnancy to reduce perinatal transmission if HBsAg positive and HBV DNA >200,000 IU/ml. Can use tenofovir disoproxil, lamivudine, or telbivudine. Tenofovir may be preferred because it has a better resistance profile and there are more safety data in pregnany women with hepatitis B. Fig. 3 describes an algorithm for the treatment of hepatitis B surface antigen (HBsAg)-positive mothers during pregnancy.
- Preventing before exposure:
  1. Lifestyle changes.
  2. Meticulous testing of blood supply (although some chronically infected, infectious donors are HBsAg negative).
  3. Sterilization via steam or hypochlorite.
  4. Hepatitis B vaccine for high-risk groups given IM in deltoid to induce HBsAb (response should be confirmed) is protective (>90% effective). The FDA has recently approved a two-dose hepatitis B virus vaccine (HEPLISAV-B) for use in adults ≥18 yr old, administered at 0 and 1 mo.
  5. Recommendation for universal childhood immunization with doses at birth, 1 mo, and 6 mo.

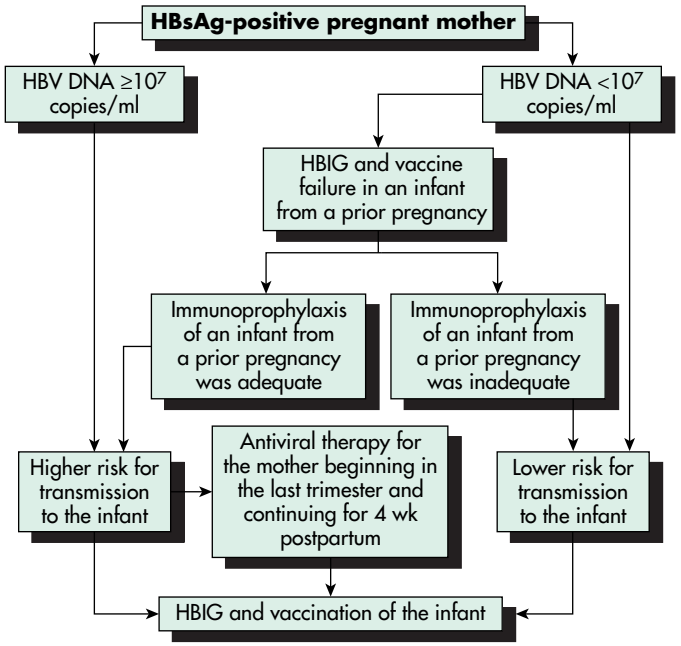

FIG. 3 Algorithm for the treatment of hepatitis B surface antigen (HBsAg)-positive mothers during pregnancy. The goal of treatment in highly viremic mothers is to lower the serum HBV DNA level by several $\log_{10}$ IU/ml by the time of delivery to minimize the chance of newborn infection. The choice of antiviral agent is less important if treatment of the mother is not needed long term. In the event that the treatment needs to be continued after delivery, the patient should be started on a high-genetic-barrier drug initially or switched to one immediately after delivery. See text for further details about drug selection. *HBIG,* hepatitis B immune globulin; *HBV,* hepatitis B virus. (From Feldman M et al. [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, WB Saunders.)

- Prevention after exposure:
  1. HBV hyperimmune globulin (HBIG) (0.06 ml/kg IM) given immediately after needlestick, within 14 days of sexual exposure, or at birth, followed by HBV vaccination. A second dose of HBIG is given in 28 days for those refusing vaccine or vaccine nonresponders.
  2. Standard immune globulin: Nearly as effective as HBIG.
- Preventive therapy with entecavir or tenofovir disoproxil for patients who test positive for HBsAg and are undergoing chemotherapy may reduce the risk for HBV reactivation and HBV-associated morbidity and mortality.
- Hepatitis B prophylaxis is described in Section V.
- Table 3 summarizes interpretation of serologic markers and serum DNA in hepatitis B.

BASIC INFORMATION

DEFINITION

Hepatitis C is an acute liver parenchymal infection caused by hepatitis C virus (HCV).

SYNONYM

Transfusion-related non-A, non-B hepatitis (incubation period averages 6 wk, intermediate between hepatitis A and B)

ICD-10CM CODES

B17.1	Acute hepatitis C
B18.2	Chronic viral hepatitis C
B17.10	Acute hepatitis C without hepatic coma
B17.11	Acute hepatitis C with hepatic coma
B19.20	Unspecified viral hepatitis C without hepatic coma
B19.21	Unspecified viral hepatitis C with hepatic coma

EPIDEMIOLOGY & DEMOGRAPHICS

Hepatitis C infection is the most common chronic blood-borne infection in the United States. About 3% of baby boomers test positive for the virus. The CDC now recommends testing for hepatitis C for anyone born from 1945 to 1965.

INCIDENCE: HCV infects more than 185 million individuals worldwide. Approximately 20% of patients chronically infected with HCV progress to cirrhosis.

- 150,000 new cases/yr (37,500 symptomatic; 93,000 later chronic liver disease; 30,700 cirrhosis). The incidence of acute HCV has declined substantially over the past 30 yr (from 7.4/100,000 to 0.7/100,000).
- ~9000 of these ultimately die of HCV infection; most common (40%) cause of nonalcoholic liver disease in the United States

PREVALENCE (IN U.S.):

- Overall prevalence of anti-HCV antibody is 1% to 1.2% (an estimated 2.7 million persons nationwide).
- Highest prevalence in hemophiliacs transfused before 1987 and users of injection drugs, 72% to 90%. Over past 30 yr, blood transfusion as a risk factor declined from 15% of cases to 1.9%.
- Among low-risk groups, prevalence 0.6%.

PREDOMINANT SEX: Slight male predominance.

PREDOMINANT AGE: Highest prevalence in 30- to 49-yr age group (65%).

PEAK INCIDENCE:

- 20 to 39 yr of age.
- African Americans and whites have similar incidence of acute disease; Hispanics have higher rates.
- Prevalence is substantially higher among non-Hispanic blacks than among non-Hispanic whites.

GENETICS: Neonatal infection is rare; increased risk with maternal HIV-1 coinfection.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms usually develop 7 to 8 wk after infection (range of 2 to 26 wk), but 70% to 80% of cases are subclinical.
- 10% to 20% report acute illness with jaundice and nonspecific symptoms (abdominal pain, anorexia, malaise).
- Fulminant hepatitis may rarely occur during this period.
- After acute infection, 15% to 25% have complete resolution (absence of HCV RNA in serum, normal ALT).
- Progression to chronic infection is common, 50% to 84%. 74% to 86% have persistent viremia; spontaneous clearance of viremia in chronic infection is rare. 60% to 70% of patients will have persistent or fluctuating ALT levels; 30% to 40% with chronic infection have normal ALT levels.
- 15% to 20% of those with chronic HCV will develop cirrhosis over a period of 20 to 30 yr; in most others, chronic infection leads to hepatitis and varying degrees of fibrosis. Table 1 summarizes factors associated with progression of hepatic fibrosis in patients with chronic HCV infection. Table 2 describes factors associated with cirrhosis in persons with hepatitis C infection.
- 0.4% to 2.5% of patients with chronic infection develop hepatocellular carcinoma (HCC).
- 25% of patients with chronic infection continue to have an asymptomatic course with normal LFTs and benign histology.
- In chronic HCV infection, extrahepatic sequelae include a variety of immunologic and lymphoproliferative disorders (e.g., cryoglobulinemia, membranoproliferative glomerulonephritis, and possibly Sjögren syndrome, autoimmune thyroiditis, polyarteritis nodosa, aplastic anemia, lichen planus, porphyria cutanea tarda, B-cell lymphoma, others).
- Fig. 1 illustrates the natural history of HCV infection.

ETIOLOGY

- Caused by HCV (single-stranded RNA flavivirus). HCV genotype 1 accounts for about 75% of HCV in the US. Genotypes 2 and 3 account for about 20-25% of infections, genotype 4 for 6%, and genotypes 5 and 6 for about 1%.
- Most HCV transmission is parenteral.
- In the United States, advances in screening of blood and blood products have made transfusion-related HCV infection rare (the risk is estimated to be 0.001% per unit transfused).
- Injecting-drug use accounts for most HCV transmission in the United States (60% of newly acquired cases, 20% to 50% of chronically infected persons).
- Occupational needlestick exposure from an HCV-positive source has a seroconversion rate of 1.8% (range 0% to 7%).
- Nosocomial transmission rates (from surgery and procedures such as colonoscopy and hemodialysis) are extremely low.
- Sexual transmission and maternal-fetal transmission are infrequent (estimated at 5%).
- No identifiable risk in 40% to 50% of community-acquired hepatitis C, but snorting of cocaine by shared use of straw or rolled-up paper has been identified as a risk factor because it causes microscopic bleeding of nasal mucosa.
- HCV infection may stimulate production of cytotoxic T lymphocytes and cytokines (INF-γ), which probably mediate hepatic necrosis.

TABLE 1 Factors Associated With Progression of Hepatic Fibrosis in Patients With Chronic Hepatitis C Virus Infection

Established	Possible	Not Associated
Age >40 yr	Increased hepatic iron concentration	Viral genotype
Alcohol consumption	Male gender	Viral load
Hepatitis B virus coinfection	Serum ALT level	
HIV coinfection		
Immunosuppressed state		
Insulin resistance		
Marijuana use		
Obesity		
Schistosomiasis		
Severe hepatic necroinflammation		
Smoking		
White race		

ALT, Alanine aminotransferease; *HIV,* human immunodeficiency virus.
From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Saunders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other hepatitis viruses (A, B, D, E).
- Other viral illnesses producing systemic disease (e.g., yellow fever, EBV, CMV, HIV, rubella, rubeola, coxsackie B, adenovirus, HSV, HZV).
- Nonviral hepatitis (e.g., leptospirosis, toxoplasmosis, alcoholic hepatitis, drug-induced hepatitis [acetaminophen, INH], toxic hepatitis).

WORKUP

- Acute hepatitis C antibody, viral genotyping, viral titers.
- LFTs; CBC.

NOTE: ALT is an easy and inexpensive test to monitor infection and efficacy of therapy. However, ALT levels may fluctuate or even be

TABLE 2 Factors Associated With Cirrhosis in Persons With Hepatitis C Infection

Factor	Impact	Comment
Environmental		
Alcohol use	+4	The importance of minimal alcohol ingestion (<20 g/day) has not been established
Host		
HIV infection	+4	Increasingly important as HIV-related survival improves; may be masked by competing mortality
HBV infection	+3	Strong effect when HBsAg positive; relatively uncommon
Age	+4	Strong effect; increases as low as 40 yr. Hard to distinguish from infection duration
Body mass index	+2	Associated with metabolic syndrome
Duration of HCV infection	+3	Cirrhosis is rare before 10 yr
HLA type	+1?	HLA B54 is correlated with increased risk of cirrhosis; DRB1*0301 with lack of cirrhosis
Viral		
Quasispecies complexity	+1	Cross-sectional studies cannot assess causality, and complexity may be confounded by duration of infection
HCV genotype 1	+1?	Genotype 1b in some, but not other studies, could be confounded by longer duration of 1b infections
Quantitative measures of viremia (serum or plasma HCV RNA level)	+2	Not always detected or lost in multivariate analysis of age or HIV

HCV, Hepatitis C virus; *HIV,* human immunodeficiency virus; *HLA,* human leukocyte antigen; *RNA,* ribonucleic acid.

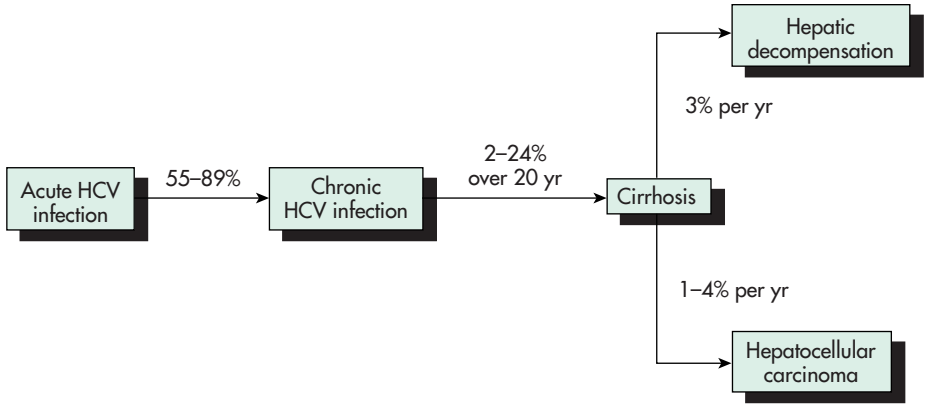

FIG. 1 Natural history of HCV infection. Hepatic decompensation includes ascites, hepatic encephalopathy, variceal hemorrhage, hepatorenal syndrome, or hepatic synthetic dysfunction. *HCV,* Hepatitis C virus. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.)

normal in active or chronic infection and even with cirrhosis, and ALT may remain elevated even after clearance of viremia.

- Liver biopsy with histologic staging had been the gold standard for assessing the degree of disease activity and the likelihood of disease progression, and also to help rule out other causes of liver disease.
- Transient elastography (FibroScan) is a non-invasive specialized ultrasound assessment that quantifies liver fibrosis and corresponds it to the equivalent in the METAVIR scoring system traditionally used in liver biopsies. It is being increasingly used in place of liver biopsy in many institutions.

LABORATORY TESTS

- Diagnosis is often by exclusion, because it takes 6 wk to 12 mo to develop anti-HCV antibody (70% positive by 6 wk, 90% positive by 6 mo).
- Diagnostic tests include serologic assays for antibodies and molecular tests for viral particles.
  1. Enzyme immunoassay is the test for anti-HCV antibody:
     a. The current version can detect antibody within 4 to 10 wk after infection.
     b. False-negative rate in low-risk populations is 0.5% to 1%.
     c. False negatives also occur in immune-compromised persons, HIV-1, renal failure, HCV-associated essential mixed cryoglobulinemia.
     d. False positives in autoimmune hepatitis, paraproteinemia, and persons with no risk factors.
- The recombinant immunoblot assay that was previously recommended as a follow-up to positive antibody test is no longer available. The CDC now recommends that anyone who tests positive for HCV antibodies receive a follow-up HCV RNA test.
- Qualitative and quantitative HCV RNA tests using PCR: Lower limit of detection is <43 IU/ml.
- Used to confirm viremia and to assess response to treatment.
- Qualitative polymerase chain reaction (PCR) useful in patients with negative enzyme immunoassay in whom infection is suspected.
- Quantitative tests use either branched-chain DNA or reverse transcription PCR; the latter is more sensitive.
- Viral genotyping can distinguish among genotypes 1, 2, 3, 4, 5, and 6, which is helpful in choosing therapy; most of these tests use PCR. Genotypes 1, 2, 3, and 4 predominate in the United States and Europe (genotype 1 is especially common in North America [60% to 75% of Hep C infections in the United States]).
- FibroSure score uses a combination of six serum markers of liver function plus age and gender in a patented algorithm to generate a measure of fibrosis and necroinflammatory activity in the liver as a quantitative surrogate marker for the corresponding METAVIR scoring system.
- LFTs: ALT and AST may be elevated to more than eight times normal in acute infection; in chronic infection ALT may be normal or fluctuate.
- Bilirubin may be five to 10 times normal.
- Albumin and prothrombin time generally normal; if abnormal, may be harbinger of impending hepatic necrosis.
- WBC and erythrocyte sedimentation rate (ESR) are generally normal.

- HIV testing. Infection with HCV is seen in 15% to 30% of individuals with HIV infection due to shared risk factors.
- All patients infected with HCV should be tested for Hepatitis B. HBV vaccination is recommended for susceptible individuals, because HBV reactivation may occur during treatment of HCV with direct-acting antiviral therapy.

IMAGING STUDIES

- Transient elastography (FibroScan) to quantify liver fibrosis as an absolute score. Some insurance companies use this score as a basis to determine eligibility for treatment.
- Sonogram: Rapid liver size reduction during fulminant hepatitis or mass in HCC.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Activity and diet as tolerated; avoid saw palmetto and green tea leaf herbs.

ACUTE GENERAL Rx

- Supportive care.
- Avoid hepatically metabolized drugs.

CHRONIC Rx

Response to therapy is influenced by HCV genotype. Recommendations for the treatment of hepatitis C in adults are changing constantly as new therapies come to the market. The advent of direct-acting antiviral agents (DAAs) has drastically changed treatment options and improved cure rates to greater than 95%. The most up-to-date guidance is available at the website www.hcvguidelines.org. The following is a brief summary of the guidelines based on genotype. Newer agents containing fixed-dose combinations of direct-acting antiviral (DAA) drugs have been approved for HCV infections caused by any of the six major HCV genotypes in patients without cirrhosis or with compensated cirrhosis. These agents are Mavyret (combination of glecaprevir, an HCV NS3/4A protease inhibitor, and pibrentasvir, an NS5A inhibitor) and Vosevi (combination of the NS5B nucleotide polymerase inhibitor sofosbuvir, the NS5A inhibitor velpatasvir, and the NS3/4A protease inhibitor voxilaprevir). Both agents are approved for use in treatment-experienced patients and Mavyret is also approved for treatment-naïve patients. Currently, these treatment regimens are extremely expensive.

Genotype 1a: Options for treatment-naïve patients without cirrhosis, listed by level of evidence:

- Daily fixed-dose combination of elbasvir (50 mg)/grazoprevir (100 mg) (Zepatier) for 12 wk and in those who do not have baseline NS5A RAVs (amino acid substitutions at 28, 30, 31, or 93 that confer resistance to elbasvir). Rating: Class I, Level A.
- Daily fixed-dose combination of glecaprevir (300 mg)/pibrentasvir (120 mg) (Mavyret) for 8 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of ledipasvir (90 mg)/sofosbuvir (400 mg) (Harvoni) for 12 wk. Rating: Class I, Level A. (Can also use this regimen for only 8 wk for patients who are non-black, HIV-uninfected, and whose HCV RNA level is <6 million IU/ml. Rating: Class I, Level B.)
- Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg) (Epclusa) for 12 wk. Rating: Class I, Level A.
- Alternative regimens:
  1. Daily fixed-dose combination of paritaprevir (150 mg)/ritonavir (100 mg)/ombitasvir (25 mg) with dasabuvir (600 mg) as part of an extended-release regimen or plus twice-daily dosed dasabuvir (250 mg) with weight-based ribavirin for 12 wk. Rating: Class I, Level A.
  2. Daily simeprevir (150 mg) plus sofosbuvir (400 mg) for 12 wk. Rating: Class I, Level A.
  3. Daily daclatasvir (60 mg) plus sofosbuvir (400 mg) daily for 12 wk. Rating: Class I, Level B.
  4. Daily fixed-dose combination of elbasvir (50 mg)/grazoprevir (100 mg) (Zepatier) with weight-based ribavirin for patients with baseline NS5A RADs for elbasvir for 16 wk. Rating; Class IIa, Level B.

Genotype 1a: Options for treatment-naïve patients with compensated cirrhosis:

- Daily fixed-dose combination of elbasvir (50 mg)/grazoprevir (100 mg) [Zepatier] and in those in whom no baseline NS5A RAVs for elbasvir are detected for 12 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of glecaprevir (300 mg)/pibrentasvir (120 mg) [Mavyret] for 12 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of ledipasvir (90 mg)/sofosbuvir (400 mg) [Harvoni] for 12 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg) [Epclusa] for 12 wk. Rating: Class I, Level A.
- Alternative regimen:
  1. Daily fixed-dose combination of elbasvir (50 mg)/grazoprevir (100 mg) [Zepatier] with weight-based ribavirin for 16 wk for patients who have baseline NS5A RASs. Rating: Class IIa, Level B.

Genotype 1b: Treatment-naïve patients without cirrhosis:

- Daily fixed-dose combination of elbasvir (50 mg)/grazoprevir (100 mg) [Zepatier] for 12 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of glecaprevir (300 mg)/pibrentasvir (120 mg) [Mavyret] for 8 wk. Rating: Class I, A.
- Daily fixed-dose combination of ledipasvir (90 mg)/sofosbuvir (400 mg) [Harvoni] for 12 wk. Rating: Class I, Level A. (Can treat for 8 wk in patients who are non-black, HIV-uninfected, and whose HCV RNA level is <6 million IU/ml. Class I, Level B.)
- Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg) [Epclusa] for 12 wk. Rating: Class I, Level A.
- Alternative regimens:
  1. Daily fixed-dose combination of paritaprevir (150 mg)/ritonavir (100 mg)/ombitasvir (25 mg) with dasabuvir (600 mg) as part of an extended-release regimen or plus twice-daily dosed dasabuvir (250 mg) for 12 wk. Rating: Class I, Level A.
  2. Daily simeprevir (150 mg) plus sofosbuvir (400 mg) daily for 12 wk. Rating: Class I, Level A.
  3. Daily daclatasvir (60 mg) plus sofosbuvir (400 mg) for 12 wk. Rating: Class I, Level B.

Genotype 1b: Treatment-naïve patients with compensated cirrhosis:

- Daily fixed-dose combination of elbasvir (50 mg)/grazoprevir (100 mg) [Zepatier] for 12 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of glecaprevir (300 mg)/pibrentasvir (120 mg) [Mavyret] for 12 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of ledipasvir (90 mg)/sofosbuvir [Harvoni] for 12 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg) [Epclusa] for 12 wk. Rating: Class I, Level A.
- Alternative regimens:
  1. Daily fixed-dose combination of paritaprevir (150 mg)/ritonavir (100 mg)/ombitasvir (25 mg) with dasabuvir (600 mg) as part of an extended-release regimen or plus twice-daily dosed dasabuvir (250 mg) with weight-based ribavirin for 12 wk Rating: Class I, Level A.

Genotype 2: Treatment-naïve regimens without cirrhosis:

- Daily fixed-dose combination of glecaprevir (300 mg)/pibrentasvir (120 mg) [Mavyret] for 8 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg) [Epclusa] for 12 wk. Rating: Class I, Level A.
- Alternative regimen: Daily daclatasvir (60 mg) plus sofosbuvir (400 mg) for 12 wk. Rating: Class IIa, Level B.

Genotype 2: Treatment-naïve patients with compensated cirrhosis:

- Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg) [Epclusa] for 12 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of glecaprevir (300 mg)/pibrentasvir (120 mg) for 12 wk. Rating: Class I, Level B.
- Alternative regimen: Daily daclatasvir (60 mg) plus sofosbuvir (400 mg) for 16 to 24 wk. Rating: Class IIa, Level B.

Genotype 3: Treatment-naïve patients without cirrhosis:

- Daily fixed-dose of glecaprevir (300 mg)/pibrentasvir (120 mg) for 8 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg) [Epclusa] for 12 wk. Rating: Class I, Level A.
- Alternative regimen: Daily daclatasvir (60 mg) plus sofosbuvir (400 mg) for 12 wk. Rating: Class I, Level A.

Genotype 3: Treatment-naïve patients with compensated cirrhosis:

- Daily fixed-dose combination of glecaprevir (300 mg)/pibrentasvir (120 mg) [Mavyret] for 12 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg) [Epclusa] for 12 wk. Rating: Class I, Level A.
- Alternative regimens:
  1. Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg)/voxilaprevir (100 mg) [Vosevi] when Y93H amino acid substitution is present for 12 wk. Rating: IIa, Level B.
  2. Daily daclatasvir (60 mg) plus sofosbuvir (400 mg) with or without weight-based ribavirin for 24 wk. Rating: Class IIa, Level B.

Genotype 4: Treatment-naïve patients without cirrhosis:

- Daily fixed-dose combination of glecaprevir (300 mg)/pibrentasvir (120 mg) {Mavyret] for 8 wk. Rating: Class I Level A.
- Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg) [Epclusa] for 12 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of elbasvir (50 mg)/grazoprevir (100 mg) [Zepatier] for 12 wk. Rating: Class IIa, Level B.
- Daily fixed-dose combination of ledipasvir (90 mg)/sofosbuvir (400 mg) [Harvoni] for 12 wk. Rating: Class IIa, Level B.
- Alternative regimen: Daily fixed-dose combination of paritaprevir (150 mg)/ritonavir (100 mg)/ombitasvir (25 mg) and weight-based ribavirin for 12 wk. Rating: Class I, Level A.

Genotype 4**:** Treatment-naïve patients with compensated cirrhosis:

- Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg) [Epclusa] for 12 wk. Rating: Class I, Level A.
- Daily fixed-dose combination of glecaprevir (300 mg)/pibrentasvir (120 mg) [Mavyret] for 12 wk. Rating: Class I, Level B.
- Daily fixed-dose combination of elbasvir (50 mg)/grazoprevir (100 mg) [Zepatier] for 12 wk. Rating: Class IIa, Level B.
- Daily fixed-dose combination of ledipasvir (90 mg)/sofosbuvir (400 mg) [Harvoni] for 12 wk. Rating: Class IIa, Level B.
- Alternative regimen: Daily fixed-dose combination of paritaprevir (150 mg)/ritonavir (100 mg)/ombitasvir (25 mg) and weight-based ribavirin for 12 wk. Rating: Class I, Level A.

Genotypes 5 and 6: Treatment-naïve patients with and without cirrhosis:

- Daily fixed-dose combination of glecaprevir (300 mg)/pibrentasvir (120 mg) for 8 wk with no cirrhosis. Rating: Class I, Level A and 12 wk with compensated cirrhosis. Rating: Class I, Level A.
- Daily fixed-dose combination of sofosbuvir (400 mg)/velpatasvir (100 mg) [Epclusa] for 12 wk. Rating: Class I, Level B.
- Daily fixed-dose combination of ledipasvir (90 mg)/sofosbuvir (400 mg) [Harvoni] for 12 wk. Rating: Class IIa, Level B.

Drug interactions can be significant with these regimens (http://www.hepdruginteractions.org). With DAA regimens, viral loads are measured at 4 wk into the therapy to monitor success and at the end of therapy. A final viral load is measured 12 wk after completing the treatment, and if undetectable, the patient is considered to have a sustained virologic response (SVR), which equates to a cure.

For *treatment-experienced* patients there are guidelines per genotype as well (www.hcvguidelines.org). Treatment is based on genotype and whether the patient is without cirrhosis or with compensated cirrhosis. Regimen will depend on whether the patient had been exposed in the past to interferon/ribavirin-based regimens, NS3 protease inhibitors regimens (telaprevir, boceprevir, simeprevir), or DAA agents.

In 2017, a new salvage regimen was approved: Once-daily Vosevi (fixed-dose combination of 100 mg voxilaprevir (HCV NS3/4A protease inhibitor) plus 400 mg sofosbuvir and 100 mg velpatasvir. Eligible patients include:

- Genotypes 1, 2, 3, 4, 5, or 6 in patients previously treated with a regimen containing an NS5A inhibitor for 12 wk (NOTE: In clinical trials, prior experience with NS5A inhibitors included daclatasvir, elbasvir, ledipasvir, ombitasvir, or velpatasvir)
- Genotype 1a or 3 in patients previously treated with sofosbuvir without an NS5A inhibitor for 12 wk. (NOTE: In clinical trials, prior treatment experience included sofosbuvir with or without any of the following: Peginterferon alfa/ribavirin, ribavirin, HCV NS3/4A protease inhibitors: Boceprevir, simeprevir, or telaprevir.)
- Liver transplantation:
  1. Hepatitis C is the main indication for liver transplantation in the United States.
  2. It is the only option for patients with deteriorating HCV-related cirrhosis and for some patients with HCC.
  3. Recurrent infection occurs in almost all patients with progressive fibrosis and cirrhosis; as many as 20% progress to cirrhosis within 5 yr posttransplant.

DISPOSITION

- The absence of HCV RNA in blood 12 wk after completion of treatment is considered a cure. There is no need to check HCV antibodies since they will remain positive indefinitely.
- SVR after treatment among HCV-infected persons at any stage of fibrosis is associated with reduced HCC.
- Periodic abdominal ultrasonography for HCC screening.
- Recent guidelines recommend against measurement of alpha-fetoprotein (AFP) to screen for HCC in patients with chronic hepatitis C due to lack of sensitivity, specificity, and predictive values.

REFERRAL

- To a hepatologist or infectious disease specialist for treatment for hepatitis C in patients who have been previously treated or for treatment failures with DAA agents.
- To a transplant surgeon for consideration of liver transplant if indicated.

PEARLS & CONSIDERATIONS

- More rapid progression of disease in persons who drink alcohol regularly, persons of advanced age at time of infection, and those coinfected with other viruses (HIV, hepatitis B). All persons with identified HCV infection should receive a brief alcohol screening and intervention as clinically indicated.
- Regression of cirrhosis has been demonstrated after antiviral therapy in some patients with chronic hepatitis C. Regression is associated with decreased disease-related morbidity and improved survival.
- The presence of interleukin (IL)-28B and HLA class II is independently associated with spontaneous resolution of HCV infection, and single nucleotide polymorphism IL-28B and DQB1*03:01 may explain approximately 15% of spontaneous resolution of HCV infection.

BASIC INFORMATION

DEFINITION

- A defective RNA virus
- Depends on hepatitis B virus (HBV) for its active viral replication
- Most severe form of viral hepatitis
- Results in severe liver disease often causing cirrhosis and liver failure

SYNONYMS

HDV
Delta virus
Delta agent

ICD-10CM CODES

B16.0 Acute hepatitis B with delta-agent with hepatic coma
B16.1 Acute hepatitis B with delta-agent without hepatic coma
B18. 0 Chronic viral hepatitis B with delta-agent

EPIDEMIOLOGY & DEMOGRAPHICS

- The least common cause of chronic viral hepatitis worldwide.
- Endemic in the Mediterranean Basin and Pacific Islands.
- The rates of occurrence in the tropical and subtropical areas were higher compared with those in northern Europe or North America due to the increased HBV in those locations.
- Immigration from endemic areas to northern Europe and the U.S. has increased HDV in these areas (Fig. E1).

INCIDENCE:

- Increasing in developed countries due to immigration and higher rates of HBV.
- Remains a major health concern in developing countries.

PEAK INCIDENCE: Peak incidence was in the 1980s.

PREVALENCE:

- 15 to 20 million people affected worldwide.
- The highest prevalence is in the Middle East, Central Africa, northern parts of South America, and the Mediterranean basin (Fig. E2).

PREDOMINANT SEX AND AGE:

- Occurs in both sexes
- Age varies
- Historically, the disease is most severe in children and drug addicts, who are often co-infected with hepatitis C or HIV

GENETICS:

- There are eight identified genotypes of HDV.
- The genotype has no influence on management.
- It is unclear whether the genotypes carry substantial clinical or prognostic significance.
- Genotype does have an important role when studying epidemiology.
- Different HBV genotypes may interact with different genotypes of HDV.
- Table E1 illustrates the individual genotypes, their geographical distribution, and the few associated clinical observations.

RISK FACTORS

- Transmitted by parenteral routes.
- Shares the same risk factors as HBV.
- Highest rates of infection are in intravenous drug users.
- Sexual transmission through heterosexual contact can occur.
- Its spread among men who have sex with men has not been evident.
- Vertical transmission can also occur but is rare.
- Box E1 describes persons who should be clinically suspected of having HDV infection.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical manifestations can vary. Because of the obligate relationship of HDV to HBV infection, the natural history of HDV infection depends on the clinical course of HBV. Two distinct types of HDV infections are possible: *Primary infection* (or coinfection), in which infection of HBV and HDV occur simultaneously, and *superinfection*, in which HDV infection is superimposed on established chronic HBV infection. These two different disease states can usually be distinguished by serologic and genomic testing for both viruses (Fig. E3).
- Symptoms can include nausea, lethargy, and abdominal pain.
- The presentation depends on whether it occurs as a coinfection with HBV or as a superinfection in a chronic HBV carrier.
- HBV/HDV coinfection is usually a self-limited acute hepatitis.
- Superinfection can cause a severe acute hepatitis with a drastic clinical course.
- Severe infection can result in liver cirrhosis, liver cancer, liver failure, and even death.
- Coinfection with HBV, HCV, and HIV has increased risk of liver cirrhosis.

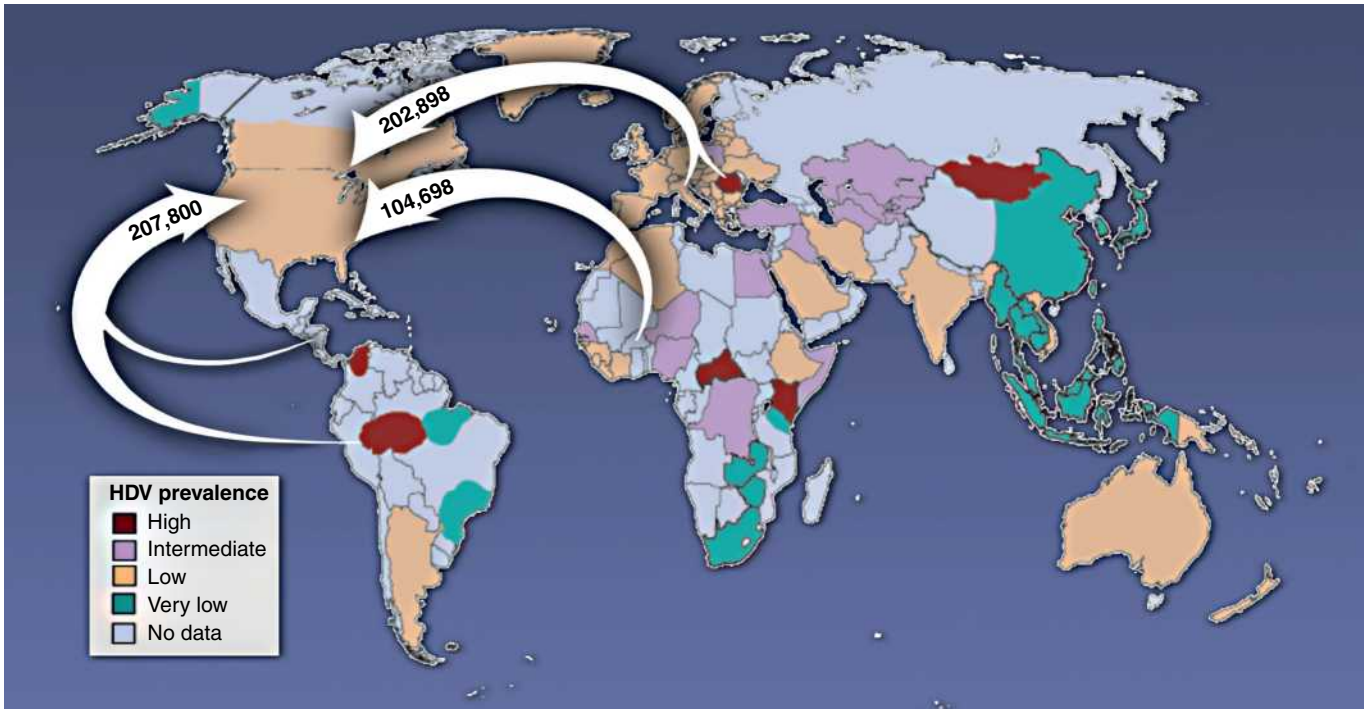

FIG. E1 Worldwide prevalence of hepatitis D virus (HDV) infection and immigration patterns to the U.S. from endemic regions of the world (1974 to 2008). The numbers within the *arrows* indicate the total number of hepatitis B surface antigen-positive immigrants who are estimated to have come to the U.S. from various regions during this period. Changing immigration patterns are likely to account for a greater prevalence of HDV infection in the U.S. than previously considered. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, WB Saunders.)

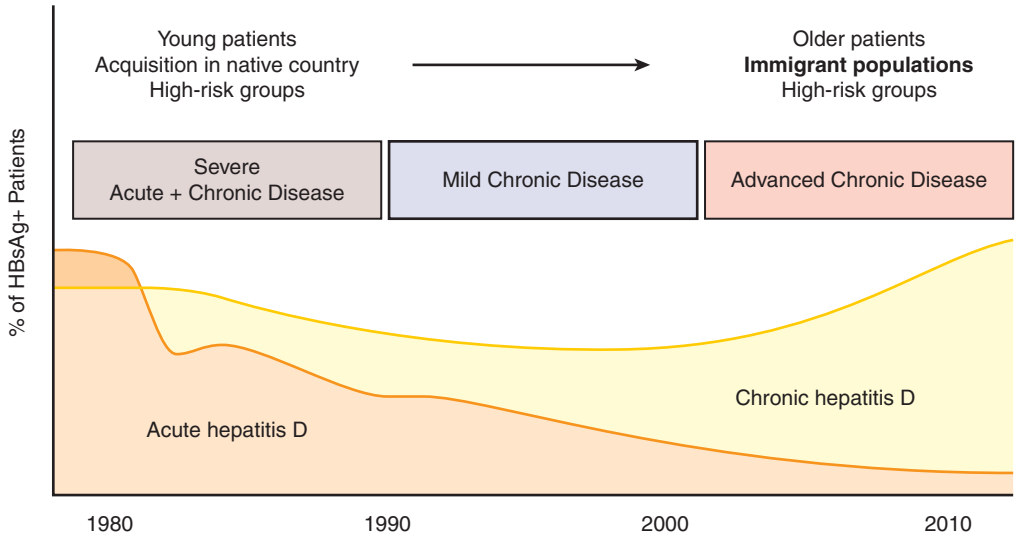

FIG. E2 Timeline of the changing epidemiology of hepatitis D virus (HDV) infection since the late 1970s. HDV had a dramatic, acute appearance in the early to mid-1980s, and many of the patients were young, from countries with a high prevalence of HDV infection, or identified as being in high-risk groups (e.g., people who inject drugs). Since that time, many of the patients with severe liver injury have died because of the infection, and many of those with initially mild hepatitis have developed advanced liver disease and its complications. With changing immigration patterns in Europe and the U.S. (see Fig. E1), more cases of chronic HDV infection are being seen in persons who have relocated from high-prevalence areas. *HBsAg,* Hepatitis B surface antigen. (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, WB Saunders.)

TABLE E1 Hepatitis D Virus Genotypes

Genotype	Geography	Clinical Observations
1 (Most common)	North America, Europe, Middle East, North Africa, Mediterranean, and Taiwan	Lower remission rates and more adverse events compared to genotype 2 in Taiwan
2	North and East Asia	Milder disease (in East Asia)
3	South America (Northern)	Fulminant hepatitis
4	Japan and Taiwan	Milder disease (in East Asia)
5-8	West and Central Africa	N/A

N/A, Not applicable.

BOX E1 Persons Who Should Be Clinically Suspected of Having Hepatitis D Virus Infection*

HBsAg-positive immigrants from regions that are moderately to highly endemic for HDV
HBsAg carriers with a history of injection drug use
Persons with chronic hepatitis B and rapid evolution to cirrhosis or hepatocellular carcinoma
HBsAg carriers who are persistently HBV DNA negative but have active liver disease
Persons with an unexplained acute flare of chronic hepatitis B that is not due to acute hepatitis A or C or reactivation of hepatitis B

*Initial screening with anti-HDV is recommended.
Anti-HDV, Antibody to HDV; *DNA,* deoxyribonucleic acid; *HBsAg,* hepatitis B surface antigen; *HDV,* hepatitis D virus.* From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, WB Saunders.

ETIOLOGY

- HDV requires the hepatitis B surface antigen (HBsAg) for hepatocyte adherence and virion assembly.
- HBsAg carriers serve as the main reservoirs for hepatitis D infection and often become chronic carriers of the virus.
- At least 5% of HBV carriers worldwide are infected with HDV.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

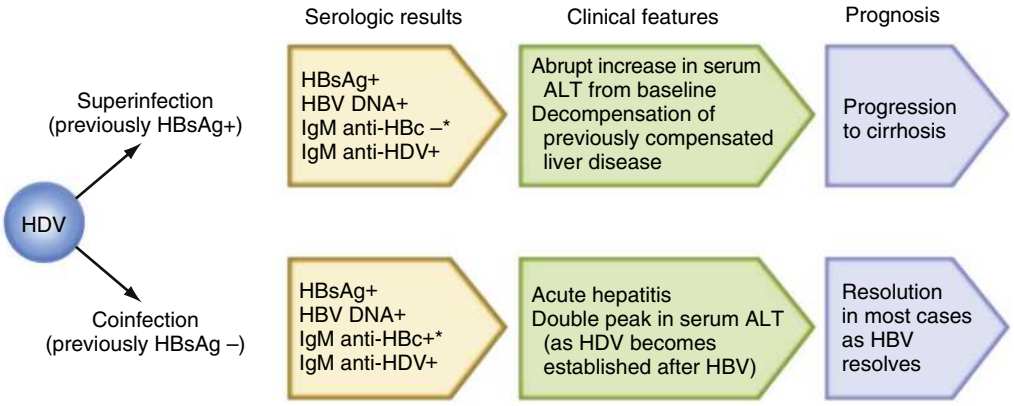
- Acute hepatitis B infection
- Recrudescence of HBV infection in a known HBV carrier

WORKUP

- The first step is to measure the immunoglobulin (Ig) G antibodies to HDV, also known as anti-HD.
- Antibody response may be diminished in immunocompromised individuals, such as those with HIV.
- The most sensitive and specific test is the HDV-RNA measured by polymerase chain reaction (PCR).
- Level of viremia does not correlate with the severity of disease.
- There are no distinct histological characteristics from biopsy when compared to findings from isolated HBV infection.

LABORATORY TESTS

- Patients with coinfection can experience a biphasic course with two peaks of alanine aminotransferase (ALT) elevations several wk apart.
- The first peak occurs during HBV replication, and the second peak occurs during delayed HDV replication.
- Key serological markers in acute co-infection include HDV-RNA, HBV-DNA, HBsAg, immunoglobulin (Ig) M antibody to hepatitis B core antigen (HBcAb), and IgM anti-HDV.
- HDV-RNA and HBV-DNA titers decrease as the infection resolves.
- Hepatitis B surface antibody (HbSAb) is formed as HBsAg disappears.
- IgM anti-HDV can persist even after HbSAb appears and aminotransferases normalize.
- Superinfection with HDV is differentiated from an acute HBV flare by detecting the presence of HDV-RNA and IgM anti-HDV along with measuring HBV-DNA titers, which are elevated in acute HBV infection.



*Distinguishing feature between superinfection and coinfection.

FIG. E3 Serologic results, clinical features, and prognosis of hepatitis D virus *(HDV)* superinfection and coinfection with HDV and hepatitis B virus *(HBV). ALT*, Alanine aminotransferase; *anti-HBc*, antibody to hepatitis B core antigen; *anti-HDV*, antibody to hepatitis D virus; *DNA*, deoxyribonucleic acid; *HBsAg*, hepatitis B surface antigen; *HBV*, hepatitis B virus; *HDV*, hepatitis D virus; *IgM*, immunoglobulin M. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.)

FIG. (From Boyer TD et al: *Zakim & Boyer's hepatology: a textbook of liver disease*, ed 6, Philadelphia, 2012, WB Saunders.)

TABLE 2 Diagnostic Markers for Hepatitis D Virus Infection, Their Importance, and Potential Weaknesses

Diagnostic Markers and Their Importance	Potential Weaknesses
IgG anti-HDV	
Positive in all persons exposed to HDV; persists long term, even after viral clearance May indicate active or past infection; not a neutralizing antibody	May not be elevated in immunocompromised persons.
IgM anti-HDV	
Positive in acute infection; negative in past infection May be used as a surrogate marker for HDV replication Decrease in titers and subsequent clearance in chronic HDV infection is a predictor of spontaneous or therapy-induced remission	Often persists in chronic infection, particularly with active liver disease. Neither 100% sensitive nor specific for HDV replication.
HDAg	
Can be demonstrated in hepatocytes by immunohistochemical staining	The reliability of immunochemistry decreases as the disease becomes chronic. The presence of high titers of neutralizing antibodies (anti-HDV) interferes with detection of HDAg. Less sensitive than molecular assays.
HDV RNA (qualitative)	
Marker of HDV replication Positive in all patients with chronic HDV infection Negative in spontaneous or treatment-induced viral clearance	Variability in the HDV genome and assay primers influences the sensitivity of HDV RNA detection. No WHO standardized assay.
HDV RNA (quantitative)	
Used to measure the level of HDV RNA in serum Useful method for predicting and monitoring treatment response	HDV RNA may be present at a lower titer than the limit of detection (as low as 10 copies/ml). Levels do not reflect the grade or stage of liver disease. May be useful for monitoring patients during therapy with interferon, but there is no WHO standardized assay. Results may differ significantly among laboratories.
HBsAg (quantitative)	
May be useful for predicting or monitoring treatment response during therapy with interferon, because a falling titer heralds HBsAg loss and hence HDV RNA clearance	Confined to research laboratories in the U.S. but commercially licensed in Asia and Europe.

anti-HDV, Antibody to hepatitis D virus; *HBsAg,* hepatitis B surface antigen; *HDAg,* hepatitis D antigen; *HDV,* hepatitis D virus; *Ig,* immunoglobulin; *RNA,* ribonucleic acid; *WHO,* World Health Organization.

From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, WB Saunders.

- The lack of IgM to HBcAb also suggests superinfection in a chronic HBV carrier, rather than acute HBV infection.
- See Fig. E4, *A* and *B*, which illustrate the natural course in coinfection and superinfection, respectively. Table 2 describes diagnostic markers for HDV infection, their importance, and potential weaknesses.

IMAGING STUDIES

Imaging studies are not used in diagnosis.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Supportive care
- Management of symptoms

ACUTE GENERAL TREATMENT

- No current FDA-approved therapy
- Interferon-alpha is the only therapeutic option, which has shown minimal benefit. (Cure rates 25% to 45%). Treatment is indicated in infected patients with progressive liver disease.
- Antivirals against HBV that do not affect HbSAg do not treat HDV.

CHRONIC TREATMENT

- Interferon-alpha should be continued for at least 12 mo.
- Response is determined by the loss of HBsAg.
- Response is often delayed.
- Treatment should be given for at least 1 yr before the individual is determined to be a nonresponder.
- Longer-term therapy is associated with a sustained disappearance of HDV-RNA and HBsAg along with regression of liver fibrosis.
- Relapse after interferon therapy completion is common.
- Investigations of other therapies, such as prenylation inhibitors, are currently ongoing.

DISPOSITION

- HBV/HDV coinfection is usually a self-limited illness that resolves after a few wk.
- 2% of patients with coinfection progress to chronic HDV infection.
- Superinfection can cause a severe acute hepatitis sometimes leading to cirrhosis, liver failure, and death, but usually results in chronic infection.

REFERRAL

Patients should be referred to a hepatologist or someone who is experienced in treating liver disease.

PEARLS & CONSIDERATIONS

COMMENTS

- Consider HDV infection in patients with underlying HBV and progressive liver disease.
- Superinfection can lead to cirrhosis, liver failure, and death.
- Interferon-alpha is the only current therapeutic option, but has severe limitations secondary to side effects and significant relapse rates after treatment completion.

PREVENTION

- Aimed at modifying risk factors.
- No vaccine available for HDV.
- Vaccinating against HBV helps prevent HDV.
- High-risk populations, such as intravenous drug users, should be vaccinated against HBV.

RELATED CONTENT

Hepatitis B (Related Key Topic)

AUTHOR: **Hiresh D. Trivedi, MD**

Hepatitis E

BASIC INFORMATION

DEFINITION

Hepatitis E is an RNA virus transmitted mostly by the fecal-oral route that is among the most frequent causes of acute hepatitis worldwide, with an estimated 20 million cases annually and 70,000 deaths.

SYNONYMS

Previously known as enterically transmitted non-A non-B hepatitis
HEV
Hepatitis E virus
Epidemic non-A, non-B hepatitis

ICD-10CM CODE
B17.2 Acute hepatitis E

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Considered hyperendemic in India, Bangladesh, China, and Mexico (Fig. E1). It is probably the most common cause of acute hepatitis and jaundice in the world.
- In developed nations usually associated with travelers returning from endemic countries (Table E1).
- Large outbreaks can occur and are associated with fecal-contaminated water.
- Person-to-person transmission is thought not to contribute to morbidity in epidemics.

PEAK INCIDENCE:

- Some waterborne outbreaks are more common in summer months.
- Foodborne transmission through raw or undercooked meat of wild deer, boar and domestic pigs, and probably rabbit contributes to cases of hepatitis E in developed nations.

PREVALENCE:

- In endemic countries, HEV prevalence of 25% for all non-A and non-B acute hepatitis cases.
- In endemic countries among blood donors, IgG antibodies are found in as high as 45% of donors.
- In developing countries, prevalence of IgG antibodies is 1% to 4% among blood donors.

PREDOMINANT SEX AND AGE:

- High attack rates are found in adults 15 to 40 yr of age. In developed countries HEV is more common in males over the age of 40.
- Fulminant hepatic failure occurs more frequently during pregnancy, with mortality rates of 15% to 25%.
- Vertical transmission commonly occurs via intrauterine and perinatal routes and can lead to severe liver disease and high mortality in fetuses and neonates.
- Men are more frequently affected than women.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- After an incubation period of 15 to 60 days, most cases are self-limited and asymptomatic (80%). Clinical features of acute hepatitis E are summarized in Box E1.
- Symptomatic patients will experience nonspecific findings:
  1. Flulike myalgia, arthralgia, anorexia
  2. Hepatomegaly, fever, weakness, vomiting, diarrhea
  3. Jaundice, pale stools, darkened urine can also occur, as in other hepatitis infections
- Elevated liver function tests: Total bilirubin, ALT, AST occur 1 to 6 wk after onset of illness.
- Case fatality rate is very low: 0.5% to 4%, except in pregnancy: 15% to 25%.
- Rare complications include pancreatitis, encephalitis, proximal myopathy.

ETIOLOGY

- HEV is the sole member of the *Orthohepevirus* genus of the Hepeviridae family.
- HEV is an icosahedral, nonenveloped, single-stranded RNA virus about 27 to 34 nm in diameter.
- There are four genotypes, of which humans are the host for all four genotypes, and swine and other mammals may also be the hosts for genotypes 3 and 4. Box E2 summarizes features of HEV genotypes 1 and 2. Table E2 compares epidemiologic and clinical features associated with HEV genotypes 1 and 3.

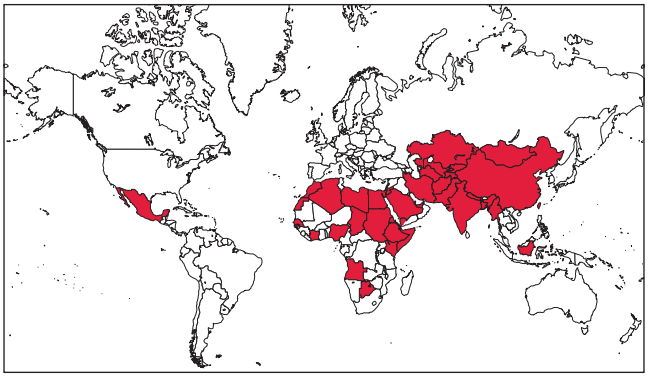


FIG. E1 Geographic distribution of areas where infection with HEV genotypes 1 and 2 is highly endemic *(red areas).* (From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.)

TABLE E1 HEV Genotypes and Their Geographic Distribution

Genotype	Human Cases	Animal Cases
1	South, Southeast and Central Asia, Africa	—
2	Mexico, Western Africa	—
3	U.S., South America, Europe (France, Spain, U.K., the Netherlands), Japan	U.S., China, Japan, Southeast Asia, Australia, New Zealand, South America
4	China, Taiwan, Japan, Vietnam	India, China, Taiwan, Japan

From Feldman M et al. (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Hepatitis A: Another fecal-oral hepatitis virus with low mortality and low chronic state rate
- Hepatitis B, hepatitis C, hepatitis D
- Drug-induced liver injury such as from isoniazid
- Dengue fever, malaria
- Typhoid fever

WORKUP

- Consists of tests on blood and feces on a clinical-compatible patient/travel to endemic areas.
- Patients will shed detectable virus in stool 1 wk prior to start of illness and persist for up to 2 wk afterward.
- Diagnosis is made by detection of HEV IgM or RNA.

LABORATORY TESTS

- Anti-HEV IgM antibodies can be detected 4 days after onset of jaundice and persist for 5 mo.
- Anti-HEV IgG antibodies are detectable shortly after appearance of the IgM antibodies.
- PCR on blood and feces.
- Fig. E2 illustrates the typical course of HEV infection.

PATHOLOGY

- On liver biopsy will demonstrate a cholestatic picture and classic types of acute viral hepatitis.
- In fulminant cases, there is massive hepatic necrosis.

TREATMENT

- Treatment is supportive, as most cases are self-limited in normal hosts.
- Solid-organ transplant patients benefit from ribavirin treatment with chronic hepatitis E (70% response rate).

BOX E1 Clinical Features of Acute Hepatitis E

Incubation period of 2–10 wk
Varying clinical manifestations:
Anicteric hepatitis
Icteric hepatitis
Severe hepatitis leading to fulminant hepatic failure
Inapparent, asymptomatic infection
Clinical illness similar to that with other types of acute viral hepatitis (except among pregnant women)
Milder illness in children
Low mortality rate (0.07%–0.6%) except in pregnant women

From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

BOX E2 Features of HEV Genotypes 1 and 2

Acute infection with no evidence of chronicity
Large outbreaks involving up to several thousand persons in developing countries
Frequent sporadic cases
More common among young adults
Fecal-oral transmission, usually through contaminated water
Highest attack rates are among young adults aged 15 to 40 yr, with relative sparing of children
Infrequent person-to-person transmission
No evidence of parenteral or sexual transmission
Greater likelihood of severe disease (liver failure) with high mortality rates (15% to 25%) in pregnant women, especially in the third trimester
Mother-to-newborn (transplacental) transmission is known to occur

From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.

REFERRAL

To gastroenterologist or infectious diseases for correct diagnosis

PEARLS & CONSIDERATIONS

COMMENTS

HEV can become chronic in organ transplant patients on immunosuppressive therapy, and ribavirin appears to produce a sustained virologic response.

PREVENTION

Hepatitis E vaccines are available and appear to be 96% effective.

PATIENT & FAMILY EDUCATION

Travelers to endemic areas should take precautions and drink only potable water and not eat uncooked shellfish, fruits, and vegetables.

TABLE E2 Comparison of Epidemiologic and Clinical Features Associated with HEV Genotypes 1 and 3

Characteristic	Genotype 1	Genotype 3
Epidemiologic patterns of human disease	Large epidemics, small outbreaks, and frequent sporadic cases	A small proportion of cases with sporadic acute hepatitis
Persons affected	Young, otherwise healthy persons; males > females	Mostly elderly, often with other comorbid conditions; males > females
Animal-to-human transmission	Not reported	Demonstrated; a likely mode of transmission through consumption of undercooked meat or close contact with animals
Water-borne transmission	Well known to occur; most common route	Unknown
Animal reservoir	No	Yes (pigs, wild boars, deer)
Severity	Variable severity, including fulminant hepatic failure; severe disease is particularly common in pregnant women	Severity and poor outcome are related to comorbid conditions.
Chronic infection	Not known to occur after acute infection	Immunosuppressed persons; transplant recipients receiving immunosuppressive drugs

From Feldman M et al (eds): *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Saunders.

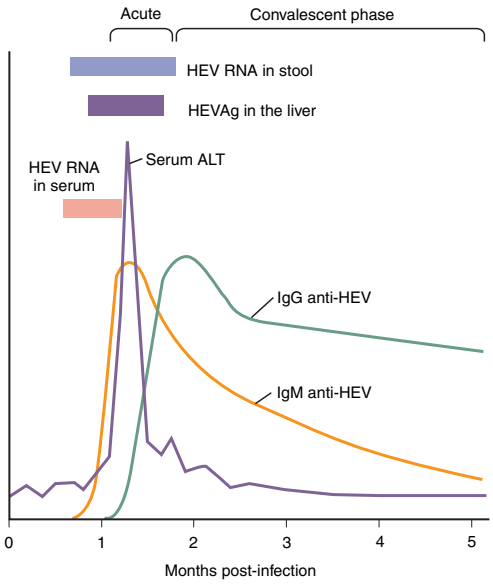

FIG. E2 Typical course of HEV infection (based on studies with human subjects and experimentally infected primates). *anti-HEV,* Antibody to HEV; *Ag,* antigen; *IgG,* immunoglobulin G; *IgM,* immunoglobulin M. BASIC INFORMATION

DEFINITION

Hepatocellular carcinoma (HCC) is a malignant neoplasm of the hepatocytes.

SYNONYMS

Hepatoma
HCC

EPIDEMIOLOGY & DEMOGRAPHICS

HCC is the fifth most common cancer worldwide (~600,000 new cases/yr) and the fourth most common cause of cancer deaths. Incidence varies worldwide:

- 85% of patients with hepatocellular carcinoma have cirrhosis
- Areas with high rates of hepatitis B and C (East Asia, sub-Saharan Africa) have highest incidence
- Males more affected than females, with ratios between 2:1 and 4:1
- Peak incidence: Fifth and sixth decades in Western countries, earlier in areas with perinatal transmission of hepatitis B
- Incidence has grown in the U.S. due to chronic hepatitis C, increasing nonalcoholic fatty liver disease (NAFLD), metabolic syndrome, obesity, and diabetes mellitus
  1. During the past two decades, the incidence in the U.S. doubled. In 2013, an estimated 25,600 cases were recorded. The greatest proportional increase has been among Hispanics and whites between 45 and 60 yr of age.
  2. Mean age of diagnosis approximately 65 yr.
  3. HCC is the fastest-rising cause of cancer-related deaths in the U.S.
  4. The incidence in the U.S. is expected to increase to 38,350 cases by 2020 and 56,200 cases by 2030.
- Risk factors:
  1. Chronic hepatitis B infection accounts for 50% of all cases and most childhood cases
  2. Chronic hepatitis C infection markers are found in 80% to 90% of patients with HCC in Japan and 30% to 50% in the U.S.
  3. Cirrhosis from other causes: Alcoholic liver disease, nonalcoholic steatohepatitis, primary biliary cirrhosis, hemochromatosis, α1-antitrypsin deficiency, and autoimmune hepatitis
  4. Hepatotoxins: Aflatoxin B1
  5. Systemic diseases affecting the liver: Tyrosinemia
  6. Obesity and diabetes mellitus

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- One third of patients are asymptomatic.
- Abdominal pain may be the initial presentation.
- Signs of underlying cirrhosis and portal hypertension are often present.
- Previously compensated cirrhosis with new ascites, encephalopathy, jaundice, or bleeding.
- Paraneoplastic syndromes (hypoglycemia, erythrocytosis, hypercalcemia, severe diarrhea, dermatomyositis) may be present. Box 1 summarizes paraneoplastic syndromes associated with hepatocellular carcinoma.
- Table 1 summarizes symptoms and signs of hepatocellular carcinoma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Metastatic cancers to liver
- Intrahepatic cholangiocarcinoma
- Benign liver neoplasms (adenomas, focal nodular hyperplasia, and hemangiomas)
- Focal fatty infiltration

WORKUP

- History regarding risk factors

BOX 1 Paraneoplastic Syndromes Associated with Hepatocellular Carcinoma

Carcinoid syndrome
Hypercalcemia
Hypertension
Hypertrophic osteoarthropathy
Hypoglycemia
Neuropathy
Osteoporosis
Polycythemia (erythrocytosis)
Polymyositis
Porphyria
Sexual changes—isosexual precocity, gynecomastia, feminization
Thyrotoxicosis
Thrombophlebitis migrans
Watery diarrhea syndrome

(From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

TABLE 1 Symptoms and Signs of Hepatocellular Carcinoma

Symptom	Frequency (%)
Abdominal pain	59-95
Weight loss	34-71
Weakness	22-53
Abdominal swelling	28-43
Nonspecific GI symptoms	25-28
Jaundice	5-26
Sign	
Hepatomegaly	54-98
Ascites	35-61
Fever	11-54
Splenomegaly	27-42
Wasting	25-41
Jaundice	4-35
Hepatic bruit	6-25

GI, Gastrointestinal. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

- Physical examination with attention to signs of chronic liver disease
- Laboratory evaluation and imaging studies
- Imaging studies: Ultrasound for initial testing; 3-phase CT scan or dynamic contrast-enhanced MRI

LABORATORY TESTS

- Liver function tests.
- α-Fetoprotein (AFP) levels can be elevated in 70% of patients. An AFP level >400 ng/ml is highly suggestive of HCC; however, elevations may not be seen in up to 40% of patients with small lesions (1 to 2 cm).
- Paraneoplastic syndromes associated with HCC may cause hypercalcemia, hypoglycemia, and polycythemia.
- Elevated serum HBV DNA level (≥10,000 copies/ml) is a strong risk predictor of HCC independent of HBeAg, serum aminotransferase level, and liver cirrhosis.

IMAGING STUDIES

Ultrasound (US), CT scan (Fig. E1), or MRI. Ultrasound is most commonly used as a screening test for HCC in high-risk patients every 6 mo. Fig. E2 shows a laparoscopic view of a cirrhotic liver with a nodular hepatoma.

The following imaging modalities are recommended based on US findings:

- Hepatic lesion <1 cm needs to be followed with a repeat US every 3 mo to ensure the lesion does not change in size. If stable for 24 mo, the interval for US can be increased to every 6 mo.
- Hepatic lesion >1 cm needs further confirmatory imaging with either a CT scan or an MRI scan. If the chosen imaging modality shows characteristics typical of HCC (hypervascular in the arterial phase with washout in the portal venous or delayed phase) the diagnosis of HCC is confirmed with no need for additional diagnostic testing or biopsy. If the imaging modality is inconclusive or atypical for HCC, then the alternate imaging test must be performed. If the second imaging modality is also inconclusive, an image-guided biopsy is recommended.

BIOPSY: Percutaneous biopsy under ultrasound or CT scan is obtained in the event that imaging studies are nondiagnostic or atypical for HCC, or if no cirrhosis is present. Negative biopsy results should be followed and the hepatic nodule reassessed every 3 to 6 mo until it is no longer seen, enlarges, or shows diagnostic characteristics.

SCREENING: Screening high-risk patients with US every 6 mo is currently recommended to identify early-stage HCC. The use of AFP in addition to US is debatable; though it does increase detection rate it also increases false-positive results. The use of AFP alone should be discouraged due to limited sensitivity and specificity. Patients on transplant waiting lists should be regularly screened for HCC because in the U.S. the development of HCC gives increased priority for liver transplantation. Screening for HCC is recommended in the following groups:

- Hepatitis B carriers (HBsAg positive): Asian males >40 yr, Asian females >50 yr, all cirrhotic hepatitis B carriers, family history

These proofs may contain color figures. Those figures may print black and white in the final printed book if a color print product has not been planned. The color figures will appear in color in all electronic versions of this book.

of HCC and North American blacks/Africans older than age 20 yr
- Cirrhosis (nonhepatitis B): Hepatitis C, alcoholic cirrhosis, hemochromatosis, primary biliary cirrhosis, and possibly α1-antitrypsin deficiency, autoimmune hepatitis, and nonalcoholic steatohepatitis

STAGING: The commonly used Barcelona Clinic Liver Cancer (BCLC) staging system includes patient performance status, cancer symptoms, number and size of nodules, and liver function. The TNM staging classification is described in Table 2.

Treatment is determined according to stage (Fig. 3):
- Early stage (A): Asymptomatic single tumor 5 cm or 3 nodules, each ≤3 cm
- Intermediate stage (B): Patients with tumors that exceed early criteria but do not yet show cancer-related symptoms, vascular invasion, or metastases
- Advanced stage (C): Patients with mild cancer-related symptoms and/or vascular invasion or extrahepatic spread
- End-stage (D): Patients with advanced, symptomatic disease

Rx TREATMENT

- Treatment options for hepatocellular carcinoma are summarized in Table 3. Fig. 4 describes a treatment algorithm for HCC.
- Early stage: Curative treatment (surgical resection or liver transplantation). Patients who have a single lesion can be offered surgical resection if they are noncirrhotic or have cirrhosis with well-preserved liver function, normal bilirubin, and no significant portal hypertension. Liver transplantation is an effective option for patients with HCC corresponding to the Milan criteria (Table 4). Living donor transplantation can be offered for HCC if the waiting time is expected to be long. Local ablation is safe and effective therapy for patients who cannot undergo resection or as a bridge to transplantation. With these options, survival at 5 yr ranges from 50% to 70%. Radiofrequency ablation (RFA) is used in patients with early HCC who are not surgical candidates, and very high local control rates at 2 yr are obtained (>90%), but eventual recurrence rates can approach 70% at 5 yr.
- Intermediate stage: Transarterial chemoembolization (TACE) is recommended as first-line, noncurative therapy for nonsurgical patients with large/multifocal HCC who do not have vascular invasion or extrahepatic spread. More recently, transarterial use of selective internal radiation therapy (SIRT) with yttrium-90 radiolabeled glass microspheres is an alternative to traditional TACE approaches in this setting. Median survivals exceed 2 yr.
- Advanced stage: Palliative targeted therapy, immunotherapy, or clinical trials are used in this stage. Sorafenib and lenvatinib are oral multikinase inhibitors, which are both approved as standard first-line therapy options.
- In patients who have previously received first-line targeted therapy, the oral multikinase inhibitors regorafenib and cabozantinib have shown improved survival. In addition, the immune checkpoint inhibitors nivolumab and pembrolizumab have demonstrated improved survival when used in the second-line setting.
- The antiangiogenic agent ramucirumab was recently approved in the second-line treatment of HCC patients previously treated with sorafenib.

DISPOSITION

- For resectable HCC, the 5-yr survival after liver transplantation is 50% to 70% and 30% to 50% with surgical resection. For unresectable HCC, the overall prognosis is poor.
- Tumor size is an independent prognostic factor for resected small HCC (≤50 mm in diameter). Patients with tumors of 0 to 35 mm diameter have a better 60-mo HCC specific survival rate than do those with larger tumors (36 to 50 mm).[1]
- In the U.S. the 5-yr overall survival rate for HCC is approximately 10%.

REFERRAL

Multidisciplinary gastrointestinal cancer team for treatment planning

PEARLS & CONSIDERATIONS

- Universal hepatitis B vaccination in children in endemic areas has been shown to decrease the incidence of HCC.
- Treatment of patients with chronic hepatitis B–associated cirrhosis with lamivudine reduces the incidence of HCC. Treatment with entecavir in chronic hepatitis B-HCC can improve hepatic function and MELD score.
- Treatment with interferon-based therapy in patients with noncirrhotic hepatitis C reduces risk of HCC in patients demonstrating a sustained viral response.
- HCC screening is recommended in high-risk patients because curative therapies are available only for small and early HCC.

TABLE 2 Hepatocellular Carcinoma TNM Staging Classification and Milan Criteria for Liver Transplantation

	T stage
T_x	The primary tumor is not assessable
T_0	No tumor is present
T_1	A single tumor (of any size) without blood vessel invasion
	T_{1a}: Solitary tumor <2 cm (greatest dimension) without vascular invasion
	T_{1b}: Solitary tumor >2 cm (greatest dimension) without vascular invasion
T_2	A single tumor >2 cm *with* vascular invasion or multiple tumors (none >5 cm)
T_3	Multiple tumors, any more >5 cm
T_4	Tumor(s) invading a major branch of the portal or hepatic vein with direct invasion of adjacent organs including the diaphragm (other than gallbladder) or with perforation of the visceral liver peritoneum
	N stage
N_x	The lymph nodes are not assessable
N_0	There is no regional nodal involvement
N_1	There is regional nodal involvement
	M stage
M_0	There is no distant tumor spread
M_1	There is distant tumor spread

Milan criteria for liver transplantation

1 tumor ≤5 cm in diameter, or
Up to 3 tumors ≤3 cm in diameter
+ No vascular invasion
+ No extrahepatic disease

Note

The TNM staging classification does not consider the background liver function, which is often impaired in cirrhosis and will affect treatment options and prognosis. Other staging systems consider both disease extent and liver function, but have not been compared accurately against one another:
- Barcelona Clinic Liver Cancer (BCLC) system
- Cancer of the Liver Italian Program (CLIP) system
- Okuda system

TABLE 4 Milan Criteria of Eligibility for Liver Transplantation

Presence of a tumor ≤5 cm in diameter in patients with single hepatocellular carcinomas
Or
≤3 tumor nodules, each 3 cm or less in diameter, in patients with multiple tumors

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 10, Philadelphia, 2011, Saunders.

- Patients diagnosed with HCC with an AFP >1000 are at increased risk for recurrence after transplantation regardless of tumor size.
- There are numerous ongoing trials with tyrosine kinase inhibitors and monoclonal antibodies for advanced HCC in patients who are intolerant or resistant to sorafenib. The future of therapy for advanced HCC will likely lead to the personalized combination of multiple agents targeting different oncogenic pathways to optimize treatment success.

Hepatopulmonary Syndrome ALG

BASIC INFORMATION

DEFINITION

Hepatopulmonary syndrome (HPS) is defined by the presence of (1) liver disease (usually chronic), (2) reduced arterial oxygenation, and (3) evidence of intrapulmonary vascular dilations (IPVDs).

SYNONYM

HPS

ICD-10CM CODE
K76.81 Hepatopulmonary syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Between 4% and 47% of patients with cirrhosis; the wide range is due to lack of diagnostic criteria
PREDOMINANT SEX AND AGE: No data on age or gender prevalence
GENETICS: New data suggest that polymorphisms in genes involved in the regulation of angiogenesis are associated with increased HPS risk.
RISK FACTORS: HPS occurs with any degree or etiology of liver disease but is more prevalent in patients with established cirrhosis and portal hypertension. There is no clear relationship between severity of hepatic dysfunction and level of systemic hypoxemia.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Dyspnea
- Platypnea: Worsened dyspnea when sitting upright compared with supine position due to further ventilation-perfusion mismatch
- Orthodeoxia: Decreased Pa_{O_2} when the patient is sitting upright compared with supine position due to ventilation-perfusion mismatch
- Increased spider angiomata
- Signs of severe hypoxemia (e.g., cyanosis and clubbing of the digits)

ETIOLOGY

Dilation of intrapulmonary arterioles and dilated vascular channels between pulmonary arteries and veins leads to a ventilation-perfusion mismatch and right-to-left shunting. Research shows that nitric oxide (NO) plays a role in vasodilation. The relationship of vasodilation to liver disease is unclear. Fig. E1 illustrates a proposed pathophysiology of hepatopulmonary syndrome. New areas of research include endothelin-1, which is produced by proliferating cholangiocytes, pulmonary angiogenesis, and opiate receptors' influence on NO production.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Portopulmonary hypertension
- Cavopulmonary anastomosis
- Hereditary hemorrhagic telangiectasia (Rendu-Osler-Weber syndrome)
- Chronic lung disease (e.g., COPD or pulmonary fibrosis) with coexisting liver disease

WORKUP

- Diagnosis should be suspected in patients with cirrhosis who develop hypoxemia in the absence of other causes (e.g., COPD, thromboembolism).
- Workup includes lab testing and imaging studies (see following), but diagnosis is based on clinical findings.

LABORATORY TESTS

- Arterial blood gas while breathing room air, both supine and erect; Pa_{O_2} <80 mm Hg in the absence of an alternative cause or A-a gradient ≥15 mm Hg (or ≥20 mm Hg in those ≥65 yr old).
- Pulmonary function tests will show nonspecific reduction in DLco.

IMAGING STUDIES

- The most effective screening tool is a transthoracic echocardiogram with bubble study to rule out right-to-left cardiac shunt; microbubble opacification in the left atrium after three to eight heartbeats suggests vasodilation of the pulmonary vascular bed.
- Chest x-ray may show nonspecific bibasilar interstitial pattern.
- Scintigraphic perfusion scanning: Technetium-99m–labeled albumin found in the brain or spleen indicates dilated pulmonary vasculature or cardiac right-to-left shunt.
- Pulmonary angiography is rarely used unless there is a potential to embolize arteriovenous malformations (AVM).

TREATMENT

Ideal treatment would be targeted against pulmonary vasodilation. Most medications have targeted NO production, the activity of NO synthase or endothelin-1, pulmonary angiogenesis, or even bacterial translocation, but no controlled trials exist. Liver transplantation is the only successful treatment, which leads to improvement in gas exchange or complete resolution in gas exchange in the majority of patients. However, severe hypoxemia with Pa_{O_2} <50 mm Hg has been associated with high posttransplant mortality. Some studies have shown benefit of transjugular intrahepatic portosystemic shunting (TIPS), although it is not currently an established treatment. Coil embolization in the setting of pulmonary AVMs is another possible area of treatment.

NONPHARMACOLOGIC THERAPY

Oxygen to correct hypoxemia; Pa_{O_2} will partially correct with administration of supplemental O_2.

ACUTE GENERAL Rx

Correct hypoxemia with supplemental O_2

CHRONIC Rx

- Liver transplantation is the only successful treatment; the majority of patients show improvement in oxygenation at 1 yr after transplant. There are some data showing

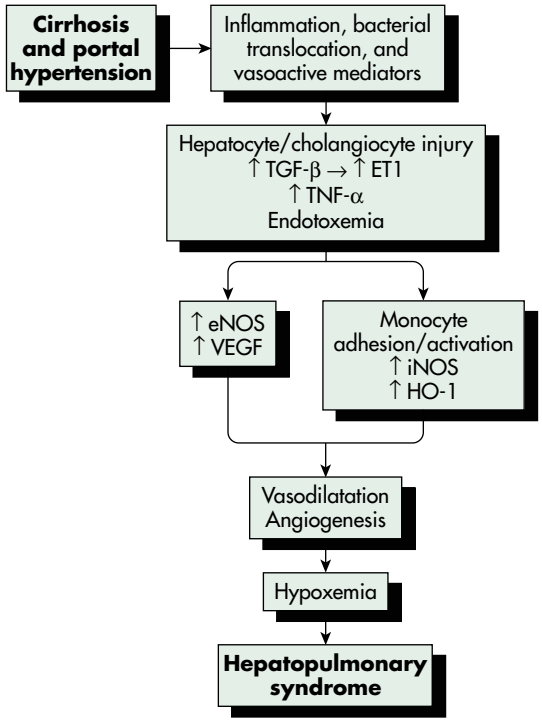

FIG. E1 Proposed pathophysiology of hepatopulmonary syndrome. *eNOS*, Endothelial nitric oxide synthase; *ET1,* endothelin-1; *HO-1,* heme oxygenase; *iNOS,* inducible nitric oxide synthase; *TGF-β,* transforming growth factor-β; *VEGF*, vascular endothelial growth factor. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

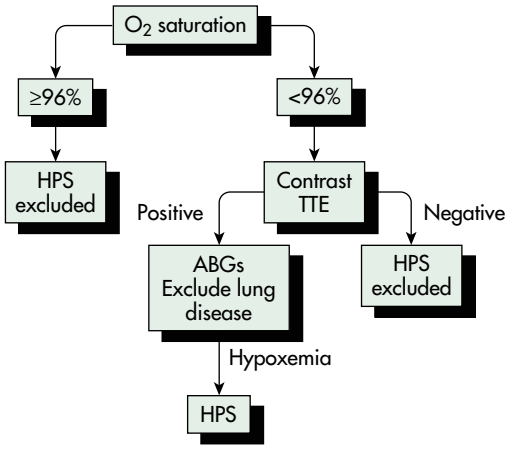

FIG. E2 Approach to screening for hepatopulmonary syndrome *(HPS)* in potential candidates for liver transplantation. *ABG*, Arterial blood gas; *TTE*, transthoracic echocardiography. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

worse outcomes for patients with severe HPS (Pao_2 <50 mm Hg), but mortality appears to be improving. Fig. E2 illustrates an approach to screening for hepatopulmonary syndrome in potential candidates for liver transplantation.

COMPLEMENTARY & ALTERNATIVE MEDICINE

One study suggested that garlic supplements might reduce the A-a gradient in patients with HPS. Studies of diets containing low amounts of L-arginine have not shown benefit.

DISPOSITION

The diagnosis of HPS confers a poor prognosis. Patients with HPS have high mortality and shorter median survival than other patients with liver disease, even after adjusting for the severity of liver disease. According to one natural history study, compared to patients with similar severities of liver disease and comorbidities whose 5-yr survival was estimated at 63%, patients with HPS had a 5-yr survival rate of only 23%.

REFERRAL

- Referral to pulmonologist to help in establishing diagnosis
- Referral to a liver transplant center

PEARLS & CONSIDERATIONS

COMMENTS

Consider the diagnosis of HPS in patients with cirrhosis who present with dyspnea without signs of pulmonary edema from fluid overload.

AUTHORS: **Kathleen Doo, MD,** and **Samaan Rafeq, MD**

Hepatorenal Syndrome (PTG)

BASIC INFORMATION

DEFINITION

Hepatorenal syndrome (HRS) is a functional cause of acute kidney injury (AKI) that occurs in the setting of severe acute or chronic liver disease, most commonly with cirrhosis and portal hypertension. HRS develops as a result of reduced renal perfusion caused by hemodynamic alterations in arterial circulation, as well as overactivity of endogenous vasoactive systems.

In HRS, liver dysfunction leads to increased production or activity of vasodilators. Vasodilation is most pronounced in the splanchnic circulation and, combined with cardiac dysfunction, results in systemic hypotension. Disturbed vasoconstrictor-vasodilator balance in the kidney favoring vasoconstrictors precipitates intense renal arteriolar vasoconstriction, renal cortical hypoperfusion, and AKI. (see Fig. E1). Fig. E2 illustrates the proposed pathophysiology and triggers of HRS. It is now recognized that HRS not only involves circulatory dysfunction but also systemic inflammation.

There are two types of HRS (see Table E1). The International Club of Ascites (ICA) recently revised the nomenclature and diagnosis of type 1 HRS (HRS-1), renaming it HRS-acute kidney injury (HRS-AKI), and type 2 HRS (HRS-2), renaming it HRS–nonacute kidney injury (HRS-NAKI).

- Type 1: Acute and rapid deterioration in kidney function (see Table E2)
- Type 2: Moderate stable chronic kidney disease (CKD) (average serum creatinine, 1.5 mg/dl [133 μmol/L])

SYNONYMS

Hepatorenal failure
Hepatic nephropathy
HRS
Oliguric renal failure of cirrhosis

ICD-10CM CODES

K76.7	Hepatorenal syndrome, hepatorenal failure
Z87.19	History of hepatorenal syndrome
Z84.1	Family history of hepatorenal syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

The probability of HRS in patients with cirrhosis is 18% at 1 yr and 39% at 5 yr. HRS is associated with poor prognosis. HRS type 1 is associated with >90% mortality in 3 mo, with higher mortality conferred by a Model for End-stage Liver Disease (MELD) score >30 and higher stages of AKI. HRS type 2 is associated with 30% mortality in 3 mo and 60% in 1 yr. Although the cause of liver failure or MELD score does not predict the development of HRS, MELD score predicts mortality when HRS has occurred. Dilutional hyponatremia is an independent risk factor for HRS.

PHYSICAL FINDINGS & CLINICIAL PRESENTATION

There are no specific physical findings associated with HRS, although it is usually associated with signs and symptoms of acute or chronic decompensated liver failure, such as hypotension, jaundice, spider angiomata, splenomegaly, ascites, fetor hepaticus, edema, asterixis, encephalopathy, or coma. Usually, HRS is accompanied by oliguria and a bland urine sediment. However, a nonoliguric state or an active urine sediment (blood, casts, and/or protein) does not exclude the diagnosis of HRS.

PRECIPITANTS

Precipitating events are identified in 70% to 100% of cases of HRS. Contributory factors include bacterial infection, alcoholic hepatitis, excessive laxative or NSAID use, GI bleeding, or large-volume paracentesis without albumin administration. Unlike HRS, prerenal azotemia, irrespective of its etiology (diuresis or other fluid removal), improves with cessation of diuretic therapy and/or volume resuscitation. Nevertheless, HRS may present in the absence of a clear precipitating factor. Recent studies suggest that, among those not listed for liver transplant, mortality rates are extremely high in patients with either HRS or acute tubular necrosis (ATN).

DIAGNOSIS

HRS is a diagnosis of exclusion. The revised diagnostic criteria for HRS are summarized in Table E3.

DIFFERENTIAL DIAGNOSIS

- Prerenal azotemia: Must be excluded or treated appropriately before establishing a diagnosis of HRS. Prerenal azotemia typically responds to volume expansion and cessation of diuretic therapy. Both prerenal azotemia and HRS are often associated with fractional excretion of sodium (FE_{Na}) <1%.
- ATN: Urine sodium >30 mEq/L, FE_{Na} >1.5%, urine-to-plasma creatinine ratio <30, urine-to-plasma osmolality ratio = 1; urine sediment reveals muddy brown casts and cellular debris. There is no significant response to sustained plasma expansion.
- Other: Renal artery or vein thrombosis; cardiorenal syndrome; urinary tract obstruction; glomerulonephritis; and toxicity from drugs, organic solvents, heavy metals, heme pigments, and intravenous contrast medium.

WORKUP

Acute azotemia and oliguria in the setting of liver disease requires laboratory evaluation to differentiate HRS from ATN. Extracellular fluid volume challenge may be required to differentiate HRS from prerenal azotemia. Diagnostic paracentesis should be done to rule out spontaneous bacterial peritonitis (SBP). Serum creatinine and BUN are poorly sensitive markers of kidney function in cirrhosis. Serum creatinine in patients with cirrhosis is also affected by the following factors:

- Decreased formation of creatinine from creatine in muscles, secondary to muscle wasting
- Increased renal tubular secretion of creatinine
- Increased volume of distribution causing dilution of SCr
- Interference with assays for SCr by elevated bilirubin

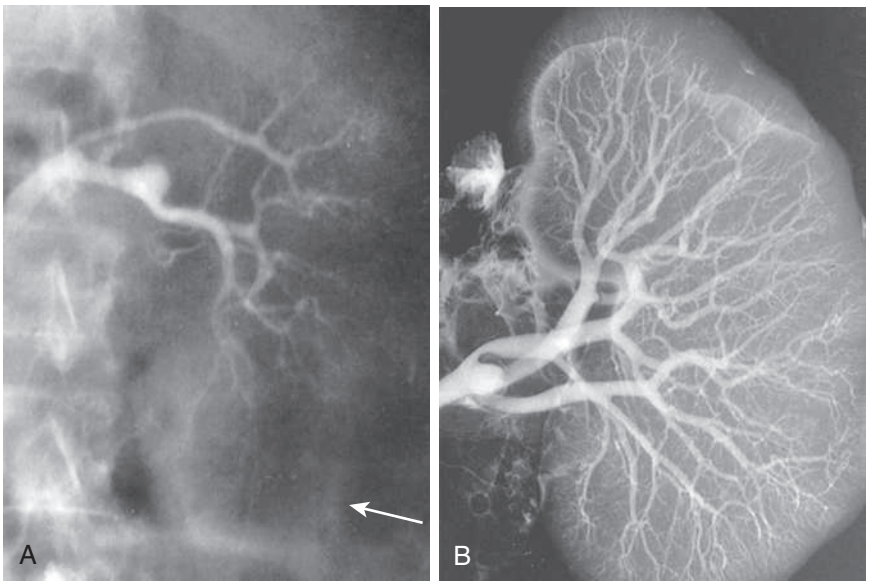

FIG. E1 Circulatory dysfunction in hepatorenal syndrome (HRS). A, Renal angiogram (the *arrow* marks edge of the kidney). **B,** The angiogram carried out in the same kidney at autopsy. Note complete filling of the renal arterial system throughout the vascular bed to the periphery of the cortex. The vascular attenuation and tortuosity seen previously **(A)** are no longer present. The vessels are also histologically normal. This finding indicates the functional nature of the vascular abnormality in HRS. (From Floege J et al: *Comprehensive clinical nephrology,* ed 4, St Louis, 2010, Saunders.)

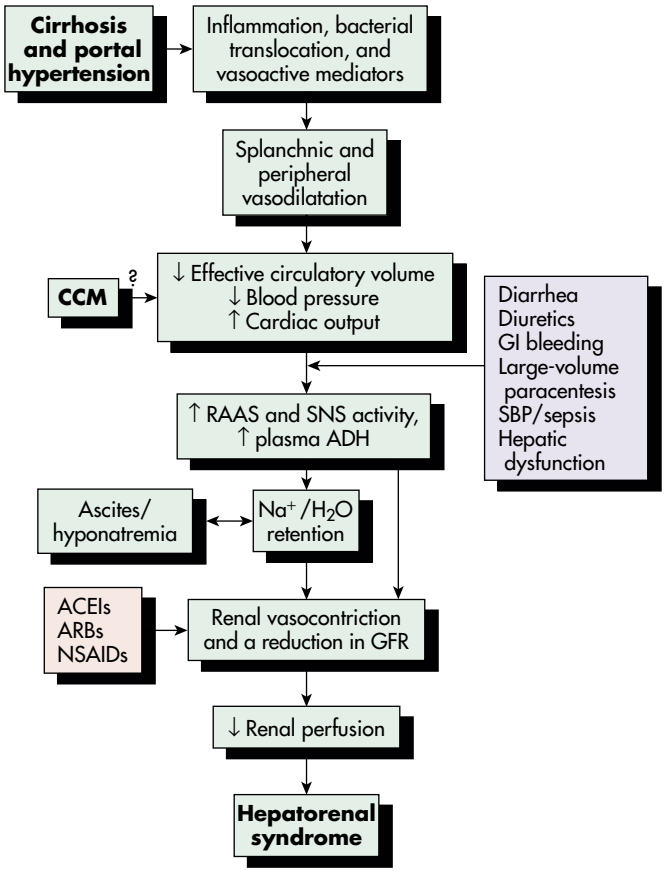

FIG. E2 Proposed pathophysiology and triggers of hepatorenal syndrome. *ACEI,* Angiotensin-converting enzyme inhibitor; *ADH,* antidiuretic hormone; *ARB,* angiotensin receptor blocker; *CCM,* cirrhotic cardiomyopathy; *GFR,* glomerular filtration rate; *NSAID,* nonsteroidal anti-inflammatory drug; *RAAS,* renin-angiotensin-aldosterone system; *SBP,* spontaneous bacterial peritonitis; *SNS,* sympathetic nervous system. (From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

TABLE E1 Definition of Hepatorenal Syndrome

Type 1 HRS: HRS-AKI

Acute and rapid deterioration in kidney function: An acute increase in serum creatinine of ≥0.3 mg/dl within 48 hours or ≥50% from a stable baseline serum creatinine within 3 mo (presumed to have developed within the past 7 days when no prior readings are available).
Occurs in parallel with the cirrhosis-associated failure of other organs or systems (e.g., coagulopathy, hepatic encephalopathy).
In cirrhosis, is a form of acute-on-chronic liver failure.
Frequently follows a precipitating event, mainly bacterial infection; rapidly fatal without treatment.
Mean survival of 2 to 3 wk. Renal replacement therapy does not prolong life without liver transplantation.

Type 2 HRS: HRS-NAKI

HRS-AKD	Hepatorenal syndrome-acute kidney disease: a) eGFR <60 ml/min per 1.73 m^2 for <3 mo in the absence of other (structural) causes; *or* b) SCr increase <50% using the last available outpatient value within 3 mo
HRS-CKD	Hepatorenal syndrome-chronic kidney disease: eGFR <60 ml/min per 1.73 m^2 for 3 mo in the absence of other (structural) causes

Moderate stable CKD.
Mean survival of 6 mo.

AKI, Acute kidney injury; *CKD,* chronic kidney disease; *eGFR,* estimated glomerular filtration rate; *HRS,* hepatorenal syndrome; *NAKI,* nonacute kidney injury; *SCr,* serum creatinine.
From Fernández J, Arroyo V: Hepatorenal syndrome. In Johnson RJ et al (eds): *Comprehensive clinical nephrology,* ed 5, Philadelphia, 2015, Saunders, pp 873-882.

LABORATORY TESTS

- Serum electrolytes (serum sodium <135 mEq/L), blood urea nitrogen, creatinine, and osmolality
- Urinalysis, urine sodium, urine creatinine, urine osmolality
- Urine sodium <10 mEq/L, FE_{Na} <1%, urine-to-plasma creatinine ratio >30, urine plasma-to-urine osmolality ratio >1.5, bland urine sediment. FE_{Na} does not adequately differentiate HRS from other common etiologies of AKI in liver dysfunction, but only a minority of patients with HRS have high urine sodium concentrations

IMAGING STUDIES

Kidney, bladder, and ureter ultrasound may be indicated if obstructive uropathy is suspected. Duplex Doppler ultrasonography may show increased renal resistive indices (RI) in hilar, medullary, and cortical areas and disappearance of the RI gap (difference between interlobar and cortical RI), indicating reduction of renal blood flow. CT may be required to diagnose occult infection(s), and prophylaxis directed at preventing contrast-associated nephropathy is recommended.

Rx TREATMENT

ACUTE GENERAL Rx

- Box E1 summarizes the management of HRS. Avoidance of precipitating factors (Table E4) and their appropriate therapy are cornerstones of HRS management.
- Patients who have survived an episode of SBP should receive long-term prophylaxis with daily norfloxacin or trimethoprim/sulfamethoxazole.
- Improvement in liver function due to partial resolution of the primary disorder or successful liver transplantation is the optimal treatment. Liver transplantation leads to resolution of HRS type 1 in 76% of cases.
- Splanchnic vasoconstrictor agents (e.g., terlipressin, norepinephrine, and midodrine combined with octreotide). Note that terlipressin, a vasopressin analog, has not yet been approved for prescription in the United States or Canada.
- Dopamine and prostaglandins are generally ineffective in treating patients with HRS.

PHARMACOLOGIC THERAPY

Most therapy is centered on the use of vasoconstrictor therapy and albumin resuscitation targeted at the reversal of splanchnic arterial vasodilation.

NONPHARMACOLOGIC THERAPY

- Liver transplantation alone for candidates with type I HRS for <4 wk, and simultaneous liver-kidney transplantation for those at risk of nonrecovery of kidney function.
- Transjugular intrahepatic portosystemic shunt (TIPS) for patients with HRS-2 and refractory ascites.
- Renal replacement therapy as a bridge to liver transplantation.

REFERRAL

Referral for hepatology, nephrology, and liver transplantation as indicated

PEARLS & CONSIDERATIONS

- Serum creatinine remains a main biomarker in diagnosis of HRS; there is a potential role

of new urinary biomarkers in the differential diagnosis for AKI in patients with cirrhosis.
- Outcomes are poor in both HRS-AKI and ATN-AKI. Differentiation between these two diagnoses is of questionable clinical importance.
- The mortality of patients with liver failure who require renal replacement therapy is high and is similar in HRS and ATN. However, renal recovery and patient survival 1 and 5 yr after liver transplantation are significantly worse for patients with AKI secondary to ATN versus HRS.
- Vasopressor agents and volume resuscitation with albumin remain a mainstay of medical management.
- In severely ill patients who are not candidates for liver transplantation, dialysis does not improve outcomes.

AUTHORS: **Maria Andrievskaya, MD,** and **James E. Novak, MD, PhD**

TABLE E2 Hepatorenal Syndrome Type 1 Classified by Acute Kidney Injury (AKI) Stage according to the International Club of Ascites (ICA) and Acute Kidney Injury Network (AKIN) Criteria

Risk/Stage 1	Increase in SCr >1.5- to 2-fold from baseline; or by >0.3 mg/dl (26.5 μmol/L) Increase in SCr of 50% or more to a final value of >1.5 mg/dl (133 μmol/L)
Injury/Stage 2	Increase in SCr >2- to 3-fold from baseline
Failure/Stage 3	Increase in SCr >3-fold from baseline; or SCr >4 mg/dl (353.6 μmol/L) with an acute increase of ≥0.5 mg/dl (44 μmol/L); or initiation of renal replacement therapy

SCr, Serum creatinine.
From Angeli P et al: Diagnosis and management of acute kidney injury in patients with cirrhosis: revised consensus recommendations of the International Club of Ascites, *J Hepatol* 62:968-974, 2015.

TABLE E3 Revised Diagnostic Criteria for Hepatorenal Syndrome Type of Acute Kidney Injury (HRS-AKI) in Patients with Cirrhosis

- **Cirrhosis; acute liver failure; acute on chronic liver failure**
- Diagnosis of AKI according to International Club of Ascites criteria*
- No improvement in kidney function after 48 consecutive hours of diuretic withdrawal and plasma volume expansion with albumin 1 g per kg body weight per day (maximum dose, 100 g per day)
- Absence of shock
- No current or recent use of nephrotoxic drugs (e.g., nonsteroidal anti-inflammatory drugs, aminoglycosides, iodinated contrast media)
- No macroscopic signs of structural kidney injury, defined as:
  - Absence of proteinuria (>500 mg/day)
  - Absence of microhematuria (>50 red blood cells per high-power field)
  - Normal findings on renal ultrasonography

*This criterion would not be included in cases of known pre-existing structural chronic kidney disease (e.g., diabetic or hypertensive nephropathy).
From Angeli P et al: Diagnosis and management of acute kidney injury in patients with cirrhosis: revised consensus recommendations of the International Club of Ascites, *J Hepatol* 62:968-974, 2015.

BOX E1 Management of Hepatorenal Syndrome (HRS)

- Measures to prevent variceal bleeding (e.g., beta blockers, band ligation)
- Treatment of severe alcoholic hepatitis
- Prevention of HRS
  - Avoid intravascular volume depletion (diuretics, excessive lactulose, GI bleeding, large-volume paracentesis without adequate volume repletion)
  - Angiotensin-converting enzyme inhibitors and angiotensin receptor blockers should be avoided or used with caution in patients with cirrhosis and ascites. Judicious management of nephrotoxins (NSAIDs, antibiotics). Prompt diagnosis and treatment of infections (SBP, sepsis)
  - SBP prophylaxis: Long-term use of norfloxacin (or trimethoprim/sulfamethoxazole) can be justified if the ascitic fluid protein <1.5 g/dl along with CKD (creatinine >1.2 mg/dl, BUN >25 mg/dl or serum Na <130 mmol/L) or liver failure (Child score >9 and bilirubin >3 mg/dl) (Class I, Level A)
  - Avoid use of proton pump inhibitors without indications as can precipitate SBP.
- Treatment of HRS
  - Stop all nephrotoxic or volume-depleting agents (ACEIs, ARBs, NSAIDs, diuretics)
  - Antibiotics for infections
  - IV albumin—bolus of 1 g/kg/day on presentation (maximum dose, 100 g daily). Continue at dose of 20–60 g daily as needed to maintain central venous pressure 10–15 cm H_2O
  - Vasopressor therapy (in addition to albumin):
    - Terlipressin*—start at 1 mg IV every 4 h and increase up to 2 mg IV every 4 h if baseline serum creatinine level does not improve by 25% at day 3 of therapy

    OR
    - Midodrine and octreotide—begin midodrine at 2.5–5 mg orally 3 times daily and increase to a maximum dose of 15 mg 3 times daily. Titrate to a MAP increase of at least 15 mm Hg; begin octreotide at 100 μg subcutaneously 3 times daily and increase to a maximum dose of 200 μg subcutaneously 3 times daily, or begin octreotide as a 25-μg IV bolus and continue at a rate of 25 μg/h

    OR
    - Norepinephrine—0.1 to 0.7 μg/kg per minute as an IV infusion. Increase by 0.05 μg/kg per minute every 4 h and titrate to a MAP increase of at least 10 mm Hg
    - Duration of vasopressor treatment is generally a maximum of 2 wk until reversal of hepatorenal syndrome or liver transplantation
- Evaluate patient for liver transplantation

*Not available in the U.S.
ACEI, Angiotensin-converting enzyme inhibitor; *ARB,* angiotensin receptor blocker; *BUN,* blood urea nitrogen; *CKD,* chronic kidney disease; *GI,* gastrointestinal; *IV,* intravenous; *MAP,* mean arterial pressure; *NSAID,* nonsteroidal anti-inflammatory drug; *SPB,* spontaneous bacterial peritonitis.
From Feldman M et al: *Sleisenger and Fortran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

TABLE E4 Prevention of Acute Kidney Injury in Patients with Cirrhosis

Risk Factors	Preventive Approaches
Hepatorenal syndrome development	Judicious use of diuretics and lactulose to avoid hypovolemia Antibiotic prophylaxis following GI bleeding Albumin administration during large volume paracentesis (6 to 8 g/L of ascitic fluid removed) Spontaneous bacterial peritonitis (SBP) prophylaxis in patients with low-protein ascites Early recognition and treatment of SBP with antibiotics and albumin at the dose of 1.5 g per kg of body weight at the time of diagnosis of SBP and 1 g per kg of body weight at the third day of treatment
Nephrotoxic medication exposure	Avoid nephrotoxic medications if possible Appropriate drug dosing based on pharmacokinetics and close monitoring of drug toxicity, early recognition of drug-induced AKI, and discontinuation of offending agent if possible Use of lipid formulations of amphotericin B rather than conventional formulations of amphotericin B Use of azole antifungal agents and/or the echinocandins rather than conventional amphotericin B, if equal therapeutic efficacy can be assumed
Radiocontrast exposure	Consider alternative imaging methods or avoidance of IV contrast if possible Use of low or iso-osmolar agents with lowest volume possible IV volume replacement prior to contrast exposure
Intraabdominal hypertension	Paracentesis, with coadministration of albumin, in patients with tense ascites

AKI, Acute kidney injury; *IV,* intravenous.
From Ronco C et al: *Critical care nephrology,* ed 3, Philadelphia, 2019, Elsevier.

BASIC INFORMATION

DEFINITION

Hereditary breast and ovarian cancer syndrome (HBOC) patients carry a significant cancer-associated alteration in the *BRCA1* and/or *BRCA2* gene. These genetic mutations can confer a heightened risk of malignancy in the breast, ovary, fallopian tube, and peritoneum in women and an elevated risk of prostate and breast cancer in men. Additionally, the risk of pancreatic cancer and skin cancer are elevated for both men and women. Another condition, Lynch syndrome, or hereditary nonpolyposis colorectal cancer (HNPCC), is associated with an increased risk of endometrial cancer and ovarian cancer in women and cancer of the colon, stomach, pancreas, and small bowel in both women and men. Patients with Lynch syndrome carry significant pathogenic alterations in five genes, as noted below.

The risk for a particular verified genetically associated cancer is significantly greater than the cancer risk associated with the general population or with one's personal and/or family cancer history alone, without a positive genetic test. Frequently, a cancer that is associated with a heritable genetic mutation presents at a younger age than that seen in the general population is a relatively rare type of cancer and/or affects multiple same-side family members. Identifying carriers can significantly reduce the morbidity and mortality of the patient and her/his close family members.

SYNONYMS

Hereditary breast and ovarian cancer syndrome (HBOC)
Lynch syndrome/hereditary nonpolyposis colorectal cancer (HNPCC)
Hereditary cancer syndrome

ICD-10CM CODES

Z84.81	Family history of carrier of genetic disease
Z80.3	Family history of malignant neoplasm of breast
Z80.41	Family history of malignant neoplasm of ovary
Z80.49	Family history of malignant neoplasm of other genital organs (uterus, vagina, for example)
Z15.01	Genetic susceptibility to malignant neoplasm of breast
Z15.02	Genetic susceptibility to malignant neoplasm of ovary

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Overall, an estimated 6% to 10% of gynecologic cancers are heritable. Approximately 7% to 10% of the estimated 235,000 new breast cancer cases are likely to be associated with heredity. Inherited pathogenic *BRCA 1, 2* mutations account for an estimated 11% to 15% of ovarian cancer cases. Less than 1% of the general population has a pathogenic mutation in the *BRCA 1* or *2* gene. As noted above, Lynch syndrome–associated mutations increase ovarian and uterine cancer as well as colorectal (up to 5% of colorectal cancers are considered heritable), pancreatic, and gastric cancers. This article will, however, focus on gynecologic disease. Tables 1 and 2 summarize genes associated with hereditary breast and ovarian cancer predisposition.

PREDOMINANT SEX AND AGE: Although females are predominantly affected, males who carry deleterious mutations in *BRCA 1, 2* are at a significantly higher risk for cancer. Both sexes can transmit the altered gene to their offspring.

GENETICS: The transmission pattern is autosomal dominant. A child whose father or mother has a *BRCA* mutation has a 50% chance of inheriting that genetic mutation.

RISK FACTORS: *BRCA1* and *BRCA2* mutations can generate a greater risk of breast cancer than other such well-established factors as increased breast density, history of atypical ductal or lobular hyperplasia, nulliparity, obesity, and family history.

Up to 37% of breast cancer patients and 100% of ovarian/tubal/peritoneal cancer patients are at risk for hereditary breast and ovarian cancer syndrome.

Hereditary Breast and Ovarian Cancer Syndrome (HBOC):

- Individuals with *BRCA1*, *BRCA2* mutations (Fig. 1)
- Red flags (not an exhaustive list) for possible HBOC include personal or family history of:
  1. Personal breast cancer diagnosed at ≤45 yr old
  2. Triple-negative breast cancer (ER-, PR-, Her2-)
  3. Ovarian cancer: Very important factor (mostly papillary serous)
  4. Male breast cancer
  5. Two primary breast cancers
  6. Ashkenazi Jewish ancestry
  7. Breast cancer with ≥2 relatives with an HBOC-associated cancer (breast, ovary, prostate, pancreatic cancers)
  8. A previously identified HBOC mutation
  9. Two or more close relatives with breast cancer, one of whom was diagnosed at age 50 yr or younger

TABLE 1 Genes Associated with Hereditary Breast Cancer Predisposition

Gene	Syndrome	Relative Risk of BC	BC Risk by Age 80 Yr	Associated Cancers
High Penetrance				
BRCA1	HBOC	~15-30	70%	Ovarian, other
BRCA2	HBOC	~10-20	70%	Ovarian, pancreatic, prostate, other
p53	Li-Fraumeni syndrome	100	50% by 60 yr	Soft tissue sarcoma, osteosarcoma, brain tumors, adrenocortical carcinoma, leukemia, other
PTEN	Cowden syndrome	No reliable estimate	70%-80%	Thyroid (follicular and rarely papillary) endometrial, genitourinary, other
	Bannayan-Riley-Ruvalcaba syndrome			
	Proteus			
	Proteus-like syndrome			
STK11	Peutz-Jeghers syndrome	No reliable estimate	30% by age 60	Small intestine, colorectal, uterine, testicular and ovarian sex chord tumors, other
CDH1	Hereditary diffuse gastric carcinoma	~3.25	39%	Lobular breast, diffuse gastric, other
Lower or Moderate Penetrance				
ATM (heterozygote)	Ataxia-telangiectasia in homozygotes	~3	30	Undefined in heterozygotes
CHK2 (CHEK2)	Li-Fraumeni variant	1.5-3	20%-30%	Undefined
PALB2	None known	5	~40	Undefined in heterozygotes

BC, Breast cancer; *HBOC,* hereditary breast and ovarian cancer syndrome.
From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

10. Three or more HBOC-associated cancers at any age

NOTE:

- One half of *BRCA* carriers inherit the mutation from their father.
- Early onset of cancer may be a more important red flag than the number of affected family members, especially if the number of family members is small to begin with.
- Testing criteria (Tables 3 and 4), as per National Comprehensive Cancer Network (NCCN) guidelines, may differ from the red flags noted previously.
- Family history extends to first-, second-, and third-degree relatives.
- Consider Lynch syndrome–associated cancers (e.g., colorectal, gastric, brain, pancreas, small bowel, skin, ureter, renal pelvis, GI polyps), as Lynch syndrome is associated also with ovarian and uterine (endometrial) cancer.
- *BRCA* stands for BReast CAncer.
  1. The majority (84%) of the approximately 7% of breast cancers and 14% of ovarian cancers that result from a heritable mutation are due to a *BRCA1* (52%) and *BRCA2* (32%) gene mutation.
  2. By age 70, in comparison to the 7.3% risk of breast cancer in the general population, or approximately double that risk if one has an affected first-degree relative, *BRCA1* and *BRCA2* mutation carriers have up to an 87% reported risk of developing breast cancer. As opposed to a general-population risk of 2% for developing a second breast primary within 5 yr of a first diagnosis, women with HBOC mutations have a 12% to 27% risk. This risk climbs to a reported 50% (*BRCA2*) and up to 64% (*BRCA1*) by age 70.
  3. By age 70, in contrast to the 0.7% risk of ovarian cancer in the general population, there is a reported risk of up to 27% to 63% for *BRCA2* and *BRCA1* mutation carriers, respectively. The risk for ovarian cancer within 10 yr of a breast cancer diagnosis is 6.8% (*BRCA2*) to 12.7% (*BRCA1*) as opposed to a general-population risk of less than 1.0%.
  4. Men with HBOC have an up to tenfold increased risk for breast cancer and a more than twofold increase in prostate cancer in comparison to the general-population risk. In men, the *BRCA2* mutation increases the cancer risk more than the *BRCA1* mutation. In fact, the breast cancer risk for a male with a *BRCA2* mutation is up to 80 times the risk seen in the general population.
  5. Both men and women have an elevated risk (up to sevenfold) for pancreatic cancer (*BRCA2* >1) and for melanoma (2.5-fold increase with *BRCA2*).
  6. Ashkenazi Jewish ancestry is associated with founder mutations 187delAG (*BRCA1*), 5382insC (*BRCA1*), and 6174delT (*BRCA2*), which confer a significantly elevated risk for breast and ovarian cancer. As opposed to the 1 in 400 risk in the general population, 1 in 40 individuals of Ashkenazi Jewish descent have a *BRCA 1* or *2* mutation.

Lynch Syndrome (Hereditary Nonpolyposis Colorectal Cancer):

- Individuals with *MLH1, MSH2, MSH6, PMS2, EPCAM* mutations.
- By age 70, Lynch syndrome carriers have—in addition to an increased risk for colorectal, gastric, hepatobiliary, urinary tract, small bowel, brain, skin, and pancreatic cancers—up to an approximately twentyfold increase in ovarian cancer (4% to 12% risk vs. the general-population risk of 0.7%) and up to an approximately fortyfold increase in uterine cancer (25% to 60+% risk vs. the general-population risk of 1.6%).
- The previously listed genes and others (e.g., *PTEN, TP53, CDH1, STK11*) that are found less frequently are considered high-penetrance genes, as they can increase the relative risk of their respective syndromes by greater than four- to fivefold.
- Other, more moderate-penetrant genes (e.g., *CHEK2, ATM, PALB2, BRIP1, RAD51C, RAD51D*), that is, those that are associated with a two- to fourfold increase in the relative risk of cancer, should be considered when assessing risk and ordering genetic tests.

TABLE 2 Genes Associated with Hereditary Ovarian Cancer Predisposition

Gene	Syndrome	Relative Risk of OC	OC Risk by Age 80 Yr	Associated Cancers
High Penetrance				
BRCA1	Hereditary breast ovarian cancer syndrome	~50	~40%	Breast, other
BRCA2	Hereditary breast ovarian cancer syndrome	~8	11%-26%	Breast, pancreas, prostate, other
MLH1 *MSH2* *MSH6* *PMS2* *EPCAM*	Lynch syndrome	~4	~20%	Colon Uterine Stomach Small intestine Urinary tract Pancreatic Possible other sites
Lower or Moderate Penetrance				
RAD51C	None	~5	~6%	Undefined Autosomal recessive Fanconi anemia
RAD51D	None	~12	~14%	Undefined Autosomal recessive Fanconi anemia

OC, Ovarian cancer.

TABLE 3 Testing Criteria for Breast Ovarian Cancer Syndrome*

Individual from a family with a known deleterious *BRCA1* or *BRCA2* gene mutation
Personal history of breast cancer plus one or more of the following:
- Diagnosed at ≤45 yr of age
- Diagnosed at ≤50 yr of age with
  - An additional breast cancer primary
  - At least one close blood relative with breast cancer at any age
  - At least one close relative with pancreatic cancer
  - At least one close relative with prostate cancer
  - An unknown or limited family history
- Diagnosed at age 60 with
  - Triple-negative breast cancer
- Diagnosed at any age with
  - At least one close blood relative with breast cancer before 50 yr of age
  - At least two close blood relatives with breast cancer at any age
  - At least one close blood relative with ovarian cancer
  - At least one close blood relative with pancreatic cancer
  - At least two close blood relatives with prostate cancer
  - A close female blood relative with ovarian cancer
  - An individual of ethnicity associated with a higher mutation frequency
- Personal history of ovarian cancer
- Personal history of male breast cancer
- Personal history of prostate cancer at any age with a close relative with breast, ovarian, or pancreatic cancer at any age
- Personal history of pancreatic cancer and Ashkenazi Jewish ancestry
- Family history meeting any of the above criteria

See NCCN guidelines for the most up-to-date and detailed description for counseling and testing.

*For more detailed information, see the National Comprehensive Cancer Network (NCCN) guidelines.
From Disaia PJ et al: *Clinical gynecologic oncology,* ed 9, Philadelphia, 2017, Elsevier.

TABLE 4 National Comprehensive Cancer Network (NCCN) Guidelines for Recommending Genetic Testing for *BRCA1* or *BRCA2* Mutations*

Personal history of breast cancer and one or more of the following:
- Diagnosed at age ≤45 yr
- Diagnosed with at least two breast cancer primaries (bilateral, separate ipsilateral), the first at age 50 yr
- Diagnosed at age ≤50 yr with one or more close relatives† with breast cancer (prostate or pancreatic) at any age
- Diagnosed with triple-negative breast cancer at age ≤60 yr
- Diagnosed at any age with one or more close relatives with breast cancer at age ≤50 yr
- Diagnosed at any age with two or more close relatives at any age
- Diagnosed at any age with one or more close relatives with invasive ovarian cancer (including fallopian tube and primary peritoneal) at any age
- Diagnosed at any age with two or more close relatives with pancreatic and/or prostate cancer
- Having a close male relative with breast cancer at any age

*Individuals with a limited or unknown family history may have an underestimated probability of a familial gene mutation detection.
†Close relative pertains to first-, second-, or third-degree blood relatives on the same side (either maternal or paternal) of the family.
From Disaia PJ et al: *Clinical gynecologic oncology,* ed 9, Philadelphia, 2017, Elsevier.

- More than 12 known gene mutations are associated with an elevated risk for breast cancer, and a similar number are associated with an elevated risk for ovarian cancer. As such, screening for *BRCA1, BRCA2* alone will miss these mutations.
- In addition to established deleterious mismatch repair gene mutations, gene alterations that are categorized in the literature as emerging risk mutations are also associated with hereditary gynecologic and other cancers.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Present at a younger age
- Bilaterality more likely
- Multiple primaries in one individual

ETIOLOGY

Hereditary cancers are typically due to a genetic mutation in a tumor suppression gene that interferes with DNA repair and allows an otherwise potentially avoidable cancer to develop. This is distinct from familial cancers in which there is no isolated gene mutation but, nonetheless, cancers appear in the family to a degree more than that which would be statistically seen in the general population. Nongenetic factors such as lifestyle habits and environmental influences contribute to cancer risk as well.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- General (sporadic) population or familial basis for the cancer in question.
- Hereditary cancer is more likely to present at a younger age, to span a number of generations, to affect more family members than would be expected (if a large enough family), especially in a suspicious pattern, and to include some rare (ovary, male breast cancer, for example) presentations.
- In addition to the more common syndromes listed previously, consider Cowden *(PTEN),* Peutz-Jeghers *(STK11),* Li-Fraumeni *(TP53),* and others.

WORKUP

Family history questionnaire, patient and family interviews, genetic counseling/risk assessment (including tools such as Tyrer-Cuzick/Gail/Claus models), and tailored genetic testing.

LABORATORY TESTS

- A simple blood or saliva sample drawn in the office or a lab, after informed consent, is needed. This specimen should be sent to a reliable laboratory recognized nationally for its genetic cancer testing accuracy (technologic and interpretative), reporting format, and the support staff ability and availability for consultation, office counseling, and testing integration. Look for a laboratory that has published peer-reviewed data and has an accurate classification methodology that relies on an extensive database. Realize that these labs are not FDA approved and that CLIA certification, while needed, relies on just in-house data. Remember also that most patients get tested only once in their lifetime, and so accuracy is imperative.
- Options include:
  1. Syndrome specific: For example, HBOC-*BRCA* testing (including large rearrangement detection); Lynch syndrome; founder mutation testing (187delAG, 5382insC, 6174delT)—Ashkenazi Jewish population (often recommended as the first test for this population); single-site testing (if a previously identified gene mutation is known in the family); cancer specific, for example, breast cancer panel—*BRCA 1, 2* with/without reflex to broader panel (i.e., sequential testing).
  2. Comprehensive panel testing (can include HBOC syndrome *BRCA1*, *BRCA2*), Lynch syndrome (*MLH1, MSH2, MSH6, PMS2, EPCAM*), Li-Fraumeni (*TP53*), Cowden (*PTEN*), Peutz-Jeghers (*STK11*), *PALB2, CHEK2, ATM, BRIP1, RAD51C*, and others [upward of 28+ genes]).
- Choice of the test is generally based on personal/family history, although thoroughness of the risk assessment may be limited by

attempting to choose a gene test based on history/phenotype alone.
- Comprehensive panel testing has been shown to increase mutation detection and to aid in test selection when patients qualify for more than one syndrome/cancer-specific test, or it can be used to capture a potentially broader view of risk. There is a concern, however, for detecting mutations that are not clinically actionable, at this time.
- Categories of results include (1) positive or negative for a deleterious mutation or (2) a genetic variant of uncertain significance, in which a cancer risk is not yet established or ruled out. It is critical that the classification of these variants is accurate.

IMAGING STUDIES

Screening transvaginal ultrasonography, annual mammography, annual MRI (when breast cancer risk is 20% or more based on Tyrer-Cuzick or other breast cancer risk screening models)

Rx TREATMENT/RISK REDUCTION

- Heightened surveillance, judicious chemoprevention, and prophylactic surgery have been associated with improved outcomes.
- Surveillance includes patient breast awareness, clinical breast exam, mammography, MRI, transvaginal ultrasonography, and CA-125 blood testing, for example.
- Chemopreventive approaches have been shown to reduce the risk of ovarian cancer by up to 60% (with an oral contraceptive) and risk of contralateral breast cancer by as much as 53% (with tamoxifen).
- In HBOC patients, prophylactic total mastectomy can reduce the risk for breast cancer by 90%, and a bilateral salpingo-oophorectomy, after childbearing or by age 40, can reduce the risk of ovarian cancer by up to 96% and the risk of breast cancer by up to 68%.
- Consider preimplantation genetic diagnosis in conjunction with in vitro fertilization.

REFERRAL

If services are needed beyond one's practice or comfort level, consider consulting with knowledgeable genetic counselors, gynecologists, gynecologic oncologists, breast surgeons, and gastroenterology specialists, among others.

! PEARLS & CONSIDERATIONS

- Be vigilant. Be motivated by the risks: Women with these mutations are approximately 10 times more likely to develop breast cancer and 20 to 30 times more likely to develop ovarian cancer. Look for red flags during every encounter, regardless of the patient's chief complaint or scheduled visit type, and inquire and regularly update information about the patient's personal and family history of cancer. Consider that approximately 10% of general practice patients have a significant family history. Supply a printed family history questionnaire. Always consider your patient's cancer risk, especially when charting a new treatment course or planning a surgical procedure. Oftentimes, a more comprehensive approach may be taken if a patient proves to be a mutation carrier.
- Adjust the age at which screening/treatment is initiated and the frequency of the visits depending on the age of the youngest affected family member, the at-risk cancer site, and the carrier status of the patient.
- Encourage input from the patient during the screening, workup, follow-up, and treatment.
- Recommend that the patient verify any questionable family history, collect appropriate family documentation/testing, and involve her family in the process; this involvement can include advising, counseling, and testing for close relatives.
- Try to counsel and test (if appropriate) those family member(s) who, if tested, would render testing of progeny/other family members less necessary. Testing an affected family member is oftentimes the most appropriate, efficient, cost-effective, and informative approach.
- Genetic testing can more accurately predict risk and enable a more tailored management approach than relying on one's family history alone. Be mindful that there may be other, although as yet unidentified, mutations at the root of one's patient's personal or family cancer history.
- Refer to your professional societies and the NCCN for screening and surveillance/imaging/treatment guidelines. Don't hesitate to engage the assistance of a genetic counselor, gynecologist, oncologist, breast surgeon, and/or a gastroenterologist during this initial phase.
- Involve other appropriate specialists in the patient's short- and long-term care, depending on the at-risk anatomic systems.
- Remember that *BRCA1*- and *BRCA2*-positive men are at a significantly higher risk for breast and prostate cancer.
- Consider prophylactic bilateral mastectomy or bilateral salpingo-oophorectomy.
- Encourage high-risk patients to complete childbearing at a younger age and consider, as appropriate, subsequent prophylactic bilateral salpingo-oophorectomy and menopause hormone therapy options.
- Recommend prophylactic bilateral salpingectomy for at-risk patients during any other surgical procedure—once childbearing is complete. Consider such assistive reproductive options as preimplantation genetic diagnosis.
- Genetic information cannot be used as the basis for a "preexisting condition" with regard to health insurance or employment, according to federal and state laws. It may play a role in life insurance, disability insurance, and long-term care insurance.
- While insurance coverage generally is available, panel testing reimbursement may occasionally be challenged. Vocalize and document your support of the appropriate testing and management, with both your patient and her/his insurance company. Enlist the assistance of your local professional society, as needed.
- There may be a medical-legal risk if a failure to identify and/or genetically counsel or test a high-risk patient and/or her family results in a delay in the diagnosis of breast or ovarian cancer. The provider, laboratory, insurance company, and the employer may have legal exposure for failing to order testing, for providing inaccurate results, or for denial of coverage, respectively.
- Being aware of a patient's cancer risk facilitates initiation of those preventive screenings and management strategies that have been shown to reduce the likelihood of cancer and improve early cancer detection rates. This can be of tremendous benefit for the patient's family members as well as the patient.

PREVENTION

Consider appropriate screening and surveillance (awareness/physical exam by patient and health care provider, imaging studies, diagnostic procedures, counseling, and genetic testing) as well as prophylactic surgery and chemopreventive measures.

PATIENT & FAMILY EDUCATION

Always encourage patients to revisit their personal and family history and to update this information with all of their health care providers and their family members. Recommend that patients initiate discussions with their family members and other health care providers in an ongoing effort to reduce their and their loved ones' risk of heritable cancer.

Refer to NCCN guidelines (www.nccn.org) and national specialty society recommendations.

Hereditary Hemorrhagic Telengiectasia

BASIC INFORMATION

DEFINITION

Hereditary hemorrhagic telangiectasia (HHT), also known as Osler-Rendu-Weber syndrome, is a hereditary vascular disorder characterized by the development of arteriovenous malformations throughout the body.

SYNONYMS

Osler-Rendu-Weber syndrome
HHT
Osler disease

ICD-10CM CODE
I78.0 Hereditary hemorrhagic telangiectasia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 1 in 8,000 to 16,500
PREVALENCE: Approximately 1.2 million people worldwide
PREDOMINANT SEX AND AGE:
- Men = women
- Individual variability

GENETICS: Inherited dominant mutation. Mutations in the endoglin gene, a cell surface component of the transforming growth factor–β (TGF-β) receptor complex, causes this syndrome.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Recurrent epistaxis and gastrointestinal (GI) bleeds due to lesions in the oropharyngeal epithelium and gut. The most common manifestation is recurrent and spontaneous epistaxis occurring in 90% to 95% of patients due to fragile telangiectasia on the nasal mucosa.
- 40% to 50% of patients develop GI bleeding sometime during the course of their disease.
- Telangiectasia lesions may be present on the lips, tongue (Fig. E1), nasal mucosa, retina, hands, chest, and lower extremities. There may be many erythematous macules and papules.
- Telangiectasias either are round and mildly raised or are stellate without a well-defined border.
- Mucocutaneous lesions are 1 to 4 mm, sharply demarcated red to purple macules, or spiderlike projections. They usually develop at puberty.

FIG. E1 Hereditary hemorrhagic telangiectasia. (From James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, Elsevier.)

- Arteriovenous (AV) malformations of the lungs, central nervous system, or liver.
- Multiple AV malformations causing liver involvement or atypical cirrhosis are rare but can occur. Liver left-to-right shunting can predispose patients to high-output heart failure.

ETIOLOGY

- Autosomal dominant disorder with incomplete penetrance.
- Mutations in *ENG* and *ACVRLK1* that code for endoglin and ALK, which are TGF-β receptors that function in integrity of vessel structures.
- Type 1 (HHT_1) is due to loss of function gene mutation of *ENG* (9q3).
- Type 2 (HHT_2) is due to loss of function gene mutation of *ALK1* (12q13).
- There is a third type of HHT associated with juvenile polyposis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Generalized essential telangiectasia
- Unilateral nevoid telangiectasia
- Scleroderma with CREST syndrome
- Rosacea
- Actinic keratosis
- Ataxia telangiectasia
- Venous hypertension
- Cushing syndrome

WORKUP

Diagnosis can generally be made from a detailed history and physical exam if at least three of these four criteria are present:
1. Spontaneous recurrent epistaxis
2. Multiple telangiectasias (in multiple sites such as face, mouth, and lips)
3. Visceral lesions such as arteriovenous malformations (AVMs) may result in GI bleeding or hepatic, pulmonary, cerebral, or spinal hemorrhage
4. First-degree relative with diagnosed HHT

If two criteria are present, there is a possible diagnosis.

LABORATORY TESTS

- Complete blood cell count (CBC), including platelet count, to evaluate anemia and rule out thrombocytopenia; coagulation profile. Patients with this disorder have normal levels of clotting factors and an intact clotting mechanism
- Ferritin level, stool for occult blood
- Endoscopy (upper and lower), angiography

IMAGING STUDIES

- Electron microscopy shows lack of pericytes.
- Chest radiograph.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Laser ablation of symptomatic lesions
- GI bleeding prophylaxis
- Angiographic embolization
- Segmental bowel resection
- Surgical correction of AV malformations
- Dermoplasty of the bleeding nasal septum

ACUTE GENERAL Rx

- Optimal therapy remains elusive. Trials comparing topical intranasal treatment with bevacizumab vs. estriol vs tranexamic acid vs. nasal saline spray showed that there was no advantage to topical therapy with these medications compared with frequent saline sprays for reducing the frequency of epistaxis in patients with HHT.
- In those without a history of pulmonary AV malformations, tamoxifen 20 mg/day (antiestrogen) or aminocaproic acid (antifibrinolytic) therapies may be considered.
- In severe cases may consider use of agents such as thalidomide or lenalidomide to block VEGF (high VEGF levels lead to disorganized and tortuous vessels).
- Trials suggest some potential use of phosphoinositide 3-kinase inhibitor BKM120.

CHRONIC Rx

Iron replacement for anemia due to blood loss

DISPOSITION

Prognosis depends on areas affected by AV malformations.

REFERRAL

To ENT and vascular surgeon for correction of vascular malformations, gastroenterologist for esophagogastroduodenoscopy

PEARLS & CONSIDERATIONS

- Primary manifestations usually occur before puberty and are characterized as epistaxis. Later, hemorrhages of GI and genitourinary (GU) tracts occur.
- Vascular abnormalities may result in portal hypertension, pulmonary AV malformations with hemoptysis, cerebrovascular accidents, and hematuria in addition to GI bleeding and anemia.
- Genetic screening of first-degree relatives should be performed.
- 5% to 10% of patients have pulmonary AV malformations.
- In two thirds of individuals who have neurologic symptoms, the source is pulmonary AV malformations.
- Those with history of pulmonary AV malformations require antibacterial prophylaxis for surgical or dental operations.
- Approximately 15% to 20% of patients with AV malformations in the lungs present with stroke due to embolic abscesses.

COMMENTS

Affected children may experience recurrent epistaxis before detection of the characteristic skin and mucous membrane lesions.

PREVENTION

Seek genetic counseling if one has a family history of Osler-Rendu-Weber syndrome.

Herpangina PTG

BASIC INFORMATION

DEFINITION

Herpangina is a self-limited upper respiratory tract infection associated with a characteristic vesicular rash on the soft palate.

SYNONYMS

Vesicular stomatitis
Acute lymphonodular pharyngitis

ICD-10CM CODE
B08.5 Enteroviral vesicular pharyngitis

EPIDEMIOLOGY & DEMOGRAPHICS

PREDOMINANT SEX: Male = female
PREDOMINANT AGE: 3 to 10 yr

PHYSICAL FINDINGS & CLINICIAL PRESENTATION

- Characterized by ulcerating lesions typically located on the soft palate (Fig. E1)
- Usually fewer than six lesions that evolve rapidly from a diffuse pharyngitis to erythematous macules and subsequently to vesicles that are moderately painful
- Fever, vomiting, and headache in the first few days of illness but subsiding spontaneously
- Pharyngeal lesions typical for several more days

ETIOLOGY

- Most cases caused by coxsackie A viruses (most frequently A8, A10, and A16).
- Occasional cases caused by other enteroviruses (echovirus and enterovirus 71).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Herpes simplex
- Bacterial pharyngitis
- Tonsillitis
- Aphthous stomatitis
- Hand-foot-mouth disease

WORKUP

Diagnosis is typically based on characteristic lesions on the soft palate.

LABORATORY TESTS

- Viral and bacterial cultures of the pharynx to exclude herpes simplex infection and streptococcal pharyngitis if the diagnosis is in doubt.
- The type-specific antibodies appear in the blood about 1 wk after infection has occurred and attain their maximum titer in 3 wk.

FIG. E1 Herpangina with shallow ulcers in the roof of the mouth. (From Bennett JE et al [eds]: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Elsevier.)

TREATMENT

- Give symptomatic treatment for sore throat: Saline gargles and analgesics, and encourage oral fluids.
- No antiviral therapy indicated; avoid antibacterial agents because they are ineffective, increase cost, might result in side effects, and promote antibiotic resistance.

NONPHARMACOLOGIC THERAPY

Analgesic throat lozenges are helpful in some cases.

ACUTE GENERAL Rx

Antipyretics when indicated

CHRONIC Rx

Self-limited infection

DISPOSITION

- Generally, resolution of symptoms within 1 wk
- Persistence of fever or mouth lesions beyond 1 wk suggestive of an alternative diagnosis (see "Differential Diagnosis")

REFERRAL

For consultation with otolaryngologist or infectious disease specialist if the diagnosis is in doubt.

PEARLS & CONSIDERATIONS

COMMENTS

Household outbreaks may occur, especially during the summer months.

Herpangina (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

Herpes simplex is a viral infection caused by the herpes simplex virus (HSV). HSV-1 is associated primarily with oral infections, and HSV-2 causes mainly genital infections. However, either type can infect any site. After the primary infection, the virus enters the nerve endings in the skin directly below the lesions and ascends to the dorsal root ganglia, where it remains in a latent stage until it is reactivated.

SYNONYMS

Genital herpes
Herpes labialis
Herpes gladiatorum
Herpes digitalis
Oral herpes

ICD-10CM CODES	
A60	Anogenital herpesviral (herpes simplex) infections
A60.04	Herpesviral vulvovaginitis
B00	Herpesviral (herpes simplex) infections
B00.1	Herpesviral vesicular dermatitis
B00.82	Herpes simplex myelitis
B00.9	Herpesviral infection, unspecified
P35.2	Congenital herpesviral (herpes simplex) infection

EPIDEMIOLOGY & DEMOGRAPHICS

- More than 85% of adults have serologic evidence of HSV-1 infection. The seroprevalence of adults with HSV-2 in the U.S. is 25%; however, only approximately 20% of these persons recall having symptoms of HSV infection.
- Most cases of eye or digital herpetic infections are caused by HSV-1.
- Worldwide, more than 400 million persons have genital herpes caused by HSV-2. In the U.S., 1 in 5 adults is infected with HSV-2, and 1 million new infections occur yearly.
- Frequency of recurrence of HSV-2 genital herpes is higher than HSV-1 oral labial infection.
- The frequency of recurrence is lowest for oral labial HSV-2 infections.
- The incidence of complications from herpes simplex (e.g., herpes encephalitis) is highest in immunocompromised hosts.
- Male circumcision significantly reduces the incidence of HSV-2.

PHYSICAL FINDINGS & CLINICIAL PRESENTATION

PRIMARY INFECTION:

- Symptoms occur from 3 to 7 days after contact (respiratory droplets, direct contact).
- Constitutional symptoms include low-grade fever, headache and myalgias, regional lymphadenopathy, and localized pain.
- Pain, burning, itching, and tingling last several hours.
- Grouped vesicles, usually with surrounding erythema, appear and generally ulcerate or crust within 48 h (Fig. E1).
- The vesicles are uniform in size (differentiating it from herpes zoster vesicles, which vary in size). Scattered erosions covered with exudate may be noted on genitals (Fig. E2).
- During the acute eruption the patient is uncomfortable; involvement of lips and inside of mouth (Fig. E3) may make it unpleasant for the patient to eat; urinary retention may complicate involvement of the genital area.
- Lesions generally last from 2 to 6 wk and heal without scarring.

RECURRENT INFECTION:

- Generally caused by alteration in the immune system; fatigue, stress, menses, local skin trauma, and exposure to sunlight are contributing factors.
- The prodromal symptoms (fatigue, burning and tingling of the affected area) last 12 to 24 hr.
- A cluster of lesions generally evolves within 24 hr from a macule to a papule and then vesicles surrounded by erythema; the vesicles coalesce and subsequently rupture within 4 days, revealing erosions covered by crusts.
- The crusts are generally shed within 7 to 10 days, revealing a pink surface.
- The most frequent location of the lesions is on the vermilion border of the lips (HSV-1), the penile shaft or glans penis and the labia (HSV-2), buttocks (seen more frequently in women), fingertips (herpetic whitlow), and trunk (may be confused with herpes zoster).
- Rapid onset of diffuse cutaneous herpes simplex (eczema herpeticum) may occur in certain atopic infants and adults. It is a medical emergency, especially in young infants, and should be promptly treated with acyclovir.
- Herpes encephalitis, meningitis, and ocular herpes can occur in patients with immunocompromised status and occasionally in normal hosts.

ETIOLOGY

HSV-1 and HSV-2 are both DNA viruses.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Impetigo
- Behçet syndrome
- Coxsackie virus infection
- Syphilis
- Stevens-Johnson syndrome
- Herpangina
- Aphthous stomatitis
- Varicella
- Herpes zoster

WORKUP

Diagnosis is based on clinical presentation. Laboratory evaluation confirms diagnosis.

LABORATORY TESTS

- Direct immunofluorescent antibody slide tests provide a rapid diagnosis.
- Viral culture is the most definitive method for diagnosis; results are generally available in 1 or 2 days. The lesions should be sampled during the vesicular or early ulcerative stage; cervical samples should be taken from the endocervix with a swab.
- Pap smear will detect HSV-infected cells in cervical tissue from women without symptoms.
- Serologic tests for HSV: Immunoglobulin (Ig) G and IgM serum antibodies. Antibodies to HSV occur in 50% to 90% of adults. The presence of IgM or a fourfold or greater rise in IgG titers indicates a recent infection (convalescent sample should be drawn 2 to 3 wk after the acute specimen is drawn).
- Tzanck smear is a readily available test that will demonstrate multinucleated giant cells. However, it is not a highly sensitive test.

TREATMENT

- Table 1 summarizes antiviral chemotherapy for HSV infection.
- Topical acyclovir, penciclovir, and docosanol are optional treatments for recurrent herpes labialis, but they are less effective than oral treatments.

DISPOSITION

Most patients recover from the initial episode or recurrences without complications; immunocompromised hosts are at risk for complications (e.g., disseminated herpes simplex infection, herpes encephalitis).

REFERRAL

- Hospital admission in patients with herpes encephalitis or herpes meningitis and in immunocompromised hosts with diffuse herpes simplex infection
- Ophthalmology referral in patients with suspected ocular herpes

PEARLS & CONSIDERATIONS

COMMENTS

- Provide patient education regarding transmission of HSV.
- Condom use offers significant protection against HSV-1 infection in susceptible women.
- Patients should be instructed on the use of condoms for sexual intercourse and on avoiding kissing or sexual intercourse until lesions are crusted. Pericoital application of tenofovir gel, an antiretroviral vaginal gel, has also been shown to reduce the risk of HSV-2 in women. This may be useful in regions of the world where use of condoms is shunned.
- Patients should also avoid contact with immunocompromised hosts or neonates while lesions are present.

TABLE 1 Topical and Oral Antiviral Medications Used for Herpes Simplex Virus Infections*

Drug	Formulation	Regimen	Indication/Comment
Topical			
Acyclovir	5% cream (2 g, 5 g)	Apply 5 times/day	Recurrent HL; A: ≥12 yr; 4 days; Rx
	5% ointment (15 g, 30 g)	Apply 6 times/day	Initial GH, localized HSV; A: adults; 7 days; Rx
Penciclovir	1% cream (1.5 g, 5 g)	Apply q2h (awake)	Recurrent HL; A: ≥12 yr; 4 days; Rx
Docosanol	10% cream (2 g)	Apply 5 times/day	HL; A: ≥12 yr; treat until healed; OTC
Oral (all Rx)			
Acyclovir	200 mg capsule		A: ≥2 yr
	400 mg, 800 mg tablet		
	200 mg/5 ml susp		
		200 mg 5 times/day	Initial GH; 10 days
		200 mg 5 times/day	Recurrent GH; 5 days
		400 mg 2 times/day	Suppression, recurrent GH; up to 12 mo, then reevaluate
Famciclovir	125, 250, 500 mg tablet		A: ≥18 yr
		1500 mg single dose	Recurrent HL
		1000 mg 2 times/day	Recurrent GH; 1 day
		250 mg 2 times/day	Suppression, recurrent GH; up to 12 mo
Valacyclovir	500 mg, 1 g caplet		A: adults and ≥12 yr for HL
		1 g 2 times/day	Initial GH; 10 days
		500 mg 2 times/day	Recurrent GH; 3 days
		500 mg-1 g once daily	Suppressive GH
		2 g 2 times/day	HL; 1 day; both adults and children ≥12 yr

*Approved indications and regimens listed; often used off-label.
A, Approved; *GH,* genital herpes; *HL,* herpes labialis; *HSV,* herpes simplex virus; *OTC,* over-the-counter; *Rx,* by prescription.

- Proper handwashing techniques should be explained.
- Patients with herpes gladiatorum (cutaneous herpes in athletes involved in contact sports) should be excluded from participation in active sports until lesions have resolved.
- Many new HSV-2 infections are asymptomatic. Since HSV-2 antibody tests have become commercially available, an increasing number of persons have learned that they have genital herpes through serologic testing. Persons with asymptomatic HSV-2 infection shed virus in the genital tract less frequently than persons with symptomatic infection, but much of the difference is attributable to less frequent genital lesions because genital lesions are accompanied by frequent viral shedding. The U.S. Preventive Services Task Force (USPSTF) recommends against routine serologic screening for genital HSV infection in asymptomatic adolescents and adults, including those that are pregnant.
- Suppressive treatment of HSV-2 infection lowers the incidence of genital lesions by 70% to 80%, but cuts the rate of HSV-2 transmission to uninfected partners by only 50%.
- Pregnancy: Antiviral prophylaxis with acyclovir is recommended from 36 wk of gestation until delivery in women with a history of genital herpes. Elective cesarean delivery should be performed in laboring patients with active lesions to decrease the risk of neonatal herpes.
- Trials involving investigational herpes simplex vaccine have found it to be effective in preventing HSV-1 genital disease and infection, but not in preventing HSV-2 disease or infection.

BASIC INFORMATION

DEFINITION

Corneal infection with herpes simplex virus (HSV-1 or HSV-2).

SYNONYMS

Herpes simplex keratoconjunctivitis
Herpes simplex dendritic keratitis
Herpes simplex stromal keratitis
Herpetic keratitis

ICD-10CM CODE
B00.52 Herpes viral keratitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 5/100,000 to 15/100,000 per yr
PEAK INCIDENCE: After an episode of ocular HSV, there is a 30% chance of a recurrence within a 1-yr period.
PREVALENCE: 149/100,000 people
PREDOMINANT SEX & AGE: Equal, although some studies report a slight male predominance. There are no known patterns of age of presentation.
GENETICS: There are no known patterns of genetic inheritance.
RISK FACTORS: Risk factors include close physical contact with an HSV disease carrier and primary or latent infection with HSV-1 or HSV-2. Neonatal ocular HSV can result from direct maternal transmission. The landmark Herpetic Eye Disease Study (HEDS) found that prior stromal keratitis increases the chances of recurrent stromal keratitis, but prior epithelial keratitis does not increase the chance of recurrent epithelial keratitis. That study also found that proposed triggers of recurrent disease, including psychological stress, systemic infection, sunlight exposure, menstruation, contact lens wear, and eye injury, are not associated with an increased recurrence rate.

PHYSICAL FINDINGS & CLINCIAL PRESENTATION

- Ocular manifestations of HSV infection include periocular vesicular skin lesions, conjunctival injection, follicular conjunctivitis, iridocyclitis, elevated intraocular pressure, and keratitis.
- Patients commonly present with a red eye, ocular pain, tearing, and/or photophobia.
- HSV can affect any part of the cornea and present as epithelial keratitis, stromal keratitis, or endotheliitis. Corneal findings are best visualized using slit-lamp microscopy. Classic dendritic lesions in epithelial keratitis can be seen with a cobalt blue light or a Wood's light following administration of topical fluorescein.
- Presentation is usually unilateral and may occur in the setting of a concurrent upper respiratory infection or other systemic conditions. Recurrent HSV infections may occur in a patient with a history of prior "eye infections."

ETIOLOGY

HSV keratitis results from HSV-1 or (less commonly) HSV-2 infection of the cornea and the subsequent host immune and inflammatory response. HSV keratitis most often represents reactivation of a latent infection in the trigeminal ganglion. Primary infection is rarely clinically evident.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Herpes zoster ophthalmicus, corneal abrasion, recurrent corneal erosion, viral conjunctivitis, allergic conjunctivitis, acanthamoeba keratitis

WORKUP

Ocular HSV disease is most often a clinical diagnosis, although diagnosis may be aided by cytologic, molecular, and immunologic assays described in the following.

LABORATORY TESTS

Culture of corneal or vesicular skin lesion scrapings or cytologic examination with Giemsa stain. PCR and a variety of immunologic assays can also aid with diagnosis but are of limited availability. Serologic antibody testing can help exclude HSV as a diagnosis with a negative result, but positive results are of limited value given the high seroprevalence of HSV.

TREATMENT

The treatment of ocular herpetic disease is determined by the location and extent of disease involvement, with several recommendations resulting from the HEDS study. Oral antivirals and topical antivirals are the mainstay of treatment. Topical antivirals are typically reserved for epithelial keratitis. Oral antivirals are preferred for stromal and endothelial disease. Topical antibiotics and topical corticosteroids are also used in select cases.

NONPHARMACOLOGIC THERAPY

- Corneal epithelial involvement may benefit from the addition of epithelial debridement, and nonhealing epithelial defects may be addressed with bandage contact lenses or tarsorrhaphy.
- After resolution of keratitis, corneal stromal scars may be managed surgically with partial-thickness (i.e., deep anterior lamellar keratoplasty) or full-thickness penetrating keratoplasty (corneal transplantation).

ACUTE GENERAL Rx

- Systemic antiviral treatment options: Acyclovir 400 mg PO five times daily, valacyclovir 500 mg PO bid, famciclovir 125 to 250 mg PO bid for 7 to 14 days
- Eyelid involvement only: Systemic antiviral, antibiotic ointment bid, and warm or cool compresses PRN for comfort
- Eyelid margin, corneal epithelial, and/or conjunctival involvement: Systemic antiviral or topical antiviral (ganciclovir 0.15% gel, trifluridine 1% drops) five times daily, topical antibiotic qid (i.e., fourth-generation fluoroquinolone)
- Corneal stromal involvement: Systemic antiviral, topical steroid (i.e., prednisolone acetate 1% qid), cycloplegic (i.e., cyclopentolate 1% bid)
- Iridocyclitis/trabeculitis: Systemic antiviral, topical steroids with or without systemic steroids

CHRONIC Rx

- When used, topical antivirals are typically continued for 1 to 2 wk until the epithelial defect is healed.
- Topical steroids for corneal stromal involvement are tapered slowly over wks to mos.
- Prophylactic oral antivirals (acyclovir 400 mg or famciclovir 125 mg PO bid) may be used indefinitely for severe cases and have been shown to reduce the rate of recurrences.

DISPOSITION

Patients with ocular HSV require referral and close follow-up with ophthalmology, initially every 1 to 2 days, with extended follow-up based on clinical course.

REFERRAL

A patient with suspected ocular herpetic disease should be started on systemic antivirals and then referred promptly for evaluation by an ophthalmologist.

PEARLS & CONSIDERATIONS

COMMENTS

Herpes simplex is one of the most common causes of corneal blindness. Physicians from all specialties should be aware of the high seroprevalence of the herpes simplex virus and maintain a high index of suspicion for ocular herpetic disease when patients with or without a known history of herpes simplex present with ocular complaints such as red eye, ocular pain, and photophobia. Treatment with systemic antiviral medication and prompt referral to an ophthalmologist are crucial early steps in the management of suspected disease.

PREVENTION

Despite significant interest, there is currently no HSV vaccine available. Given the high prevalence of HSV in the community, it is difficult to prevent systemic and ocular HSV infection. In

patients who have a history of ocular HSV, there is evidence to support the efficacy of maintenance systemic antiviral medication to prevent disease recurrences.

RELATED CONTENT

Herpes Simplex (Related Key Topic)
Herpes Zoster (Related Key Topic)

AUTHOR: **Thomas H. Dohlman, MD**

SUGGESTED READING

White ML, Chodosh J: Herpes simplex virus keratitis: a treatment guideline 2014, *Ophthalmology* 2014. Available at https://www.aao.org/clinical-statement/herpes-simplex-virus-keratitis-treatment-guideline.

BASIC INFORMATION

DEFINITION

Herpes zoster is a disease caused by reactivation of the varicella-zoster virus, with spread of the virus alone from the sensory nerve to the dermatome. After the primary infection (chickenpox), the virus becomes latent in the dorsal root ganglia and reemerges when there is a weakening of the immune system (as a result of disease or advanced age). Over 90% of the adult U.S. population is latently infected with varicella zoster virus.

SYNONYMS

Shingles
HZ

ICD-10CM CODES

B02	Herpes zoster
B02.0	Zoster encephalitis
B02.1	Zoster meningitis
B02.30	Zoster ocular disease, unspecified
B02.31	Zoster conjunctivitis
B02.32	Zoster iridocyclitis
B02.33	Zoster keratitis
B02.34	Zoster scleritis
B02.39	Other herpes zoster eye disease
B02.7	Disseminated zoster
B02.8	Zoster with other complications
B02.9	Zoster without complications

EPIDEMIOLOGY & DEMOGRAPHICS

- Herpes zoster occurs during the lifetime of 10% to 20% of the population. There are approximately 1 million cases annually in the U.S. The incidence of herpes zoster has increased fourfold over the past six decades.
- There is an increased incidence in immunocompromised patients (chemotherapy, radiotherapy, immunosuppression due to corticosteroids, AIDS, DM, malignancy), the elderly (most common after age 60) (Fig. E1), and children who acquired chickenpox when younger than 2 mo.

PHYSICAL FINDINGS & CLINICIAL PRESENTATION

- Pain generally precedes skin manifestation by 3 to 5 days and is generally localized to the dermatome that will be affected by the skin lesions.
- Constitutional symptoms are often present (malaise, fever, headache).
- The initial rash consists of erythematous maculopapules generally affecting one dermatome (thoracic region in majority of cases [Fig. E2]). Typically the rash does not cross the midline. Some patients (<30%) may have scattered vesicles outside the affected dermatome. In rare cases the rash can be generalized (Fig. E3).
- The initial maculopapules evolve into vesicles and pustules by the third or the fourth day.
- The vesicles have an erythematous base (Fig. E4), are cloudy, of various sizes (a distinguishing characteristic from herpes simplex, in which the vesicles are of uniform size), and may have a classic appearance of grouped vesicles (Fig. E5).
- The vesicles subsequently become umbilicated and then form crusts that generally fall off within 3 wk; scarring may occur.
- Pain during and after the rash is generally significant. Postherpetic neuralgia occurs after herpes zoster in approximately one third of patients aged 60 yr and older and can persist for mos or yrs.
- Secondary bacterial infection with *Staphylococcus aureus* or *Streptococcus pyogenes* may occur.
- Regional lymphadenopathy may occur.
- Herpes zoster may involve the trigeminal nerve (most frequent cranial nerve involved); involvement of the first division of the trigeminal nerve is known as "herpes zoster ophthalmicus" and can result in blindness. The appearance of blisters on the tip of the nose (Hutchinson sign) is a common manifestation of herpes zoster ophthalmicus. Involvement of the geniculate ganglion can cause facial palsy and a painful ear, with the presence of vesicles on the pinna and external auditory canal (Ramsay Hunt syndrome).
- Pain typical of herpes zoster in the absence of cutaneous lesions, known as "Zoster sine herpete," is rare.

ETIOLOGY

Reactivation of varicella virus (human herpes virus III)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Rash: Herpes simplex and other viral infections, contact dermatitis
- Pain from herpes zoster: May be confused with acute myocardial infarction, pulmonary embolism, pleuritis, pericarditis, renal colic

WORKUP

The diagnosis of herpes zoster is usually made by the characteristic dermatomal presentation.

LABORATORY TESTS

Laboratory tests are generally not necessary. In cases where the clinical diagnosis is not obvious, PCR testing for varicella zoster virus is has high sensitivity and specificity. It is readily available and results can usually be obtained in less than 24 hours. Other laboratory studies for diagnosis of herpes zoster include viral culture, DFA, and serologic testing.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Wet compresses (using Burow solution or cool tap water) applied for 15 to 30 min five to ten times a day may be useful to break vesicles and remove serum and crust. Then carefully pat dry.
- Care must be taken to prevent any secondary bacterial infection by keeping cutaneous lesions clean and dry.

ACUTE GENERAL Rx

- Oral antiviral agents can shorten the disease course and help prevent post-herpetic neuralgia. They can decrease acute pain, inflammation, and vesicle formation when treatment is begun within 72 hr of onset of rash. Treatment options are:
  1. Valacyclovir 1000 mg tid for 7 days
  2. Famciclovir 500 mg tid for 7 days
  3. Acyclovir 800 mg 5 times daily for 7 to 10 days
- The role of corticosteroids in herpes zoster is controversial. Many physicians prescribe them to improve rash healing and reduce pain severity; however, a Cochrane review failed to show sufficient evidence to support the use of corticosteroids for the prevention of postherpetic neuralgia. Corticosteroids can be considered in older patients within 72 hr of clinical presentation or if new lesions are still appearing if there are no contraindications to their use. Initial dose is prednisone 60 mg/day decreased by 5 mg/day until finished.
- Immunocompromised patients and patients with herpes zoster complicated by CNS involvement should be treated with IV acyclovir 10 to 15 mg/kg q8h in 1-hr infusions for 7 days, with close monitoring of renal function and adequate hydration; vidarabine (continuous 12-hr infusion of 10 mg/kg/day for 7 days) is also effective for treatment of disseminated herpes zoster in immunocompromised hosts.
- Patients with AIDS and transplant recipients may develop acyclovir-resistant varicella-zoster; these patients can be treated with foscarnet (40 mg/kg IV q8h) continued for at least 10 days or until lesions are completely healed.
- Postherpetic neuralgia:
  1. Gabapentin 100 to 600 mg tid is effective in the treatment of pain and sleep interference associated with postherpetic neuralgia. Other effective agents are pregabalin, duloxetine, and tricyclic antidepressants.
  2. Lidocaine patch 5% is also effective in relieving postherpetic neuralgia. Patches are applied to intact skin after resolution of blisters and crusts to cover the most painful area for up to 12 hr within a 24-hr period.
  3. Capsaicin cream can be useful for treatment of postherpetic neuralgia. It is generally applied 3 to 5 times daily for several weeks after the crusts have fallen off. A topical 8% patch formulation of capsaicin is now available by prescription for postherpetic neuralgia.
  4. Sympathetic blocks (stellate ganglion or epidural) with 0.25% bupivacaine and rhizotomy are reserved for severe cases unresponsive to conservative treatment.

DISPOSITION

- The incidence of postherpetic neuralgia (defined as pain that persists more than 90 days after onset of rash) increases with age (<30% by age 40 yr, >70% by age 70 yr); antivirals reduce the risk of postherpetic neuralgia.
- Incidence of disseminated herpes zoster is increased in immunocompromised hosts (e.g., 15% to 50% of patients with active Hodgkin disease).
- Immunocompromised hosts are also more prone to neurologic complications (encephalitis, myelitis, cranial and peripheral nerve palsies, acute retinal necrosis). The mortality rate is 10% to 20% in immunocompromised hosts with disseminated zoster.
- Motor neuropathies occur in 5% of all cases of zoster; complete recovery occurs in >70% of patients.
- Rates of HZ recurrence are more frequent than previously reported and are comparable to rates of first HZ occurrence in immunocompetent individuals.

REFERRAL

- Hospitalization for IV acyclovir in patients with disseminated herpes zoster.
- Patients with herpes zoster ophthalmicus should be referred to an ophthalmologist.
- Consultation with an otolaryngologist is advisable in patients with Ramsey Hunt syndrome.
- Vaccination: In the absence of the herpes zoster vaccine, persons who live to 85 yr of age have a 50% risk of herpes zoster. Immunocompetent adults ≥50 yr (including those who have already received Zostavax) are appropriate candidates for recombinant varicella zoster virus vaccine (Shingrix). It consists of 2 doses 2 to 6 mo apart and is preferred over Zostavax for herpes zoster prevention. Adults who are VZV seronegative (never had varicella) should be immunized against varicella with two doses of varicella vaccine (Varivax). Despite its efficacy and safety, use of this vaccine remains low (<8% of potential recipients).

Hiatal Hernia (PTG)

BASIC INFORMATION

DEFINITION

Protrusion of a portion of the stomach into the thoracic cavity through the diaphragmatic esophageal hiatus

SYNONYMS

Hiatus hernia
Diaphragmatic hernia

ICD-10CM CODES

K44.9	Diaphragmatic hernia without obstruction or gangrene
Q40.1	Congenital hiatus hernia
Q79.0	Congenital diaphragmatic hernia
K44.0	Diaphragmatic hernia with obstruction, without gangrene
K44.1	Diaphragmatic hernia with gangrene

EPIDEMIOLOGY & DEMOGRAPHICS

- Found in 50% of patients older than 50 yr.
- Prevalence increases with age.
- More prevalent in Western countries than in Africa and Asia.
- Paraesophageal hiatal hernias are more common in women than in men (4:1).
- Associated with diverticulosis (25%), esophagitis (25%), duodenal ulcers (20%), and gallstones (18%).
- Saint triad: Hiatal hernia, diverticular disease, cholelithiasis.
- More than 90% of patients with endoscopic documentation of esophagitis have hiatal hernias.

PHYSICAL FINDINGS & CLINICIAL PRESENTATION

Most patients are asymptomatic. If symptoms are present, they resemble those of gastroesophageal reflux disease (GERD):

- Heartburn
- Dysphagia
- Regurgitation of gastric contents
- Chest pain
- Postprandial fullness
- GI bleed
- Dyspnea
- Hoarseness
- Wheezing with bowel sounds heard over the left lung base

ETIOLOGY

- The repetitive stretching of the gastroesophageal (GE) junction with swallowing and actions (e.g., vomiting, coughing) or states (e.g., obesity, pregnancy) that increase intraabdominal pressure may cause widening of the hiatus, rupture of the phrenoesophageal ligament, and onset of the hernia.
- Hiatal hernias are classified as:
  1. Type I: Sliding (Fig. E1), axial, or concentric hiatal hernia (most common type, 99%). Only the GE junction protrudes into the thoracic cavity, and the phrenoesophageal ligament remains intact.
  2. Type II: Paraesophageal or rolling hernia (Fig. E2) (1%). The GE junction stays at the level of the diaphragm, but part of the stomach bulges into the thoracic cavity through a defect in the phrenoesophageal ligament.
  3. Type III (Fig. E3): Mixed (rare), a combination of type I and type II.
  4. Type IV (Fig. E4): Large defect in hiatus that allows other intraabdominal organs to enter the hernia sac.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Peptic ulcer disease
- Unstable angina
- Esophagitis (caused by *Candida,* herpes, NSAIDs, etc.)
- Esophageal spasm
- Barrett esophagus
- Schatzki ring
- Achalasia
- Zenker diverticulum
- Esophageal cancer

WORKUP

Exclude conditions noted in the differential diagnosis and document the presence of a hiatal hernia. Upper endoscopy may also be needed to exclude abnormal metaplasia, dysplasia, or neoplasia.

LABORATORY TESTS

- Blood tests are not specific.
- Esophageal manometry, although not commonly done, can be used in establishing a diagnosis (low sensitivity, but high specificity when compared with endoscopy).

IMAGING

- Upper gastrointestinal (UGI) barium contrast swallow series: Best defines the anatomic abnormality. Demonstration that the gastric cardia is herniated 2 cm above the hiatus is diagnostic. UGI may also reveal a tortuous

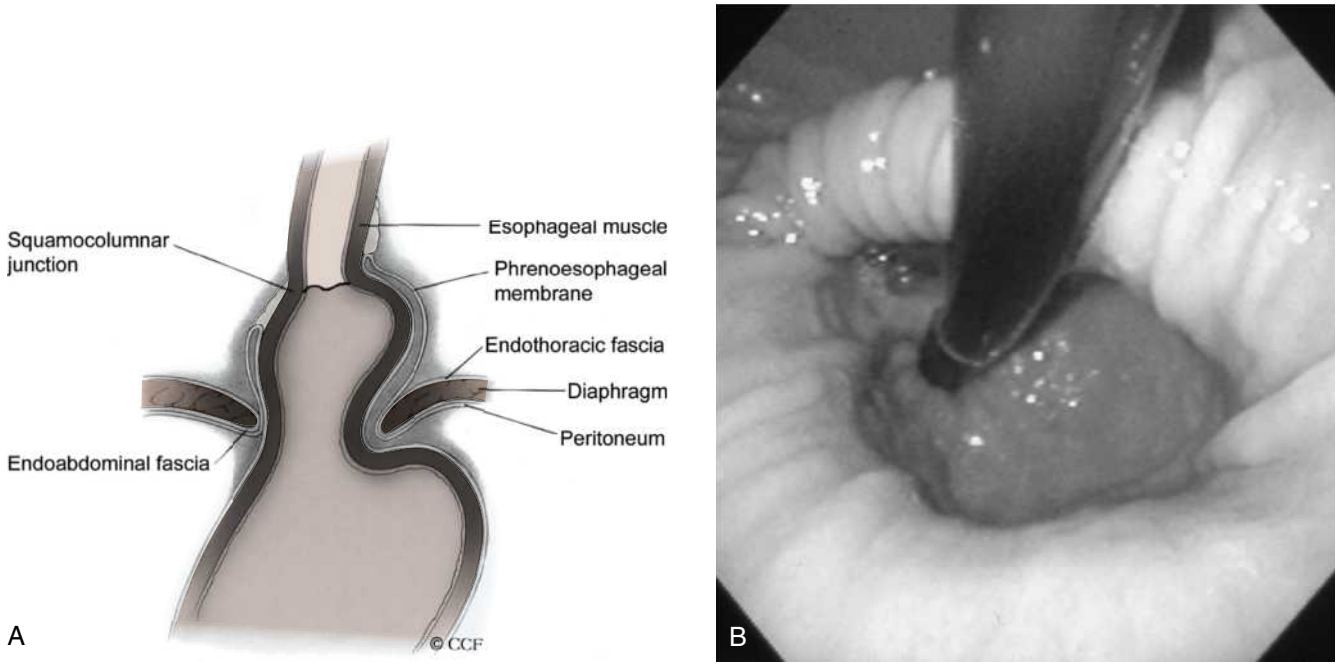

FIG. E1 Type I hiatal hernia. A, Pictorial presentation. **B,** Retroflexed view from the intraabdominal stomach at esophagoscopy. Diaphragmatic impression and intrathoracic stomach can be seen. (From Sellke FW et al: *Sabiston & Spencer surgery of the chest,* ed 9, Philadelphia, 2016, Elsevier.)

esophagus. If endoscopy is performed preoperatively, a barium swallow is generally not necessary.
- UGI endoscopy: Documents the presence of a hiatal hernia and excludes commonly associated findings of esophagitis and Barrett esophagus (recommended at least once during the workup). The >2 cm of gastric rugal fold seen above the margins of the diaphragmatic crura is diagnostic.
- Abdominal ultrasonography: Simple, well tolerated. A transdiaphragmatic esophageal diameter of ≥18 mm is highly suggestive of the presence of a sliding hiatal hernia.
- Computed tomography: Hiatal hernia is often seen as an incidental finding on CT scans done for other reasons.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Lifestyle modifications: Avoid foods and drugs that decrease lower-esophageal pressure (e.g., caffeine, chocolate, mint, calcium channel blockers, and anticholinergics).
- Weight loss, decrease in abdominal circumference.
- Avoid large meals.
- Sleep with the head of the bed elevated 6 inches.

ACUTE GENERAL Rx

- Antacids may be useful to relieve mild symptoms.
- H2 antagonists (e.g., ranitidine 150 mg bid or 300 mg qd, or famotidine 20 mg bid).
- If significant GERD is present with documented esophagitis, proton pump inhibitors (PPIs, e.g., omeprazole 20 mg qd or lansoprazole 30 mg qd) are used. Refractory symptoms may require higher doses (e.g., bid dosing).
- Prokinetic agents (e.g., metoclopramide 10 mg taken 30 min before each meal) can be added to an H2 antagonist or PPI.

CHRONIC Rx

- When indicated, surgery (laparoscopic or open) can be done in patients with refractory symptoms impairing quality of life or causing intestinal (e.g., recurrent GI bleeds) or extraintestinal complications (e.g., aspiration pneumonia, asthma, or ear, nose, and throat complications).
- Prophylactic surgery is a consideration in all paraesophageal hernias because they have a higher incidence of strangulation.

DISPOSITION

- More than 90% of patients with GERD symptoms respond well to medical therapy.
- Complications of hiatal hernias are similar to complications occurring in patients with GERD:
  1. Erosive esophagitis
  2. Ulcerative esophagitis
  3. Barrett esophagus
  4. Peptic stricture
  5. GI hemorrhage
  6. Extraintestinal complications
  7. Lung collapse or heart failure (severe cases)

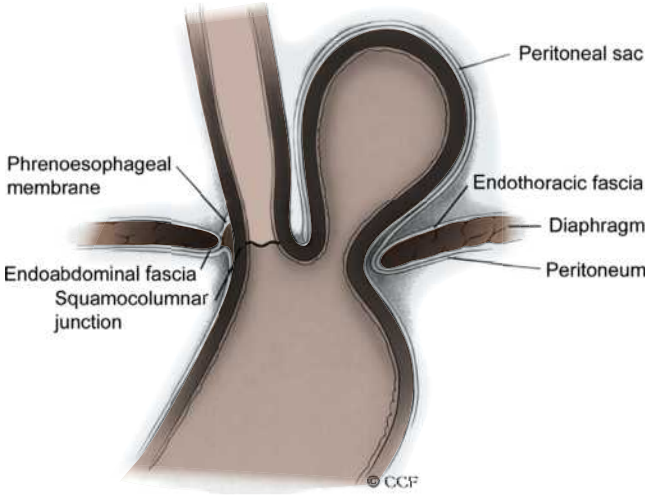

FIG. E2 Type II hiatal hernia. (From Sellke FW et al: *Sabiston & Spencer surgery of the chest,* ed 9, Philadelphia, 2016, Elsevier.)

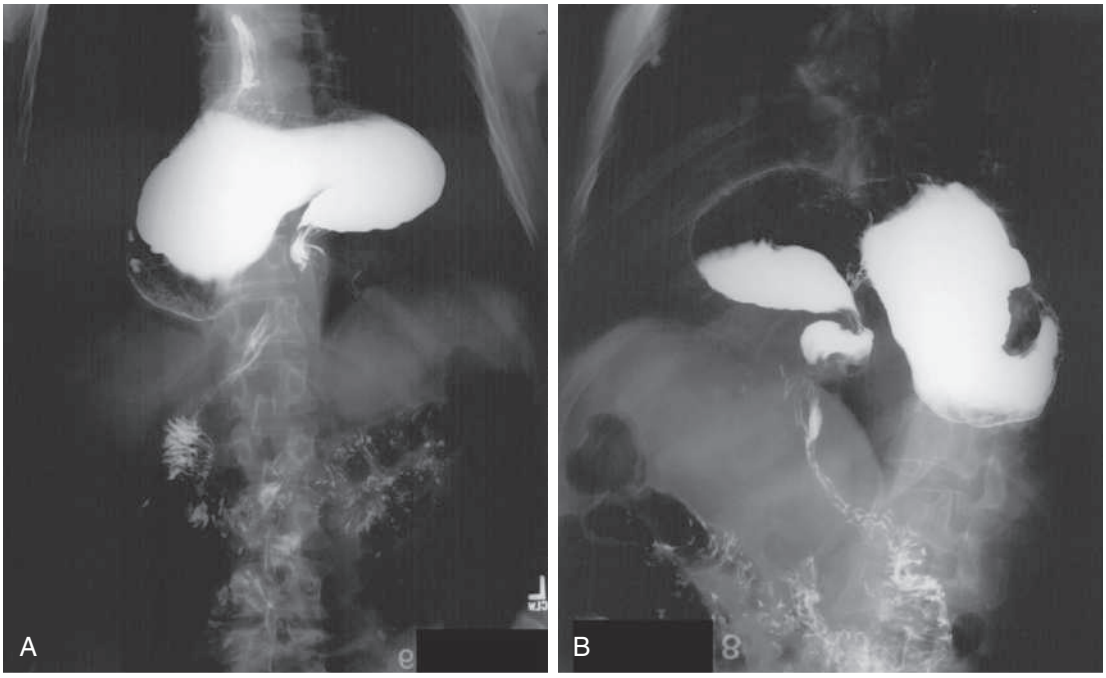

FIG. E3 Type III hiatal hernia. Barium esophagram demonstrates a type III hiatal hernia with organoaxial rotation. **A,** Posteroanterior view. **B,** Lateral view. (From Sellke FW et al: *Sabiston & Spencer surgery of the chest,* ed 9, Philadelphia, 2016, Elsevier.)

REFERRAL

- Gastroenterologist for symptoms refractory to conventional therapy (H_2 antagonists, antacids, and PPIs) or having complications previously mentioned.
  - General surgery evaluation for large hiatal hernia or severe complications.
  - Indications for emergent surgical evaluation include acute volvulus, uncontrolled bleeding, obstruction, strangulation, perforation, or respiratory compromise.

PEARLS & CONSIDERATIONS

COMMENTS

- Gastric ulceration and erosions (*Cameron lesion*) can occur in the paraesophageal hernia pouch and are an uncommon cause of UGI bleeding.
- May cause iron deficiency anemia.
- Gastric volvulus or torsion can also occur and presents as dysphagia and postprandial pain.
- High incidence of esophagitis even after the eradication of *Helicobacter pylori*.
- The appearance of hiatal hernia may resemble a left atrial mass by echocardiography.

Hidradenitis Suppurativa

BASIC INFORMATION

DEFINITION

Hidradenitis suppurativa (HS) is a chronic, relapsing suppurative cutaneous disease affecting skin that bears apocrine glands and is manifested by abscesses, fistulating sinus tracts, and chronic infection leading to scarring.

SYNONYMS

Acne inversa
Apocrinitis
Verneuil disease
HS

ICD-10CM CODE
L73.2 Hidradenitis suppurativa

EPIDEMIOLOGY & DEMOGRAPHICS

Onset is postpubertal, with an average age of onset of 23 yr; rates decline after age 55 yr.
PREVALENCE: Overall prevalence in the United States is ~1% to 2%.
PREDOMINANT SEX: Female: male ratio is 3:1.
PREDOMINANT AGE: HS most often manifests after puberty, usually in the second or third decade of life. It is rare in the elderly.
RISK FACTORS:

- Obesity and metabolic syndrome
- Family history (approximately 30%)
- Hyperandrogenism in women
- Cigarette smoking

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The diagnosis is primarily clinical, based on the development of typical lesions in a characteristic distribution, with a relapsing nature. The course of HS is prolonged and marked by intermittent periods of activity and remission.

- Early symptoms include pain, itching, burning, erythema, and hyperhidrosis.
- Typical lesions include:
  1. Painful erythematous papules and nodules leading to painful abscesses with foul-smelling discharge.
  2. Dermal contractures and ropelike elevation of the skin.
  3. Comedones in the apocrine, gland-bearing skin.
- Classified into Hurley Stages (Table E1):
  1. Stage I: Abscesses without sinus tracts or scarring.
  2. Stage II: Multiple abscesses plus sinus tracts and scarring.
  3. Stage III: Diffuse involvement of entire area with abscesses, sinus tracts, and scarring.
- The axilla is the most common site (Fig. E1).
- Less common sites include the inguinal region, the breasts (more often in women), and the perineal or perianal skin (more often in men).
- There is a strong tendency toward relapse and recurrence.

TABLE E1 Hidradenitis Suppurativa—Grading Systems and Therapeutic Ladder

Hurley Staging System

- Stage I—one or more abscesses with no sinus tract or scar formation
- Stage II—one or more widely separated recurrent abscesses, with sinus tract and scar formation
- Stage III—multiple interconnected sinus tracts and abscesses throughout an affected region; more extensive scarring

Sartorius Grading System

- Anatomical regions involved: Axilla (left and/or right), groin (left and/or right), gluteal (left and/or right), or other region (e.g., inframammary): 3 points per region involved
- Number and scores of lesions for each region: Nodules = 1; fistulae = 6
- The longest distance between two relevant lesions* (i.e., nodules and fistulae) in each region: <5 cm = 1; 5-10 cm = 3; >10 cm = 9
- Are all lesions clearly separated by normal skin? In each region—yes 0/no (Hurley III) 9

Therapeutic Ladder

Indication	Therapeutic Interventions
General measures	• If obese or overweight, weight reduction • Reduce friction and moisture via loose undergarments, absorbent powders, and topical aluminum chloride • Antiseptic soaps • Smoking cessation
Hurley Stage I	• Intralesional triamcinolone (5 mg/ml) injections into early inflammatory lesions • Topical clindamycin • Eradication of *S. aureus* carriage with topical mupirocin in nose, axillae, umbilicus, and perianal regions • Oral antibiotics tailored to results of bacterial cultures from pustular discharge or abscess contents • Oral antibiotic therapy (alone or in combination) for its anti-inflammatory effect (rifampin + clindamycin, tetracycline, doxycycline, minocycline, dapsone, trimethoprim–sulfamethoxazole) • Oral anti-androgen therapy (e.g., finasteride)
Hurley Stage II	• Oral antibiotic therapy (see Stage I) • Acitretin • Systemic immunosuppressive agents including adalimumab,† infliximab, and cyclosporine • Surgical treatments‡ • Limited local excisions with second intention healing • CO_2 laser ablation with second intention healing • Nd:YAG laser treatments, at least 3-4 monthly sessions
Hurley Stage III	Medical treatments outlined for Stages I and II Surgical treatments‡ • Early wide surgical excision of involved areas • CO_2 laser ablation with second intention healing

†FDA-approved dosing regimen: 160 mg (four 40 mg injections) on day 1, *or* 80 mg daily on days 1 and 2 followed by 80 mg on day 15 and then 40 mg on day 29 and weekly thereafter.
‡Incision and drainage are discouraged given high rate of recurrence.
From Bolognia J: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.

- There is often a poor response to conventional antibiotics and no pathogens isolated from cultures of lesions.
- The disease is often mistaken for a simple infection and a long delay in diagnosis is common.
- Three clinical subtypes of HS have been recently proposed[1]:
  1. A classic axillary-mammary HS subtype, representing 48% of cases and characterized by breast and axillary involvement and hypertrophic scarring.
  2. A follicular HS subtype, representing 26% of cases manifesting primarily in male smokers with a family history of HS and characterized by follicular lesions, including epidermal cysts, pilonidal sinus, comedones, and severe acne.
  3. A gluteal HS subtype, representing 26% of cases, most often seen in smokers with lower body mass index (BMI) and with a morphology characterized by follicular papules, folliculitis, and gluteal involvement.

[1]Woodruff CM, Charlie AM, Leslie KS: Hidradenitis suppurative: a guide for the practicing physician, *Mayo Clin Proc* 90(12):1679-1693, 2015.

ETIOLOGY

- Keratinous materials plug apocrine glands in hair follicles leading to stasis, dilation, rupture, and re-epithelialization. Fig. E2 illustrates the pathogenesis of hidradenitis suppurativa.

FIG. E1 Hidradenitis suppurativa. A and **B,** Papulopustules, nodules, sinus tracts, and scarring in the axilla (Hurley stage II [A] and III [B]). **C,** Superficial sinus tracts that serve as a clue to the diagnosis, even in the absence of active disease. **D,** Severe disease with inflammatory nodules, hypertrophic scarring, draining fistulae, and sinus tract formation of the perianal region, buttocks, and upper thighs. This is the type of patient who is at risk for the development of squamous cell carcinoma and secondary amyloidosis. (**A,** Courtesy, Kalman Watsky, MD; **B,** Courtesy, Marco Romanelli, MD. In Bolognia J: *Dermatology,* ed 4, 2018, Elsevier.)

- Bacteria are trapped and multiply, leading to gland rupture with surrounding inflammation and local bacterial infection.
- Over time, repeated nodules and infections cause scarring, which can lead to deep tissue damage and sinus tracts.
- Infectious agents such as *Streptococcus, Staphylococcus,* and *Escherichia coli,* and enteric flora have been identified in cultures but are likely a secondary component of the disease.
- There is likely a significant genetic component to the disease. 35% to 40% of patients report a family history of HS. An HS spectrum of different phenotypes has been characterized involving genetic factors that are not yet well described but may be important for future therapy.
- HS has been associated with other endocrine and autoimmune disorders such as diabetes, Cushing syndrome, acromegaly, Crohn disease, and inflammatory arthritis.
- Metabolic syndrome affects as many as 50% of patients with HS and may exacerbate the associated inflammation.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Follicular pyodermias such as folliculitis, furuncles, carbuncles, and pilonidal cysts
- Noduloulcerative syphilis
- Cat scratch disease
- Granuloma inguinale
- Perianal and vulvar manifestations of Crohn disease
- Actinomycosis
- Lymphogranuloma venereum
- Dermoid, epidermoid, or Bartholin cysts
- Tuberculous inflammation of the skin
- Lymphadenitis
- Erysipelas

WORKUP

Primarily a clinical diagnosis based on typical lesions (see "Physical Findings & Clinical Presentation").

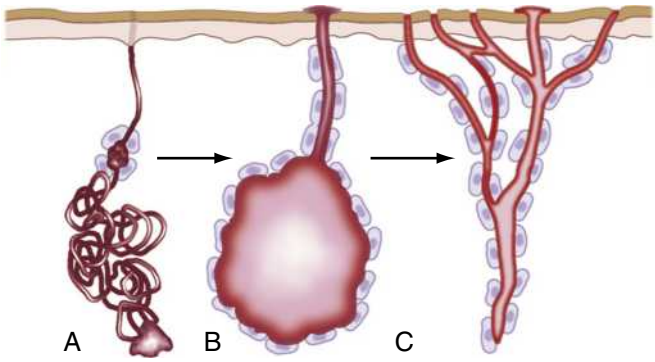

FIG. E2 Pathogenesis of hidradenitis suppurativa, an inflammatory disease of the apocrine sweat glands and adjacent connective tissue. A, The initiating event is occlusion of the apocrine duct by a keratinous plug. **B,** Bacteria are trapped beneath the keratinous plug and multiply to form an abscess, which can rupture into adjacent tissue. **C,** The end result is recurrent abscesses, chronic draining sinuses, and indurated scarred skin and subcutaneous tissues. Often, multiple tracts are interconnected and lead to the skin. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

LABORATORY TESTS

- Patients with acute lesions may have an elevated erythrocyte sedimentation rate or WBC.
- Febrile and toxic-appearing patients should have complete blood count, chemistries, and blood cultures.
- Any pus should be sampled for bacterial culture and sensitivity.

Rx TREATMENT

There is no definitive cure for hidradenitis.

NONPHARMACOLOGIC THERAPY

- Weight loss and control of metabolic syndrome
- Smoking cessation
- Avoidance of shaving, depilatory creams, deodorants
- Avoidance of tight-fitting clothing
- Warm compresses
- Incision and drainage of nonpurulent lesions is *not* recommended due to recurrence and scarring
- Laser therapy, radiotherapy, and cryotherapy currently under study
- Wide local excision for stage III disease with or without vacuum-assisted closure device

ACUTE AND CHRONIC Rx

- NSAIDs for inflammation and pain, consider gabapentin, pregabalin, SSRIs for chronic pain management.
- Antibiotics never proven to be effective; however, they are a mainstay of treatment. Can base treatment on the basis of aspirate culture and sensitivities or empirically.
  1. Clindamycin is the only topical antibiotic proven to be effective in randomized controlled trial and is appropriate for stage I disease.
  2. For oral therapy in stage II: Consider clindamycin and rifampin in combination. Cephalosporins, dicloxacillin, erythromycin, minocycline, and tetracycline have also been used.
  3. Severe, recurrent disease can require up to 3 to 6 mo of antibiotics.
- Oral contraceptives with low androgenic progesterone (norgestimate, desogestrel, or gestodene) for women show mixed effectiveness. They are especially advantageous for female patients of childbearing age who also require some form of birth control.
- Isotretinoin has been used with mixed effectiveness. It should be avoided in women of childbearing age.
- Metformin has mixed effectiveness, possibly due to related metabolic syndrome and hyperandrogenism.
- Trials using zinc gluconate 75 to 118 mg/day in patients with mild (grade 1) disease have shown mixed effectiveness.
- Corticosteroids and other immune suppressants such as cyclosporin, infliximab, and etanercept have been used for stage II disease, with mixed results.
- Adalimumab, an antitumor necrosis factor-α antibody given once per week (dose 40 mg/wk) has shown significantly higher clinical response as compared to placebo in phase 3 trials. Infliximab has also been used in trials with variable success rates, with most patients exhibiting clinical improvement within 8 wk.

COMPLICATIONS

- Squamous cell carcinoma
- Scarring leading to restricted limb mobility or lymphedema
- Rectal or urethral fistulas
- Psychological effects related to disfiguring nature of disease

REFERRAL

- Referral to dermatology during stage I to II disease.
- Referral to a surgeon is indicated for stage III disease.
- Surgical approaches include laser surgery and excisional surgery.

PEARLS & CONSIDERATIONS

COMMENTS

- Patients with hidradenitis are at risk for severe depression, social isolation, and negatively impacted sexuality as a result of their disease.
- There is an average delay in diagnosis of 12 yr and most patients are diagnosed in stage II of the disease.
- It is important to maximize nonmedical treatment, start medical treatment, and refer to a surgeon early in the disease course to ensure the best quality of life for patients.
- The only definitive treatment for hidradenitis is wide excision of the involved skin.

BASIC INFORMATION

DEFINITION

High-altitude illness refers to a spectrum of cerebral and pulmonary syndromes related to hypoxemia occurring during rapid ascent to high altitudes in unacclimatized individuals. Common acute syndromes include high-altitude pulmonary edema (HAPE), acute mountain sickness (AMS), and high-altitude cerebral edema (HACE). The latter two are thought to represent different points of severity along the same pathophysiologic process in the brain.

SYNONYMS

Altitude sickness
High-altitude headache
Acute mountain sickness
AMS
High-altitude pulmonary edema
High-altitude cerebral edema

ICD-10CM CODES

T70.29	Other and unspecified effects of high altitude
W94	Exposure to high and low air pressure and changes in air pressure

EPIDEMIOLOGY & DEMOGRAPHICS

- Millions of people worldwide are at risk of developing altitude sickness annually.
- 80% of people who ascend to high altitudes have high-altitude headache (HAH_2).
- AMS is the most common of the altitude diseases. It affects approximately 40% to 50% of people ascending to 14,000 ft (4200 m) from lowland and 25% of visitors to an altitude of 2000 m (6560 ft).
- The incidence of HACE is reported to be 0.1% to 2% at elevations in excess of 12,000 ft (3000 m). HACE is often complicated by concomitant HAPE.
- Men are five times more likely to develop HAPE than are women.
- AMS and HACE affect men and women equally.
- Some studies have suggested that climbers with a prior history of HAPE have a roughly 60% chance of recurrence if they ascend to the same elevation at the same rate.

PHYSICAL FINDINGS & CLINICIAL PRESENTATION (TABLE E1)

HAH_1
- Headache that develops within 24 hr of ascent.
- Bilateral, frontal or frontotemporal, dull or pressing quality.
- Mild to moderate intensity and aggravated by exertion, movement, straining, coughing, or bending.
- Headache resolves within 8 hr of descent.
- HAH should resolve with analgesics and/or 10 to 15 min of supplementary oxygen.
- Difficult to distinguish from headaches secondary to dehydration.

AMS
- AMS is thought to be a progression of HAH_2.
- Occurs within 6 to 12 hours after rapid ascent to 8000 ft (2500 m) in 10% to 25% of unacclimatized persons.
- Headache is the most common symptom.
- Dizziness and light-headedness.
- Nausea, vomiting, and loss of appetite.
- Fatigue.
- Sleep disturbance from an exaggerated hyperventilatory phase of Cheyne-Stokes respiration in response to hypoxemia and alkalosis.
- AMS can evolve into HAPE and HACE.
- Retinal hemorrhages can be present from increased blood flow or breakdown in the blood-retinal barrier.
- Supplemental oxygen may be used to support the clinical diagnosis.

HACE
- Usually presents several days after AMS.
- Headache, nausea, vomiting, mild fever, confusion, irritability, drowsiness, stupor, hallucinations, seizures, and paralysis.
- Truncal ataxia and encephalopathy.
- Coma and death from brain herniation may develop within hours of the first symptoms.

HAPE (Fig. E1)
- Typically occurs 2 to 4 days after ascent to more than 8000 ft (2500 m)
- It can occur at a lower elevation in patients with pulmonary hypertension
- Dyspnea out of proportion to the level of exertion, loss of stamina
- Dry cough or cough with frothy rust- or pink-tinged sputum
- Chest tightness
- Tachycardia, tachypnea, rales, cyanosis

ETIOLOGY

- During ascent to altitudes above sea level, the atmospheric pressure decreases. Although the percentage of oxygen in the air remains the same, the partial pressure of oxygen decreases with increased altitude, and can cause hypoxemia. Fig. E2 illustrates the effect of altitude on alveolar Pao_2 and oxygen saturation.
- Increased cerebral blood flow and the loss of autoregulation of intracranial pressure may contribute to increased cerebral vascular permeability and subsequent brain edema (HACE).
- Hypobaric hypoxia can trigger elevated pulmonary pressures, resulting in protein-rich, hemorrhagic exudates into the lung alveoli due to a breakdown in the pulmonary blood-gas barrier (HAPE).
- The body responds to low oxygen partial pressures through a process of acclimatization (see "Comments").

DIAGNOSIS

Made by clinical presentation and physical findings

DIFFERENTIAL DIAGNOSIS

- Dehydration
- Carbon monoxide poisoning
- Hypothermia
- Infection
- Substance abuse
- Congestive heart failure
- Pulmonary embolism
- Cerebrovascular accident
- Box E1 summarizes the differential diagnosis of high-altitude illnesses

WORKUP

Typically the diagnosis is self-evident after history and physical examination. Laboratory tests and imaging studies help monitor cardiopulmonary and central nervous system status in patients admitted to the intensive care unit for pulmonary and/or cerebral edema. In patients with HAPE occurring at lower altitudes (<8000 ft), an evaluation of preexisting pulmonary hypertension or a left-to-right shunt should be considered.

LABORATORY TESTS

Not useful, unless to rule out an alternative diagnosis

IMAGING STUDIES

- Chest x-ray showing Kerley B-lines and patchy edema (see Fig. E1)
- CT scan of the head showing diffuse or patchy edema
- MRI of the head showing characteristic intense T2 signal in the white matter

TREATMENT

NONPHARMACOLOGIC THERAPY

- Stop the ascent to allow acclimatization or start to descend until symptoms have resolved.
- Patient with AMS can stay at the same height and may ascend once symptoms resolve but should strongly consider using acetazolamide for the remainder of the trip.
- If the symptoms recur or fail to resolve after 2 to 3 days, descent is indicated.
- Descent is the definitive treatment and should begin immediately at the first suspicion of HACE.
- Oxygen 4 to 6 L/min is used for severe AMS, HAPE, and HACE.
- Portable hyperbaric bags are useful if available at the site.
- Altitude can cause diuresis that may be mediated by enhanced release of atrial natriuretic peptide. When coupled with the increased fluid loss through increased ventilation, there is a higher risk for dehydration, and adequate hydration should be maintained.

ACUTE PHARMACOLOGIC Rx

- Nonsteroidal antiinflammatory drugs (e.g., ibuprofen 600 mg every 6 hours, beginning 6 hours before ascending) are often used for prophylaxis of traditional altitude sickness and in treating headaches in AMS. However trials have shown that ibuprofen is slightly inferior to acetazolamide for acute mountain sickness prevention, and should not be recommended over acetazolamide for rapid ascent.[1]

[1] Burns P et al: Altitude sickness prevention with ibuprofen relative to acetazolamide, *Am J Med* 132(2):247-251, 2019.

- Acetazolamide 125 to 250 mg PO bid is the preferred agent and has been effective for both prevention and acute therapy in patients with AMS and HACE. Dexamethasone is equally effective to reduce symptoms of AMS and can be used as an alternative to acetazolamide. It should also be added to acetazolamide in patients with HACE.
- Nifedipine 10 mg sublingual followed by long-acting nifedipine 30 mg bid is used for patients with HAPE who cannot descend immediately. Salvage therapy in absence of supplemental oxygen and descent also includes phosphodiesterase-5 inhibitors (sildenafil or tadalafil).
- Dexamethasone 4 mg PO every 6 hr is used in patients with severe AMS, HAPE, or HACE.

CHRONIC Rx

Prevention is the most prudent therapy.

- Slow, staged ascent to avoid altitude sickness.
- Start the ascent below 8000 ft.
- Ascend 1000 ft/day (300 m/day).
- Spend two nights at the same altitude every 3 days.
- Sleep at lower heights than the altitude climbed ("climb high, sleep low").
- Prophylactic therapy with NSAIDs (ibuprofen 600 mg every 6 hours, beginning 6 hours before ascending) or acetazolamide up to 750 mg daily and/or dexamethasone 8 to 16 mg daily decreases the risk of developing AMS (combination may have additive benefit). The drugs should be used until acclimatization occurs.
- Prophylactic inhalation of a β-adrenergic agonist, salmeterol 125 mcg q12h, or the use of slow-release nifedipine 20 mg bid have both been shown to reduce the risk of HAPE in susceptible individuals.
- Tadalafil, a long-acting phosphodiesterase inhibitor, has recently been shown to decrease the incidence of HAPE in susceptible individuals.
- Box 2 summarizes field treatment of high-altitude illness.

DISPOSITION

- AMS improves over a period of 2 to 3 days.
- HAPE is the most common cause of death among patients with altitude illnesses.
- More than 60% of patients with HAPE will have recurrence of symptoms on subsequent climbs.
- In HACE, neurologic deficits may persist for wks but eventually resolve. If coma occurs, prognosis is poor.

REFERRAL

Cardiology and neurology referrals are made in patients with pulmonary edema and central nervous system findings, respectively.

PEARLS & CONSIDERATIONS

COMMENTS

- Acclimatization is the process in which an individual who normally resides at low altitudes adapts to hypobaric hypoxia to improve tolerance and performance at higher altitudes. These mechanisms include:
  1. An increase in respiratory rate and tidal volume. This hyperventilation allows lowering of arterial carbon dioxide to preserve oxygen delivery, even at extreme altitudes.
  2. An early increase in heart rate and stroke volume to improve oxygen delivery. After 1 wk, both parameters decrease because of diuresis and lower catecholamine levels.
  3. Pulmonary hypertension develops in response to hypoxemia, resulting in improvement of the ventilation-perfusion mismatch but may be maladaptive and lead to the development of HAPE.
  4. Cerebral vasodilation to increase blood flow to the brain.
  5. Rise in hemoglobin and hematocrit. This is a long-term process that takes up to 1 wk to occur in response to the need for improved oxygen delivery.
- Adaptation to altitude is different from acclimatization and refers to physiologic differences in permanent residents at high altitude (e.g., an increased oxygen diffusion capacity).
- High-altitude illness can generally be prevented by ascending to 300 to 500 m/day at altitudes above 3000 m and including a rest day every 3 to 4 days.
- Risk factors for the development of altitude sicknesses are:
  1. Rapid ascent
  2. Previous history of altitude sickness
  3. Strenuous exertion on arrival
  4. Obesity
  5. Male gender
- Physical fitness is not protective against high-altitude illness.
- Both dexamethasone and tadalafil decrease systolic pulmonary artery pressure and may reduce the incidence of HAPE in adults with a history of HAPE. Dexamethasone prophylaxis may also reduce the incidence of AMS in these adults.
- Descent is mandatory for all persons with HACE or HAPE.
- The American College of Chest Physicians has released a primer on caring for passengers with a variety of health conditions who are traveling to high-altitude places or areas (http://www.accpstorage.org/newOrganization/patients/TravelingwithOxygen.pdf). Specific indications for supplemental oxygen are provided in the document.

BOX 2 Field Treatment of High-Altitude Illness

High-Altitude Headache and Mild Acute Mountain Sickness
- Stop ascent, rest, acclimatize at same altitude
- Symptomatic treatment as necessary with analgesics and antiemetics
- Consider acetazolamide, 125 to 250 mg bid, to speed acclimatization
- OR descend 500 m (1640 ft) or more

Moderate to Severe Acute Mountain Sickness
- Low-flow oxygen, if available
- Acetazolamide, 125 to 250 mg bid, with or without dexamethasone, 4 mg PO, IM, or IV q6h
- Hyperbaric therapy
- OR immediate descent

High-Altitude Cerebral Edema
- Immediate descent or evacuation
- Oxygen, 2 to 4 L/min
- Dexamethasone, 8 mg PO, IM, or IV, then 4 mg q6h
- Hyperbaric therapy

High-Altitude Pulmonary Edema
- Minimize exertion and keep warm
- Immediate descent or hyperbaric therapy
- Oxygen, 4 to 6 L/min until improving, then 2 to 4 L/min

If above unavailable, one of the following:
- Nifedipine, 30 mg extended release q12h
- Sildenafil 50 mg q8h
- Tadalafil 10 mg q12h
- β-agonists may be helpful

Periodic Breathing
- Acetazolamide, 62.5 to 125 mg at bedtime as needed

bid, Twice a day; *IM,* intramuscularly; *IV,* intravenously; *PO,* orally.

FIG. E1 Chest radiograph showing high-altitude pulmonary edema. (From Strauss RH [ed]: *Sports medicine,* ed 2, Philadelphia, 1991, WB Saunders.)

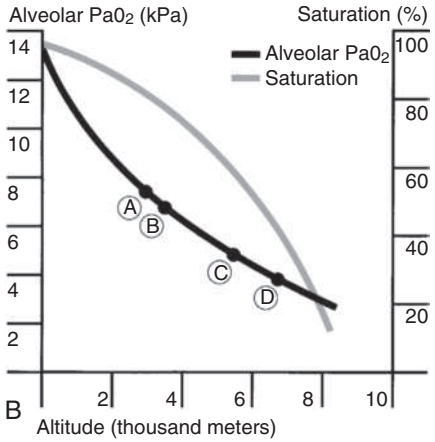

FIG. E2 Effect of altitude on alveolar PaO_2 and oxygen saturation. Because of the steep slope of the oxygen dissociation curve, increasing altitude to greater than 5000 m causes abdominal cramps and nausea. **A,** 3500 m (12,000 ft)—headache, nausea, diminished visual acuity, and possible precipitous fall in saturation. In an unacclimated person, acute change occurs at **(B)** 3000 m (10,000 ft)—slightly impaired memory and judgment, increased heart rate, and pulmonary edema. **C,** 5500 m (18,000 ft)—impaired consciousness after several hours in many people. **D,** 6750 m (22,000 ft)—loss of consciousness. (From Souhami RL, Moxham J: *Textbook of medicine,* ed 4, London, 2002, Churchill Livingstone.)

BOX E1 Differential Diagnosis of High-Altitude Illnesses

Acute mountain sickness and high-altitude cerebral edema	Dehydration, exhaustion, viral or bacterial infection, alcohol hangover, hypothermia, carbon monoxide poisoning, migraine, hyponatremia, hypoglycemia, diabetic ketoacidosis, CNS infection, transient ischemic attack, arteriovenous malformation, stroke, seizures, brain tumors, ingestion of toxins or drugs, acute psychosis
High-altitude pulmonary edema	Asthma, bronchitis, pneumonia, mucus plugging (secondary to previous), idiopathic hyperventilation syndrome, pulmonary embolism, heart failure, myocardial infarction

CNS, Central nervous system.
From Auerbach P: *Wilderness medicine, expert consult,* premium edition—enhanced online features and print, Philadelphia, 2012, WB Saunders.

BASIC INFORMATION

DEFINITION

Hip fractures refer to fractures of the proximal part of the femur and can be classified as intracapsular or extracapsular. Intracapsular fractures include fractures of the femoral head and femoral neck (Fig. E1, Table E1). Extracapsular fractures include intertrochanteric fractures, subtrochanteric fractures and, less commonly, greater or lesser trochanteric fractures. These fractures can be further categorized by the fracture pattern and stability.

SYNONYMS

Hip fracture
Proximal femur fracture
Intracapsular fracture: Femoral neck fractures (subcapital vs. transcervical vs. basicervical)
Extracapsular fracture: Intertrochanteric, peritrochanteric, or subtrochanteric fractures

ICD-10CM CODES
Code x Y (Y = encounter type: A [initial], D [subsequent with routine healing], G [subsequent with delayed healing], K [subsequent with nonunion], P [subsequent with malunion], S [sequelae]).

S72.0	Fracture of neck of femur
S72.1	Pertrochanteric fracture
S72.2	Subtrochanteric fracture
S72.3	Fracture of shaft of femur
S72.4	Fracture of lower end of femur
S72.7	Multiple fractures of femur
S72.8	Fractures of other parts of femur
S72.009	Fracture of unspecified part of neck of unspecified femur
M84.359xY	Stress fracture hip, unspecified
M84.459xY	Pathologic fracture of the hip, unspecified
M85.353xY	Stress fracture unspecified femur

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Lifetime risk in women ~16%
INCIDENCE: 350,000 hip fractures annually in the U.S.
EPIDEMIOLOGY:
- Female > male
- Caucasian > African American
- 90% >65 yr old
- Mean age, 80 yr old

MORTALITY: 20% to 25% mortality within the first yr following the fracture

RISK FACTORS

- Osteoporosis
- Age >75 yr old
- Gait instability, foot deformities, and muscular weakness
- Sensory impairment such as neuropathy
- Polypharmacy
- Impaired cognition, depression
- Use of alcohol or benzodiazepines
- Orthostatic hypotension
- Environmental hazards at home (e.g., loose rugs, exposed cords)
- Subclinical hyperthyroidism

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Hip or groin pain
- Displaced fractures: Affected extremity may be shortened and externally rotated (less often internally rotated)
- Impacted/stressed/nondisplaced fracture: Pain with motion or ambulation; often without obvious deformity
- Ecchymosis or bruising about the hip
- Inability to bear weight and tenderness to palpation

ETIOLOGY

- Trauma
- Age-related bone fragility secondary to osteoporosis or decreased bone mineral density
- Increased risk of fractures in elderly (decline in muscle function, reduced bone quality, polypharmacy, or use of psychotropic medication, etc.)
- Stress fractures

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Osteoarthritis/rheumatoid arthritis of the hip
- Hip dislocation
- Pathologic fracture
- Muscle strain or tendonitis
- Lumbar disk syndrome with radicular pain
- Insufficiency fracture of pelvis or pubic ramus fracture
- Trochanteric bursitis
- Septic hip joint
- Pelvic fracture
- Lateral femoral cutaneous nerve entrapment (meralgia paresthetica)
- Labral tear or pathology
- Paget disease
- Neoplasm

WORKUP

In most cases, the diagnosis is based on clinical presentation and plain radiographs (Figs. E2 and E3). Fig. E4 illustrates the Garden classification of femoral neck fractures, which classifies the fracture based on the amount of displacement or gapping between the fracture fragments and relative stability of the fracture pattern. Additional imaging may be required to aid in the diagnosis of subtle hip fractures not evident on plain radiographs (e.g., MRI for stress or occult fractures).

IMAGING STUDIES

- Standard radiographs should include an anteroposterior view of the pelvis and hip, and a cross-table lateral view of the hip to confirm the diagnosis. Full-length femur and knee films should also be obtained.
- If initial radiographs are negative, then computed tomography (CT) or MRI may be indicated. Stress fractures can be diagnosed

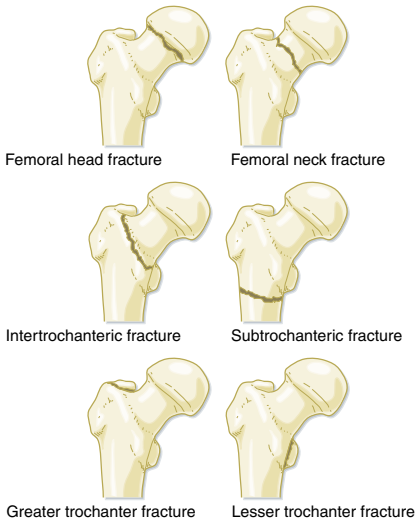

FIG. E1 Types of hip fractures. (From Adams JG et al: *Emergency medicine, clinical essentials,* ed 2, Philadelphia, 2013, Elsevier.)

TABLE E1 Garden Classification of Femoral Neck Fractures

Type I	Nondisplaced, slightly impacted, incomplete fracture line The medial trabeculae of the femoral head and neck form an angle of 180 degrees The femoral head is tilted into valgus The distal fragment lies in external rotation
Type II	Nondisplaced, complete fracture line The medial trabeculae of the femoral head and neck form an angle of 160 degrees Nondisplaced femoral head Normal distal alignment
Type III	Complete fracture line, with displacement <50% The femoral head trabeculae are not in alignment with those of the pelvis The femoral head is tilted into varus and medially rotated The distal fragment lies in external rotation
Type IV	Complete fracture line, with displacement >50% and dissociation The femoral head trabeculae lie in alignment with those of the pelvis The femoral head is detached and frequently realigns with the acetabulum The distal fragment is proximally displaced and lies in external rotation

From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2014, Saunders.

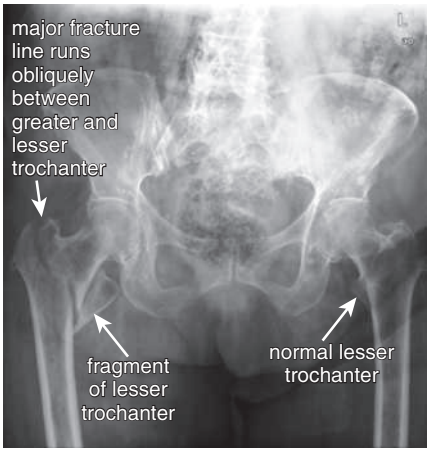

FIG. E2 Intertrochanteric femur fracture: Three parts (proximal, distal, and one trochanter). Intertrochanteric femur fractures are common, with the mechanism often being a fall from standing in an elderly patient. The major fracture line usually runs obliquely between the greater and the lesser trochanters. These fractures may have two, three, or four parts classically, although severely comminuted combinations are also possible. Two-part fractures consist of the proximal and distal fragments. Three-part fractures also include a fragment of one trochanter. Four-part fractures include fragments of both trochanters. This 86-yr-old woman had an unwitnessed fall. She has a typical three-part fracture, with a fragment of the lesser trochanter visible. Note her generalized severe osteopenia. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

with CT scan; however, MRI is the preferred study for the diagnosis of occult fractures. Bone scanning may also be used to identify fractures.

Rx TREATMENT

- Orthopedic consultation: The majority of hip fractures are treated surgically, with nonoperative management reserved for patients with significant medical comorbidities, severe dementia, or patients who are nonambulatory preinjury.
- Preoperative workup: CBC, BMP, type and screen, coagulation panel, chest radiograph, ECG, and urinalysis.
- Surgery is indicated in most cases, with the goal of surgical fixation within 24 to 48 h. Repair within 24 h is associated with lower complication rates and lower 30-day mortality. Treatment depends on fracture pattern and stability:
  1. Femoral neck, nondisplaced/valgus impacted: Internal fixation with 3 cannulated screws
  2. Displaced femoral neck: <65 yr old: Urgent anatomic reduction, cannulated screws or dynamic hip screw (DHS)
  3. Displaced femoral neck >65 yr old: Total hip arthroplasty for healthy, active patients and hemiarthroplasty for frail or sick patients
  4. Intertrochanteric fractures: Intramedullary nail (IMN) or dynamic hip screw (DHS)
  5. Unstable intertrochanteric/reverse obliquity: IMN, blade plate, dynamic condylar screw (not DHS)
- Deep vein thrombosis (DVT) prophylaxis (enoxaparin, fondaparinux, heparin). Mechanical DVT prophylaxis in the nonaffected limb. Pharmacologic DVT prophylaxis is usually continued for 14 to 30 days postoperatively.
- Pain management: Effective pain management is a primary goal in hip fracture. Opioid analgesics have a high incidence of delirium and constipation. Nerve blockade is effective in reducing acute pain following a hip fracture. A bowel regimen and adequate hydration are recommended in patients taking narcotics.
- Prophylactic antibiotics should be administered before surgery and continued for 24 hours after surgical repair.
- Rehabilitation is a major component of hip fracture treatment and should be initiated on the first day postoperatively.
- Conservative therapy and pain control should be considered in patients who are not surgical candidates (e.g., significant medical risk, bed-/wheelchair-bound, or severe dementia).

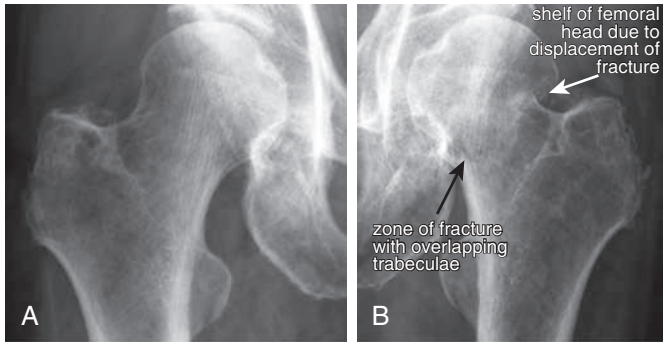

FIG. E3 Femoral neck fracture. This 84-yr-old woman had an unwitnessed fall. **A,** Normal right hip, osteoporotic. **B,** Left hip, another relatively subtle femoral neck fracture. Note the smudging of the trabeculae of the femoral neck. In addition, the distal fragment has shifted medially, creating an overhanging ledge of the femoral head not seen on the opposite normal side. Some femoral neck fractures are more obvious. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

DISPOSITION

- Mortality associated with surgery typically ranges from 2% to 4% but varies based on the patient's risk profile. Elderly patients have a fivefold to eightfold increased risk for all-cause mortality during the first 3 mo after a hip fracture.
- Mortality rate within 1 yr in elderly patients is 20% to 30%.
- Increased annual mortality persists over time for both women and men, but at any given age, the annual mortality following a hip fracture is higher in men than in women.
- Dementia is a particularly poor prognostic sign.

REFERRAL

To orthopedic surgeon for surgical consideration when the diagnosis is made

PEARLS & CONSIDERATIONS

COMMENTS

- Complications: Nonunion, malunion, infection, avascular necrosis, DVT, delirium, decubitus ulcers, persistent pain, loosening of prosthesis, and periprosthetic fractures.
- Nonoperative management:
  1. Should be considered for nonambulatory patients, patients with severe dementia, or patients who are at high risk of complications associated with surgery (e.g., severe cardiac or pulmonary disease).
  2. Early bed-to-chair mobilization and vigilant nursing care to avoid skin breakdown and decubitus ulcers.
  3. Patients may experience pain relief prior to physiologic union of the fracture.
- Severe groin pain or inability to ambulate may be the only finding associated with an occult fracture of the femoral neck. If suspected, MRI can be obtained.
- In the U.S., hip fracture rates and subsequent mortality among persons aged ≥65 yr old are declining, and comorbidities among patients with hip fractures are very expensive ($40,000 in the first yr following hip fracture for direct medical costs and $5000 in subsequent yrs). The estimated cost related to hip fractures was >$20 billion in 2007.
- Fragility (or low-energy) hip fractures are common in elderly patients with reduced bone quality. These types of fractures are associated with a 1-yr mortality of 26% and 58% of patients requiring long-term care in a nursing facility. Diagnosis of a fragility fracture of the hip is associated with a second fragility fracture within the next 5 yr.
- Concurrent prolonged use of proton-pump inhibitors (≥1 yr) is associated with reduced effectiveness of alendronate for preventing hip fractures in older adults.

PREVENTION

- The rate of hip fracture could be reduced by:
  1. Elimination of environmental hazards (e.g., poor lighting, loose rugs, low sitting furniture)
  2. Regular exercise for balance and strength
  3. Patient education about fall prevention
  4. Medication review to minimize side effects and polypharmacy
  5. Prevention and treatment of osteoporosis (e.g., calcium/vitamin D, resistance exercise, reversal of underlying pathology)

BASIC INFORMATION

DEFINITION

Hirsutism is the development of stiff, pigmented (terminal) facial and body hair (male distribution) in women as a result of excess androgen production.

SYNONYM

Excessive hair growth

ICD-10CM CODE
L68.0 Hirsutism

EPIDEMIOLOGY & DEMOGRAPHICS

- Overall prevalence unknown, estimated 5% to 10% in reproductive age women.
- Race and genetics should be considered. Some distinct ethnic populations have minimal body hair and others (Mediterranean, Middle Eastern, South Asian) have moderate to large amounts of body hair while serum androgen levels are similar.
- Social norms and culture also determine how much body hair is cosmetically acceptable.
- Half of all cases of mild hirsutism do not have hyperandrogenemia. "Patient-important hirsutism" refers to hirsutism causing woman sufficient distress to seek care.
- Incidence and presentation of hirsutism is dependent on underlying cause of androgen excess (see "Differential Diagnosis").
- Most women with hirsutism have polycystic ovary syndrome (PCOS). PCOS accounts for 95% of cases of hirsutism.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Timing of symptoms: Abrupt onset, short duration, rapid progression, progressive worsening, more severe signs of virilization (Fig. E1), or later age of onset suggest androgen-producing tumor, late-onset congenital adrenal hyperplasia, or Cushing syndrome. Weight increases may produce increased androgen production.
- Menstrual history: Menarche, cycle regularity and symptoms of ovulation, fertility, and contraception use. Anovulatory cycles are the most common underlying cause of androgen excess.
- Medication use history: Some drugs cause hirsutism or produce androgenic effects (danazol, phenytoin, valproic acid, androgenic progestins [e.g., norgestrel], cyclosporin, minoxidil, metoclopramide, phenothiazines, methyldopa, diazoxide, and penicillamine).
- Family history: Known or suspected family history of hirsutism, congenital adrenal hyperplasia, insulin resistance, polycystic ovary syndrome (PCOS), infertility, obesity, menstrual irregularity may be found.
- Physical exam reveals deepening voice, body habitus, increased muscle mass, galactorrhea; abdominal and pelvic exam.
- Associated cutaneous manifestations (Fig. E2) are acne, acanthosis nigricans, striae, hair distribution, location and quantity, frontotemporal balding, muscle mass, clitoromegaly.
- Ferriman-Gallwey scale, a simple, pictorial system of scoring nine body areas, is the most common tool used to quantify hirsutism. It may be unreliable in non-Caucasian women of other ethnicities.

ETIOLOGY

- Presence of hirsutism indicates androgen excess. Total testosterone may be normal, but free testosterone is elevated.
- Androgens induce vellus hair follicles (soft, unpigmented hair) in sex-specific areas (upper lip, chin, midsternum, upper abdomen, back, buttocks) to develop into thicker, more heavily pigmented terminal hairs.
- Anovulatory ovaries are usual source of excess androgens through thecal cell steroidogenesis and conversion of androstenedione to testosterone. The most common cause of hirsutism is polycystic ovary syndrome, which accounts for three out of every four cases.
- Conditions that decrease hepatic production of sex hormone binding globulin (SHBG) decrease protein-bound testosterone and increase free testosterone fraction (e.g., low estrogen, high androgen, and hyperinsulinemic states).
- Late-onset, congenital adrenal hyperplasia enzyme deficiency (most commonly 21-hydroxylase deficiency) produces excess 17 hydroxyprogesterone (17-OHP) and overproduction of androstenedione.
- Rare ovarian tumors primarily derived from Sertoli-Leydig cells, granulosa theca cells, or hilus cells produce excess androgens.
- Rare adrenal tumors produce excess androgens.
- Rare pituitary or hypothalamic tumors produce excess prolactin and can lead to anovulation.
- Box E1 summarizes causes of androgen excess in women of reproductive age.

FIG. E1 Hirsutism. (From James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, WB Saunders.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Androgen-independent vellus hair: Soft, unpigmented hair that covers entire body
- Hypertrichosis: Diffusely increased total body hair (vellus or lanugo-type) not restricted to androgen-dependent areas often an adverse response to a medication or systemic illness (e.g., anorexia nervosa, porphyria, malnutrition, hypothyroidism)
- PCOS 75%
- Idiopathic 5% to 15%
- Congenital adrenal hyperplasia 1% to 8%
- Insulin resistance syndrome 3% to 4%
- Cushing syndrome <1%
- Drug induced <1%
- Ovarian tumor <1%
- Adrenal tumor <1%
- Hyperthecosis <1%
- Hyperprolactinemia <1%

WORKUP

- Hirsutism is a clinical diagnosis.
- Management of hirsutism is largely independent of the etiology.
- Workup in selected hirsute women is directed to determine underlying cause of androgen excess.
- See specific conditions for more detailed workup of individual diagnoses.

LABORATORY TESTS

Establishing laboratory evidence of excess androgens in women with moderate or severe hirsutism, sudden onset, rapid progression, or associated menstrual dysfunction, central obesity, clitoromegaly, or acanthosis nigricans is an approach consistent with guidelines from the Endocrine Society, the American College of Obstetricians and Gynecologists, the Androgen Excess and Polycystic Ovary Syndrome Society, and the American Association of Clinical Endocrinologists.

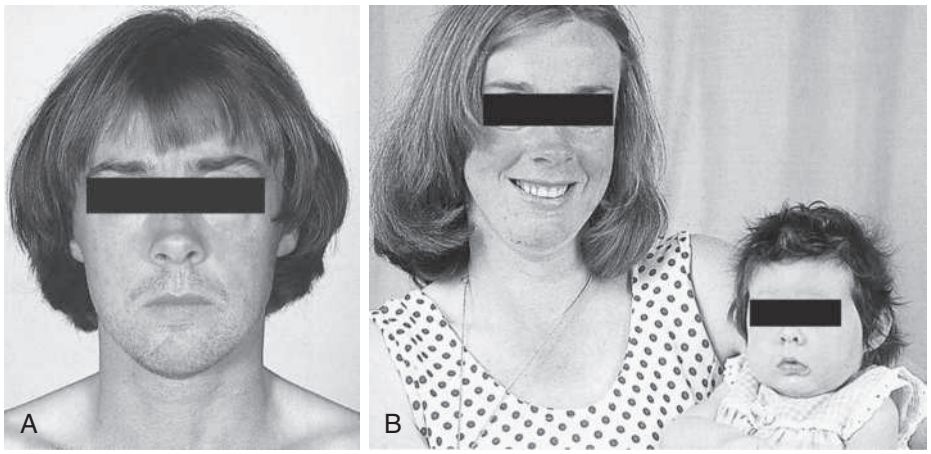

FIG. E2 A patient with an arrhenoblastoma with associated polycystic ovaries before and after treatment. A, Before treatment, the patient had marked facial hirsutism. **B,** The patient is shown successfully treated. The tumor was resected and ovulation ensued with clomiphene and human chorionic gonadotropin therapy. (From Besser CM, Thorner MO: *Comprehensive clinical endocrinology,* ed 3, St Louis, 2002, Mosby.)

BOX E1 Causes of Androgen Excess in Women of Reproductive Age

Ovarian
Polycystic ovary syndrome (PCOS)
Hyperthecosis (a severe PCOS variant)
Ovarian tumor (e.g., Sertoli-Leydig cell tumor)

Adrenal
Nonclassic adrenal hyperplasia
Cushing syndrome
Glucocorticoid resistance
Adrenal tumor (e.g., adenoma, carcinoma)

Specific Conditions of Pregnancy
Luteoma of pregnancy
Hyperreaction luteinalis
Aromatase deficiency in fetus

Other
Hyperprolactinemia, hypothyroidism
Medications (danazol, testosterone, anabolizing agents)
Idiopathic hirsutism (normal serum testosterone in an ovulatory woman)
Idiopathic hyperandrogenism (patients who do not fall into any of the other categories listed)

From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, WB Saunders.

- Total plasma testosterone (normal range 20-60 ng/dl [0.69-2.1 nmol/L]) or free testosterone: Early morning on day 4 to 10 of menstrual cycle to screen for testosterone-secreting tumors. If moderately or markedly elevated (total testosterone >150 ng/dl [5.2 nmol/L], free testosterone >2 ng/dl [0.07 nmol/L]) may image adrenals and ovaries for androgen-secreting tumors

Other laboratory test considerations if appropriate:

- Prolactin: Moderately elevated values should prompt imaging of pituitary-hypothalamic region.
- 17-OHP (17 α-hydroxyprogesterone): Screen for adrenal enzyme deficiencies. Morning value >200 ng/dl in early follicular phase suggests nonclassic (late onset) congenital adrenal hyperplasia due to 21-hydroxylase deficiency and may be confirmed with high-dose (250 mcg) ACTH stimulation test.
- Thyroid-stimulating hormone (TSH): Rule out hypothyroidism.
- Dehydroepiandrosterone sulfate (DHEA-S): Screen for adrenal androgen production as almost entirely produced by adrenals. Levels >700 mcg/dl (13.6 nmol/L) raise suspicion for adrenal androgen-secreting tumor.

Additional laboratory test considerations if appropriate:

- Follicle-stimulating hormone (FSH): Rule out hypoestrogenic state (perimenopausal)
- Luteinizing hormone (LH): Typically elevated in PCOS with low or normal FSH
- 24-hour urinary free cortisol: Rule out Cushing syndrome and overproduction of cortisol
- Overnight single-dose dexamethasone suppression test: Rule out Cushing syndrome and adrenal hyperfunction
- Fasting blood sugar (FBS), 2-hr 75-g oral glucose tolerance test, fasting insulin levels: Rule out insulin resistance syndrome
- Table E1 summarizes laboratory tests for the differential diagnosis of androgen excess

IMAGING STUDIES

Imaging study considerations if appropriate:

- Pelvic ultrasound (high resolution, transvaginal): Rule out ovarian tumor if total testosterone is elevated.
- Abdominal CT/MRI: Rule out adrenal tumor if elevated DHEAS.
- Pituitary-hypothalamic region CT/MRI: Rule out pituitary tumor if prolactin elevated.
- Laparoscopy/laparotomy: Rule out small ovarian tumor in cases of elevated testosterone levels without radiologic evidence of adrenal or ovarian pathology.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Weight reduction: Can reduce androgen production indirectly by reducing insulin-stimulated theca cell androgen production and improve menstrual function, and slow hair growth in obese women
- Cosmetic: Temporary:
  1. Shaving: Does not stimulate hair growth; lasts days, leaves stubble
  2. Epilation: Electronic plucking
  3. Bleaching: Removes hair pigment. May cause skin irritation
  4. Mechanical waxing/plucking
  5. Depilatories: Gels, lotions, or creams that chemically disrupt sulfide bonds of hair causing dissolution of hair shaft. No stubble
  6. Photoepilation (laser and intense pulsed light [IPL]): Hair follicles destroyed by wavelengths of light absorbed by melanin. Good for pigmented hair; laser treatment is more effective than shaving, waxing, and electrolysis. It lasts 3 to 6 mo as vellus follicles remain and can be converted to terminal pigmented hair under excess androgens
- Cosmetic: Permanent. Electrolysis: Destroys individual hair follicles. May be expensive and time consuming

ACUTE GENERAL Rx

See "Pharmacologic Therapy."

CHRONIC Rx

See "Pharmacologic Therapy."

PHARMACOLOGIC THERAPY

- Usually second-line treatment following nonpharmacologic, physical methods of hair control, and in consideration of patient's comorbidities and risk factors, patient preferences, area of excess hair amenable to treatment, and access and affordability of treatments
- Pharmacologic treatments categorized as topical, oral contraceptive pills (OCPs), antiandrogens (potential adverse effects on a developing male fetus, so use with reliable contraception), other treatments directed at specific underlying etiology

TABLE E1 Laboratory Tests for the Differential Diagnosis of Androgen Excess

Initial Testing

Total testosterone
Prolactin
Thyroid-stimulating hormone

Further Testing Based on Clinical Presentation

17-Hydroxyprogesterone (8:00 A.M.)
17-Hydroxyprogesterone 60 min after IV ACTH
Cortisol (8:00 a.m.) after 1 mg dexamethasone at midnight
DHEAS
Androstenedione
Imaging of ovaries (transvaginal ultrasonography)
Imaging of adrenals (abdominal ultrasonography, CT, MRI)
Nuclear imaging after IV administration of radiolabeled cholesterol

ACTH, Adrenocorticotropic hormone; *CT,* computed tomography; *DHEAS,* dehydroepiandrosterone sulfate; *IV,* intravenous; *MRI,* magnetic resonance imaging.
From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, WB Saunders.

- Topical: Eflornithine topical cream 13.9%: Unclear mechanism of action; may inhibit ornithine decarboxylase, retarding hair growth. Temporary cosmetic treatment for facial hair. Applied directly to unwanted facial hair bid with at least 8-hr spaced applications. Does not remove hair, rather slows growth. Slow response over 4 to 8 wk. Hair growth returns upon discontinuation of treatment
- OCPs: Suppress ovarian steroidogenesis and LH through low-dose estrogen and low androgenic progestational agents. Slow response to treatment. Suppresses new hair growth. Established hair unaffected. Low-dose OCPs with low androgenic progestational agents, for example, desogestrel, drospirenone, norgestimate. Avoid norgestrel and levonorgestrel (higher androgenic progestational agents)
- Antiandrogens: Spironolactone: When OCPs unacceptable or may be added for disappointing results after 6 mo of OCP treatment:
  1. Aldosterone-antagonist diuretic inhibits adrenal and ovarian biosynthesis of androgens. May result in ovulation, so consider contraception needs
  2. Slow response usually 6 mo or more
  3. 200 mg PO qd, then decrease to 25 to 50 mg qd maintenance
  4. May cause hyperkalemia
  5. Anovulatory, unopposed estrogen states require progestin management

REFERRAL

- To endocrinologist if difficulty in determining diagnosis, achieving therapeutic goals, or resistant to first-line therapies. Prepubertal and postmenopausal hirsutism is suspicious for neoplastic or secondary endocrine causes and should be referred for further evaluation
- Consider referral or consultation for following therapies:
  1. Finasteride: Antiandrogen, in hair follicle blocks 5α-reductase conversion of testosterone to intranuclearly active 5α-dihydrotestosterone (DHT):
     a. Use only with reliable contraception because DHT necessary for normal male fetus urogenital development
     b. Not FDA approved for treatment of hirsutism
     c. 1 to 5 mg PO qd
  2. Flutamide: Inhibits androgen uptake and receptor binding:
     a. Not recommended by Endocrine Society Clinical Practice Guidelines and not FDA approved for treatment of hirsutism, but used by some European endocrinologists
     b. Use only with reliable contraception
     c. Reserved for women with severe, resistant hirsutism because of risk of hepatic dysfunction
  3. Cyproterone acetate: Antiandrogen that competes with DHT for binding androgen receptors. Used as progestin component of OCPs outside the U.S.
- Other treatments directed at specific underlying etiology:
  1. Metformin/thiazolidinediones: Therapy reserved for documented insulin-resistant states
  2. GnRH agonists: Recommended only in women with severe hyperandrogenemia (e.g., ovarian hyperthecosis) with suboptimal response to combination low-dose estrogen/progestin pills and antiandrogen treatment. Inhibits gonadotropin and consequently ovarian androgen and estrogen secretion
  3. Dexamethasone: Adrenal glucocorticoid suppression is reserved for diagnosis of adrenal enzyme deficiency
  4. Total abdominal hysterectomy/bilateral salpingo-oophorectomy reserved for recalcitrant hirsutism in older female with hyperthecosis and undesired fertility

PEARLS & CONSIDERATIONS

COMMENTS

- Hirsutism is both an endocrine and cosmetic problem for patients.
- Ovulation induction therapy is indicated in women desiring pregnancy.
- Delay checking serum androgens until oral contraceptives have been discontinued for 2 to 3 mo.
- Evaluation of incidental adrenal mass is always warranted.

BASIC INFORMATION

DEFINITION

Langerhans cell histocytosis (LCH) is a clonal neoplastic proliferation of Langerhans-type dendritic cells that express CD1a, CD207, langerin, and S100 protein along with an accompanying inflammatory infiltrate. This leads to formation of granulomatous lesions (Box E1) that result in varying degrees of organ involvement and dysfunction (Table E1).

SYNONYMS

Eosinophilic granuloma (if solitary lesion)
Hand-Schüller-Christian disease (if multiple lesions)
LCH
Letterer-Siwe disease (if disseminated or visceral involvement)
Langerhans cell histiocytosis

ICD-10CM CODES

C96.0	Multifocal and multisystemic (disseminated) Langerhans-cell histiocytosis
C96.6	Unifocal Langerhans-cell histiocytosis
D76.3	Other histiocytosis syndromes
C96.5	Multifocal and unisystemic Langerhans-cell histiocytosis

EPIDEMIOLOGY & DEMOGRAPHICS

- Incidence is about 5 per million persons per yr, with most cases occurring in childhood.
- LCH is the most common histiocytic disorder.
- LCH affects males more often than females, with ratio of about 3.7:1.
- More common in whites of Northern European descent; rare in those of African descent.
- Disseminated LCH usually occurs before 2 yr of age.
- Primary Langerhans cell histocytosis of the lung is almost always a disease of smokers, usually nonclonal, and thought to represent a reactive process.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical presentation is highly variable.
- Patients with unifocal disease are usually older children and adults who most commonly present with a lytic bone lesion that is eroding the cortex of the bone (Fig. E1). Solitary lesion at other sites present as mass lesions or enlarged lymph nodes.
- Patients with unisystem multifocal disease (Hand-Schüller-Christian disease) are usually young children who present with multiple or sequential destructive bone lesions often associated with adjacent soft tissue masses. Skull and mandibular involvement is common. A benign isolated bony lesion (eosinophilic granuloma) is most often found in children younger than 15 yr of age.
- An aggressive disseminated disease infiltrating organs and causing organ dysfunction (Letterer-Siwe disease). This is the rarest form of LCH, affecting mostly children younger than 2 yr.
- Bone lesions (seen in about 80%):
  1. May be isolated or multiple
  2. Although some bone lesions may be asymptomatic, patients may complain of pain in the localized area of the bone
  3. The common sites of bone involved differ depending on the patient's age. In children, the most common bone involvement is the skull (~40%), followed by the femur, rib, vertebra, and humerus. In contrast, in adults, the primary sites of bone involvement are the jaw (30%), skull, vertebra, pelvis, and extremities
  4. Proptosis
  5. Mastoiditis
  6. Loose teeth
  7. Gingival hypertrophy
- Skin is involved in 40% of the patients (Fig. E2, Fig. E3), and common manifestations are brown to purplish papules or eczematous rash. Common sites: Scalp, neck, trunk, groin, and extremities. Cutaneous clues to Langerhans cell histiocytosis are summarized in Box E2.
- Lymphadenopathy is present in nearly 20% of patients. Cervical nodes are commonly involved. Involved lymph nodes are usually soft and matted on physical examination. Pulmonary disease is seen in approximately 10% of cases. More common in adults than in children. Patients with lung involvement may present with spontaneous pneumothorax or nonproductive cough, dyspnea, chest pain, or constitutional symptoms such as fever or weight loss. Diffuse emphysema associated with pulmonary fibrosis is the end stage of a mixed restrictive and obstructive pattern of disease.
- Liver involvement is seen in 15% to 20% of cases and presents as tumor-like or cystic lesions or as hepatomegaly. It can be accompanied by liver function abnormalities such as hyperbilirubinemia, elevated liver enzymes, or clotting factor deficiencies. Involvement of the biliary tree may present as progressive sclerosing cholangitis.
- Involvement of the spleen may present as massive splenomegaly (5% to 10%) with or without hypersplenism.
- Histocytosis X involves CNS in approximately 6% of the patients at the time of diagnosis. However, lesions of facial bone and those in the cranial fossa can have CNS involvement in approximately 25% of patients. The most common site affected is the hypothalamic-neurohypophyseal region, where infiltration and destruction usually manifest as diabetes insipidus, which manifests as insatiable thirst and urination. The other common CNS manifestations are symptoms of neurodegeneration (ataxia, cognitive dysfunction). Involvement of the thymus, parotid glands, and GI tract has been reported in rare cases.

ETIOLOGY

Historically, LCH has been presumed to arise from transformed or pathologically activated epidermal dendritic cells called Langerhans cells. New evidence suggests that LCH occurs as a consequence of misguided differentiation of myeloid dendritic cell precursors. Genetic, molecular, and functional data implicate activation of the ERK signaling pathway at critical stages in myeloid differentiation as an essential and universal driver of LCH pathology. A recent meta-review comprising 653 patient samples assessed an overall frequency of 48.5% for the *BRAF* V600E point mutation in LCH.

DIAGNOSIS

The diagnosis of LCH is made based on the biopsy of the involved organ. The key biopsy feature is identification of the LCH cells, which

BOX E1 Histiocytoses

Langerhans cell histiocytosis
Juvenile xanthogranuloma
Xanthoma disseminatum
Benign cephalic histiocytosis
Necrobiotic xanthogranuloma
Generalized eruptive histiocytoma
Progressive nodular histiocytoma
Indeterminate cell histiocytosis
Multicentric reticulohistiocytosis
Sinus histiocytosis with massive lymphadenopathy (Rosai–Dorfman disease)
Hemophagocytic syndromes
Malignant histiocytic syndromes

TABLE E1 Organ Involvement in Langerhans Cell Histiocytosis

Organ	Comment
Skin	Often the initial presenting sign
Bone	Painful swelling common; incidence: Skull > long bones > flat bones (ribs, pelvis, vertebrae)
Lymph nodes	Cervical most common
Liver	
Spleen	
Lungs	Diffuse micronodular pattern on radiography
Gastrointestinal tract	
Thymus	
Bone marrow	Pancytopenia portends a poor prognosis
Gingivae, buccal mucosa	Swelling, erythema, erosions, petechiae
Kidney	
Endocrine glands	Diabetes insipidus most common
Central nervous system

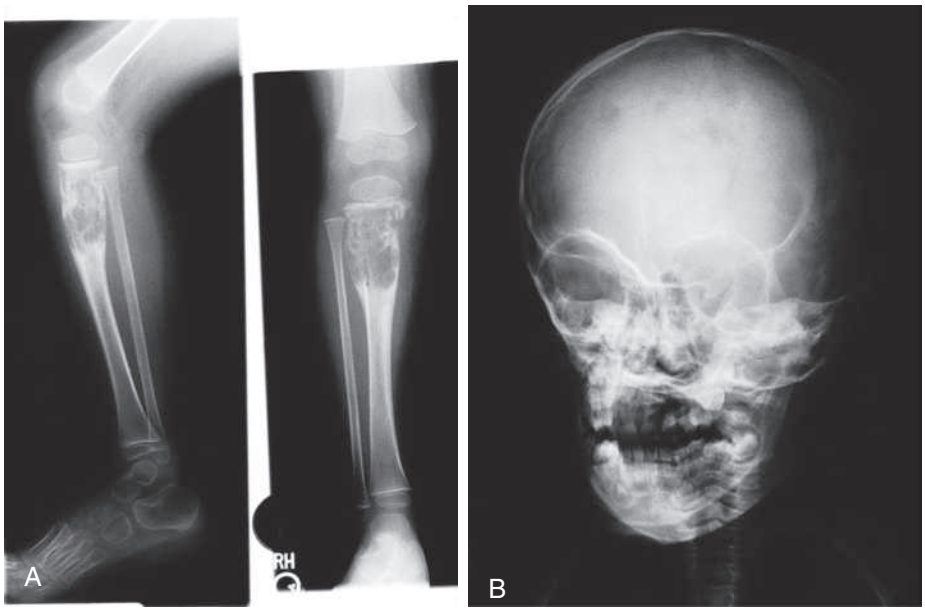

FIG. E1 Langerhans cell histiocytosis. Plain radiography reveals multiple lytic lesions in the tibia **(A)** and the skull **(B)** of a 4-yr-old child with disseminated disease. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

FIG. E2 Langerhans cell histiocytosis (LCH). Erythematous, crusted papules on the palm in this newborn with congenital multisystem LCH. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

FIG. E3 Neonatal Langerhans cell histiocytosis (LCH). These crusted, vesicular lesions were initially felt to be suggestive of neonatal varicella in this 10-day-old female. Biopsy confirmed LCH. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.)

BOX E2 Cutaneous Clues to Langerhans Cell Histiocytosis

Recalcitrant seborrheic dermatitis-like eruption
Localization of rash to scalp, posterior auricular regions, perineum, axillae
Eroded papules in flexural areas
Petechial or purpuric papules
Crusted papules on palms and/or soles (scabies preparation negative)
Any of the above lesions in combination with lymphadenopathy

From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, Philadelphia, 2016, Elsevier.

TABLE E2 Distinguishing Characteristics of the Reactive Lymphohistiocytoses

	Genetic History	Virus Infection	Cellular Immune Function	Miscellaneous
HLH, genetic	Autosomal recessive	Possibly associated	↓ CMI ↓ NK cell activity ↓ Monocyte killing ↓ CMI	Perforin deficiency Hypertriglyceridemia, perforin (PRF1), Munc 13-4 mutations
Secondary infection–associated	Sporadic	Yes	↓ CMI NL or ↑ NK cell in instances associated with EBV ↓ Anomalous EBV-related killing	Coagulopathy early in the course of the disease
XLP	X-linked sporadic	EBV	NL or ↑ NK cell NL or ↑ anomalous EBV-related killing	*SH2DIA* mutation Severe, often fatal hepatitis
SHML	Sporadic	?EBV	Not reported	Autoimmune phenomena
LG	Sporadic	EBV	↓ CMI	Lymphoma development

CMI, Cell-mediated immunity; *EBV,* Epstein-Barr virus; *HLH,* hemophagocytic lymphohistiocytosis; *LG,* lymphomatoid granulomatosis: *NK,* natural killer; *NL,* normal; *SHML,* sinus histiocytosis with massive lymphadenopathy; *XLP,* X-linked lymphoproliferative syndrome.

From Nathan DG et al [eds]: *Nathan and Oski's hematology of infancy and childhood,* ed 6, Philadelphia, 2003, WB Saunders.

are oval with grooved, folded, indented, or lobulated nuclei with fine chromatin, inconspicuous nucleoli, and thin nuclear membranes. The characteristic milieu includes a variable number of eosinophils, histiocytes, neutrophils, and small lymphocytes. Occasionally, eosinophilic abscesses with central necrosis, rich in Charcot-Leyden crystals, may be found. The ultrastructure hallmark is the cytoplasmic Birbeck granules. Langerhans cells consistently express CD1a, CD207, langerin, and S100 protein.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of LCH is extensive because it is an uncommon disease that can affect multiple organ systems. LCH in bone, lymph nodes, thymus, and spleen can be confused with lymphoma, solid tumors, or CNS tumors, including germinoma and meningioma. Cutaneous involvement can mimic vasculitis and cutaneous lymphoma, and pulmonary involvement can mimic multiple diseases that cause interstitial lung disease. Histologically and immunophenotypically, LCH must be distinguished from other histiocytic and dendritic cell disorders, metastatic solid or hematopoietic neoplasms, and hemophagocytic lymphohistiocytic and macrophage activation syndromes. The common differential diagnoses are:

1. Erdheim Chester disease (ECD): Rare multisystem histiocytic disorder seen in adults.
2. Juvenile xanthogranuloma: Benign proliferative disorder of the histiocytic cells of the dermal dendrocytic phenotype.
3. Multiple myeloma.
4. Hemophagocytic lymphohistiocytiosis (HLH): HLH and related macrophage activation syndrome are systemic disorders with tissue infiltration by nonneoplastic histocytes.
5. Rosai Dorfman disease: A disease characterized by sinus histiocytosis with massive lymphadenopathy.

Histiocytosis syndromes of childhood are three classes based on histopathologic findings. Class I histiocytosis (also known as LCH) includes the clinical entities of eosinophilic granuloma, Hand-Schüller-Christian disease, and Letterer-Siwe disease. Class II histiocytoses are nonmalignant proliferative disorders that are characterized by accumulation of macrophages. The two major diseases among the class II histiocytoses are hemophagocytic lymphohistiocytosis (FHLH) and infection-associated hemophagocytic syndrome (IAHS). These diseases are grouped together under the term *hemophagocytic lymphohistiocytosis* (HLH) (see Table E2). Class III histiocytoses are malignancies of cells of monotype-macrophage lineage (acute monocytic leukemia) and true malignant histiocytoses.

WORKUP

Baseline evaluation should include:

- Routine laboratory tests: CBC with differentials, chemistries with liver and renal functions, ESR, LDH, ferritin, uric acid, and urinalysis.
- Unilateral bone marrow aspiration and biopsy is indicated in patients with liver and spleen involvement, for patients with unexplained cytopenias, and for children younger than 2 yr of age.
- *BRAF* V600E mutation testing. This mutation is positive in about 65% of the pathologic dendritic cells.
- Radiographic evaluation should include a skeletal survey, skull series, bone scan, and chest radiograph. PET scan is also helpful in measuring the initial extent of disease.
- Other laboratory testing or radiologic imaging should be done depending on the symptoms and laboratory abnormalities.

LABORATORY TESTS

- CBC may reveal cytopenias in patients with bone marrow involvement or those with hypersplenism.
- Electrolytes, BUN, creatinine, urinalysis, and urine and serum osmolality are helpful in the diagnosis of diabetes insipidus.
- Results of liver function tests (LFTs) may be abnormal in patients with liver involvement.
- Bronchoalveolar lavage may show increased numbers of CD1a-positive histiocytes or Langerhans cells in patients with pulmonary LCH.

IMAGING STUDIES

- Radiograph studies of affected areas show lytic lesions with or without sclerotic margins.
- Panoramic dental view of the mandible and maxilla for children with oral involvement.
- Chest radiograph can show interstitial reticulonodular infiltrates. This pattern typically progresses toward frank honeycombing fibrosis later in the course of the disease (Fig. E4).
- High-resolution CT scan of the chest confirms interstitial lung scarring, nodules, and cysts and represents an excellent noninvasive means for diagnosis and follow-up of pulmonary LCH. Pulmonary cysts are bilateral and symmetric, showing slight upper-lobe predominance with relative sparing of the costophrenic angles.
- CT scan of the temporal bone is indicated for evaluation of mastoid and inner and middle ear involvement.
- Ultrasound of the abdomen is helpful for evaluation of hepatosplenomegaly.
- Conventional cholangiography or MRI cholangiopancreatography can confirm the presence of biliary involvement.
- MRI of the brain is indicated to visualize the hypothalamic-hypophyseal region in patients suspected of having diabetes insipidus.

Rx TREATMENT

Treatment is based on organ involvement and the extent of disease. LCH is usually stratified into single or multisystem LCH based on the organ system involvement. Single-system LCH patients typically do not have systemic symptoms. Multisystem LCH have two or more organ or system involvement.

- Single-system disease:
  Patients with truly limited single-site disease such as skin or bone may not need upfront intervention. The commonly available topical therapies for single organ or system involvement are as follows:
  1. Isolated bone lesions:
     a. Curettage of affected site and implantation of allograft bone chips or polymethylmethacrylate
     b. Intralesional prednisone
     c. Bisphosphonates
     d. NSAIDs
     e. Radiation therapy is useful for vertebrae or femoral neck lesions at risk of collapse
  2. Single skin lesions are treated with:
     a. Topical steroid (e.g., triamcinolone acetonide) applied bid
     b. Nitrogen mustard in 20% solution
     c. Surgery
     d. Intralesional interferon
     e. Isotretinoin

FIG. E4 Langerhans cell histiocytosis (LCH; histiocytosis X). There is a reticular nodular pattern in the upper lobes. The lung volumes are preserved.

3. Treatment of solitary lymph node involvement:
   a. Excision at the time of diagnosis
   b. Systemic oral prednisone

- Multisystem disease:
  Treatment of multisystem disease includes systemic chemotherapy (vinblastine and prednisone with mercaptopurine added for high-risk patients). Typically induction therapy is given for 6 wk, and if there is a response to therapy, the therapy is continued for a total of 1 yr. Patients with multisystem disease and risk of organ involvement (i.e., liver, spleen, and bone marrow) seem to benefit from combination chemotherapy regimens. Approximately 50% of patients fail to respond to standard systemic chemotherapy, justifying continued need for clinical trials.
  1. For severe, high-risk, disseminated cases not responding within 6 wk of initial treatment, salvage therapy, including high dose of the purine analogue cladribine along with high-dose cytosine arabinoside followed by allogeneic blood stem cell transplantation, should be considered. Additionally, liver or lung transplantation might be the treatment of choice for terminal liver and lung failure patients.
  2. Targeted therapy using vemurafenib has resulted in clinical responses in the majority of cases with the BRAF mutation.
  3. Diabetes insipidus is treated with DDAVP.
  4. Adults with isolated pulmonary LCH do not require aggressive treatment and benefit from smoking cessation.
  5. Empirical steroids, in either short pulses or longer exposures, has been used in the treatment of pulmonary disease; however, data regarding effectiveness are limited.
  6. Lung transplantation has been tried in both children and adults with advanced pulmonary disease and limited lung function, but failure rates are high because of local recurrence after transplantation.

PROGNOSIS & PREDICTIVE FACTORS

- Clinical course is related to staging of the disease at presentation, with 99% or greater survival for unifocal disease and 66% mortality for younger children with multisystem involvement who do not respond promptly to therapy.
- Involvement of bone marrow, liver, and lung are regarded as high-risk factors.
- Progression from initial focal disease to multisystem involvement can occur, most commonly in infants.
- Systemic and (rarely) multifocal disease can be complicated by hemophagocytic syndrome.

REFERRAL

Multidisciplinary approach: Pediatric oncologist, radiation oncologists, oral maxillary surgeons, ear-nose-throat specialists, audiology, dermatology, endocrinology, and family counseling

PEARLS & CONSIDERATIONS

COMMENTS

- The course of LCH is often unpredictable and varies from spontaneous resolution to rapid progression and death or multiple recurrences and regressions with risk for permanent sequelae.
- The association of LCH with other malignancies (e.g., acute lymphocytic leukemia, acute myeloid leukemia, and solid tumors) has been cited.

PATIENT & FAMILY EDUCATION

- Instruct patients to promptly report the development of hemoptysis. This symptom may indicate malignancy or superimposed bacterial–fungal infection, such as *Aspergillus* species infection.
- Educate about the likely etiologic role of cigarette smoking.

BASIC INFORMATION

DEFINITION

Histoplasmosis is caused by the fungus *Histoplasma capsulatum* and characterized by a primary pulmonary focus with occasional progression to chronic pulmonary histoplasmosis (CPH) or various forms of dissemination. Progressive disseminated histoplasmosis (PDH) may present with a diverse clinical spectrum, including adrenal necrosis, pulmonary and mediastinal fibrosis, and ulcerations of the oropharynx and GI tract. In those patients coinfected with HIV, it is a defining disease for AIDS.

SYNONYMS

- North American histoplasmosis
- Ohio Valley fever
- Vanderbilt disease

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Unknown for acute pulmonary disease
- For CPH, estimated at 1/100,000 cases in endemic areas
- For PDH in immunocompetent adults, estimated at 1/2000 cases of histoplasmosis

PREVALENCE: Unknown

PREDOMINANT SEX: Clinically evident disease is most common in males; male:female ratio of 4:1

PREDOMINANT AGE:

- CPH is most often seen in males >50 yr old with an associated history of COPD.
- Presumed ocular histoplasmosis syndrome (POHS) is seen between ages of 20 and 40 yr.

PEAK INCIDENCE: Unknown

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Conidia are deposited in alveoli then converted to yeast forms where they spread to regional lymph nodes and other organs, especially liver and spleen.
- 1 to 2 wk later, a granulomatous inflammatory response begins to contain the yeast in the form of discrete granulomas.
- Delayed-type hypersensitivity to *Histoplasma* antigens occurs 3 to 6 wk after exposure.
- Clinical disease manifests in various forms (Box E1), depending on host cellular immunity and inoculum size:
  1. **Acute primary pulmonary histoplasmosis:**
     a. An overwhelming number of patients are asymptomatic.
     b. Most clinically apparent infections manifest by complaints of fever, headache, malaise, pleuritic chest pain, nonproductive cough, and weight loss.
     c. Less than 10%, mainly women, complain of arthralgias, myalgias, and skin manifestations such as erythema multiforme or erythema nodosum (Fig. E1).
     d. Acute pericarditis presents in a smaller percentage of patients.
     e. Hepatosplenomegaly is most commonly observed in children.
     f. With particularly heavy exposure, there is severe dyspnea, marked hypoxemia, impending respiratory failure.
     g. Most patients are asymptomatic within 6 wk.
  2. **CPH:**
     a. Presents insidiously with low-grade fever, malaise, weight loss, cough, sometimes with blood-streaked sputum or frank hemoptysis.
     b. Most patients with cavitary lesions present with associated COPD or chronic bronchitis, masking underlying fungal disease.

BOX E1 Clinical Manifestations of Histoplasmosis

- Asymptomatic infection
- Pneumonia
- Progressive disseminated infection (HIV, immunocompromise, infancy)
- Mediastinal lymphadenopathy
- Cavitary pneumonia[a]
- Asthma-like illness
- Pleural effusion or granulomatous pleuritis[a]
- Obstruction or dysfunction of contiguous mediastinal structures (bronchi, esophagus) by granulomatous inflammation of lymph nodes (mediastinal granuloma)
- Isolated cervical or supraclavicular lymphadenopathy[a]
- Superior vena cava syndrome[a]
- Mediastinal fibrosis[a]
- Vocal cord granuloma
- Vocal cord paralysis
- Hemoptysis
- Broncholithiasis with lithoptysis[a]
- Chylothorax[a]
- Diaphragmatic weakness or paralysis
- Esophageal diverticulum or fistula
- Pericarditis
- Erythema nodosum
- Meningitis or focal cerebritis[a]
- Arthritis or arthralgias
- Parotitis
- Nephrocalcinosis
- Interstitial nephritis[a]
- Hypercalcemia
- Gastrointestinal tract ulceration or hemorrhage
- Gastrointestinal tract pseudomalignancy
- Crohn disease–like illness
- Biliary obstruction[a]
- Ocular histoplasmosis, choroiditis[a]
- Endocarditis[a]
- Adrenal mass[a]

[a]Rare in children.

FIG. E1 Erythema nodosum in an adolescent boy with pulmonary histoplasmosis. (From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.)

c. Tends to worsen preexisting pulmonary disease and further contribute to eventual respiratory insufficiency.

3. **PDH:**
   a. In both acute and subacute forms, constitutional symptoms of fever, fatigue, malaise, and weight loss are common.
   b. Acute form (seen in infants and children) presents with respiratory symptoms, fever ≥101° F(38.3° C), generalized lymphadenopathy, marked hepatosplenomegaly, and fulminant course resembling septic shock associated with a high fatality rate.
   c. Subacute form is more common in adults and associated with lower temperatures, hepatosplenomegaly, oropharyngeal ulceration, focal organ involvement (including adrenal destruction, endocarditis, chronic meningitis, and intracerebral mass lesions).
   d. Course of subacute form is relentless, with untreated patients dying within 2 yr.
   e. Chronic PDH is found in adults and marked by gradual symptoms of weight loss, weakness, easy fatigability; low-grade fever when present; oropharyngeal ulcerations and hepatomegaly and/or splenomegaly in one third of patients.
   f. Less clinical evidence of focal organ involvement in chronic form than in subacute form.
   g. Natural history of chronic form is protracted and intermittent, spanning mos to yrs.

- **Histoplasmoma:**
  1. A healed area of caseation necrosis surrounded by a fibrous capsule
  2. Usually asymptomatic
- **Mediastinal fibrosis:**
  1. A rare consequence of a fibroblastic process that encases caseating mediastinal lymph nodes producing severe retraction, compression, and distortion of mediastinal structures
  2. Constriction of the bronchi resulting in bronchiectasis, also esophageal stenosis associated with dysphagia, and superior vena cava syndrome
- **POHS:**
  1. Diagnosis characterized by distinct clinical features, including atrophic choroidal scars and maculopathy in patients with histories suggestive of exposure to the fungus (e.g., residence in an endemic area)
  2. Patient complains of distortion or loss of central vision without pain, redness, or photophobia
  3. Usually no evidence of infection except for a positive skin reaction to histoplasmin
- **In patients with AIDS:**
  1. Possible presentation as overwhelming infection similar to acute PDH seen in children
  2. Constitutional symptoms: Fever, weight loss, malaise, cough, dyspnea
  3. About 10% with cutaneous maculopapular, erythematous eruptions or purpuric lesions on face, trunk, and extremities
  4. Up to 20% with CNS involvement, manifesting as intracerebral mass lesions, chronic meningitis, or encephalopathy

ETIOLOGY

- *H. capsulatum* is a dimorphic fungus present in temperate zones and river valleys worldwide.
- In the U.S., it is highly endemic in southeastern, mid-Atlantic, and central states (Ohio and Mississippi River valleys). Outside the U.S. it is distributed in Central and South America, the Caribbean, and in regions of Australia, India, and Africa.
- Exists as mold at ambient temperature and favors soils enriched with bird or bat droppings.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute pulmonary histoplasmosis:
  1. Mycobacterium tuberculosis
  2. Community-acquired pneumonias caused by *Mycoplasma* and *Chlamydia*
  3. Other fungal diseases, such as those caused by *Blastomyces dermatitidis* and *Coccidioides immitis*
- Chronic cavitary pulmonary histoplasmosis: *M. tuberculosis*
- Histoplasmomas: True neoplasms
- Sarcoidosis

WORKUP

- Suspect diagnosis in patients who present with a history of residence or travel in an endemic area, especially if engaged in occupations (e.g., outside construction or street cleaning) or hobbies (e.g., cave exploring) that increase the likelihood of exposure to fungal spores.
- Suspect diagnosis in immunosuppressed patients with remote history of exposure, especially if associated with characteristic calcifications on chest x-ray.

LABORATORY TESTS

- Detection of *Histoplasma* antigen in serum and urine. Urine antigen is 75% accurate in normal hosts and 95% in immunocompromised patients with disseminated disease. The sensitivity and specificity of the urinary antigen is also dependent on the stage of infection exceeding 80% in acute and disseminated infection but decreasing to less than 50% in chronic infection. The serum test is close to 100% accurate, but with *Blastomyces* and *Coccidioides*, tests may cross-react with infections. Tests can also be performed on bronchoalveolar lavage.
- Demonstration of organism on culture from body fluid or tissues biopsy (Fig. E2) will confirm the diagnosis in clinically suspected cases and negative urinary antigen.
  1. Especially high yield in patients with AIDS
  2. Characteristic oval yeast cells in neutrophils with Giemsa stain from peripheral smear
  3. Preparations of infected tissue with Gomori silver methenamine for revealing yeast forms, especially in areas of caseation necrosis
- Serologic tests, including complement-fixing (CF) antibodies and immunodiffusion assays.
- In PDH:
  1. Pancytopenia
  2. Marked elevations in alkaline phosphatase and alanine aminotransferase (ALT) common
- In chronic meningitis (majority of cases):
  1. CSF pleocytosis with either lymphocytes or neutrophils predominating
  2. Elevated CSF protein levels
  3. Hypoglycorrhachia

IMAGING STUDIES

- Chest x-ray in acute pulmonary histoplasmosis:
  1. Singular or multiple patchy infiltrates, especially in the lower lung fields
  2. Hilar or mediastinal lymphadenopathy with or without pneumonitis
  3. Diffuse nodular or confluent bilateral miliary infiltrates characteristic of heavier exposure
  4. Infrequent pleural effusions, except when associated with pericarditis
- Chest x-ray in histoplasmoma: Coin lesion displaying central calcification, ranging from 1 to 4 cm in diameter, predominantly located in the subpleural regions
- Chest x-ray in CPH (Fig. E3):
  1. Upper lobe disease frequently associated with cavities

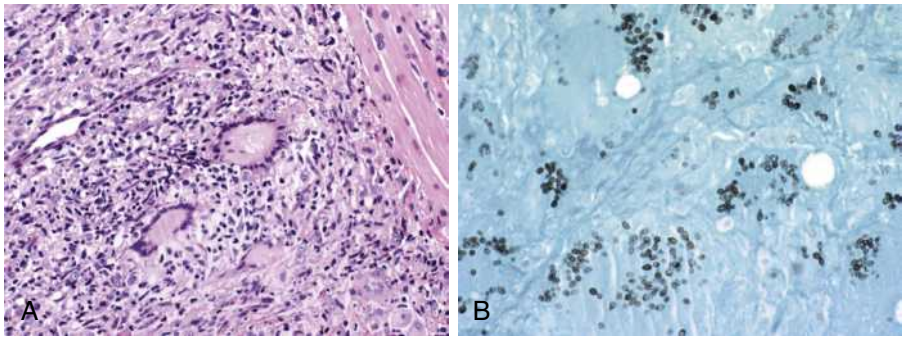

FIG. E2 A, Photomicrograph shows a tissue biopsy specimen from a patient with slowly progressing disseminated histoplasmosis. Granulomas are well formed, and no organisms are seen. Hematoxylin and eosin stain, ×450. **B,** Special stains better demonstrate yeast in tissue sections. Silver methenamine stain, ×450. (From Mason RJ: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, WB Saunders.)

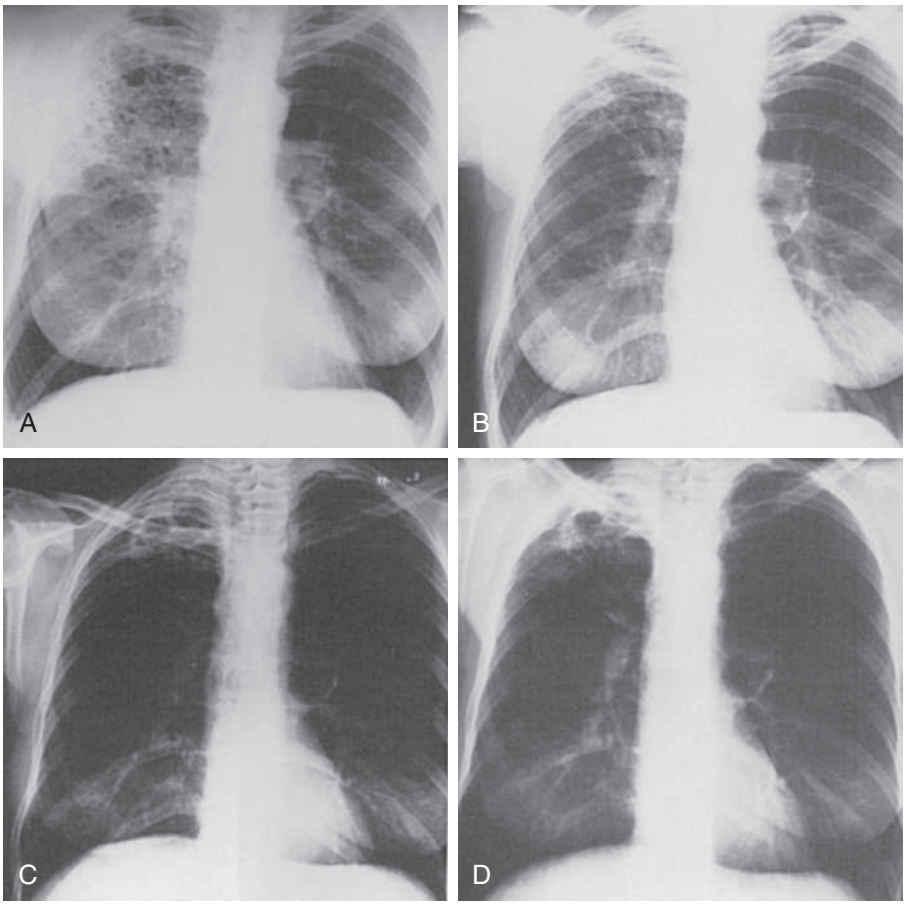

FIG. E3 The evolution of chronic pulmonary histoplasmosis in a smoker. A, At the onset of the illness, the chest radiograph shows multiple cavity-like air spaces. **B,** 2.5 yr later, fibrosis has occurred with volume loss of the lobe and retraction of the hilum. **C,** A further 17 mo later, the entire right upper lobe appears to be destroyed. **D,** There are signs of continued activity and a residual cavity at the time of diagnosis. The sputum culture was positive for *Histoplasma capsulatum*. (From Mason RJ: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, WB Saunders.)

2. Preexisting calcifications in the hilum associated with peribronchial streaking extending to the parenchyma
- Chest x-ray in acute PDH: Hilar adenopathy and/or diffuse nodular infiltrates
- CT scan of adrenals to reveal bilateral enlargement and low-attenuation centers

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

For life-threatening disease seen in acute disseminated disease or infection in patients with AIDS: Supportive therapy with IV fluids

ACUTE GENERAL Rx

- No drug therapy is required for asymptomatic pulmonary disease.
- A course of therapy with itraconazole 200 mg PO tid for 3 days, then 200 mg/day PO for 6 to 12 wk may be beneficial in some patients with acute pulmonary distress. Avoid fluconazole because it is not as active.
- Same therapy appropriate for immunocompetent, mild to moderately symptomatic patients with CPH and subacute and chronic forms of PDH, but duration for 6 to 12 mo.
- Use amphotericin B 0.7 to 1 mg/kg IV q day for initial therapy in moderate to severe disease and then transition to oral itraconazole within 1 to 2 wk. Lipid formulations of amphotericin can be used to avoid nephrotoxicity of amphotericin B, and they produce better outcomes in terms of mortality, rates of culture conversion, and side effects.
- Liposomal amphotericin: 3 mg/kg/day IV or amphotericin B lipid complex: 5 mg/kg/day.
- Posaconazole is highly effective as well, but voriconazole is less active in vitro than itraconazole and posaconazole. Isavuconazole is also active in vitro, but echinocandins such as micafungin are not effective.
- Chronic cavitary pulmonary histoplasmosis: Itraconazole 200 mg PO tid for 3 days, then once or twice daily for at least 12 mo.
- CNS histoplasmosis: Liposomal amphotericin B, 5 mg/kg/day for a total of 175 mg/kg over 4 to 6 wk, then itraconazole 200 mg 2 to 3×/day for at least 12 mo.
- Endocarditis: Surgical treatment with excision of infected valve or graft combined with amphotericin for a total dose of 35 mg/kg or 2.5 g.
- For pericardial disease:
  1. Antifungal therapy: No apparent benefit
  2. Best managed with NSAIDs
- For POHS:
  1. Antifungal therapy: No apparent benefit
  2. May respond to laser therapy

CHRONIC Rx

- In patients with AIDS: Lifelong suppressive therapy with either itraconazole, given 200 mg PO q day, or IV amphotericin B at a dose of 50 mg once weekly; a triazole compound posaconazole (400 mg PO bid) may be useful in refractory cases, but clinical experience is limited at this point
- Prophylaxis in HIV-infected patients with <150 CD4 cells/mm^3: Itraconazole 200 mg PO qd

DISPOSITION

For those with chronic or progressive disease, especially if immunocompromised, prognosis is dependent on prompt recognition and timely administration of appropriate antifungal drugs.

REFERRAL

- To an infectious disease specialist in suspected cases of disseminated disease, especially if immunocompromised
- To a pulmonologist for patients with CPH form because of progressive respiratory compromise
- To a thoracic surgeon for decompression procedures for progressive mediastinal fibrosis

PEARLS & CONSIDERATIONS

- *H. capsulatum*, variety *duboisii*, also known as African histoplasmosis, is restricted to Senegal, Nigeria, Zaire, and Uganda.
- Unlike *H. capsulatum*, pulmonary forms of *duboisii* are not seen, and the disease is limited to the skin, soft tissues, and bone.

COMMENTS

- Patients living in endemic areas, especially if immunocompromised, should take appropriate respiratory precautions when disposing of bird waste from rooftop or home aviaries.
- Appropriate respiratory precautions should also be taken when leisure traveling to areas that act as a natural haven for the fungus, such as bat caves.

BASIC INFORMATION

DEFINITION

Patients with histrionic personality disorder (HPD) present with a pervasive pattern of excessive emotionality and attention-seeking behavior that generally begins in early adulthood. The individual must meet five or more of the following criteria:

1. Is uncomfortable in situations where he or she is not the center of attention
2. Interaction with others is often characterized by inappropriate sexually seductive or provocative behavior
3. Displays rapidly shifting and shallow expression of emotions
4. Consistently uses physical appearance to draw attention to self
5. Has a style of speech that is excessively impressionistic and lacking in detail
6. Shows self-dramatization, theatricality, and exaggerated expression of emotion
7. Is suggestible (i.e., easily influenced by others or circumstances)
8. Considers relationships to be more intimate than they actually are

SYNONYMS

Hysterical personality disorder
Psycho-infantile personality disorder
Personality disorder (nonspecific)
Personality disorder (trait specified)

ICD-10CM CODE	
F60.4	Histrionic personality disorder
DSM-5 CODE	
301.5	Histrionic personality disorder

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE (IN U.S.):

- Diagnosed more often in women (85%); rarely found in men
- Prevalence: 1% to 3%

PREDOMINANT SEX: Female. Cultural factors (e.g., attention-seeking behavior not as acceptable in men) may lead to more common diagnosis in women.

PREDOMINANT AGE: Generally begins in early adulthood.

GENETICS: Limited research using interview and self-report methods suggests that histrionic personality disorder has a moderate genetic component.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- No specific physical findings
- Exaggerated emotionality
- Clinical presentation:
  1. Exaggerated, shallow, and/or rapidly shifting emotions
  2. A pattern of repeated attention-seeking behavior, often suggestive or provocative
  3. Theatrical

ETIOLOGY

- Unknown
- Hypothesized that childhood events, psychosocial adversity, and genetics are contributory
- A two-generation study by Cloninger and Guze (1975), showed that the daughters of fathers with sociopathy had a higher prevalence of hysteria than did daughters of other fathers. The differences were significant both for daughters with hysteria comorbid with sociopathy and for daughters with hysteria alone

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other cluster B personality disorders (narcissistic, borderline personality disorder especially hysteroid dysphoria, antisocial personality disorder) share some common features
- Other personality disorders (e.g., dependent personality disorder)
- Personality change attributable to general medical condition
- Symptoms in association with chronic substance abuse

WORKUP

There is no formal test to establish diagnosis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Long-term individual psychotherapy is treatment of choice.
- One controlled study exists, suggesting that patients in schema therapy experience greater functional improvement and symptom reduction compared with treatment-as-usual and clarification-oriented psychotherapy.
- Unlike other people who have personality disorders, these individuals often seek treatment and exaggerate their symptoms and difficulties in functioning.
- Patients tend to be more emotionally needy and are often reluctant to terminate therapy.

ACUTE GENERAL Rx

- No placebo-controlled trials.
- Impulsive-aggressive variants can occasionally benefit from selective serotonin reuptake inhibitor (SSRI) antidepressants.
- Care should be given when prescribing medications because of the potential for self-destructive or otherwise harmful behaviors.

DISPOSITION

- Therapeutic approaches should not focus on the long-term personality change but rather short-term alleviation of specific difficulties and deficits within the person's life.
- Therapeutic approaches that emphasize vague somatic, anxious, or depressive symptoms often fail.
- Patients are likely to be intolerant or drop out of treatment approaches that use delayed gratification.
- Symptoms are moderately stable over adulthood and may remit or decrease in intensity with age.

REFERRAL

Primarily treated by mental health professionals

PEARLS & CONSIDERATIONS

- This disorder is difficult to treat.
- Like most personality disorders, patients present for treatment primarily when stress or other situational factors within their lives have made their ability to function and cope effectively impossible.
- Suicidality and risk of self-injury should be assessed on a regular basis, and suicidal threats and self-mutilation should not be ignored or dismissed. Patients may present with a higher risk for (or history of) suicidal gestures.
- Patients may report high rates of impulsive behavior motivated by sensation- or novelty-seeking.
- An alternative model in DSM-5, section III, reconceptualizes histrionic personality disorder as "Personality Disorder, Trait Specified," which rates (1) impairment in personality functioning (identity, self-direction, empathy, and/or intimacy) and (2) pathologic trait domains such as attention seeking, grandiosity, and manipulativeness.

PATIENT & FAMILY EDUCATION

Group and family therapy approaches are generally not recommended because individuals with this disorder often try to draw attention to themselves and exaggerate every action and reaction.

BASIC INFORMATION

DEFINITION

HIV-associated cardiomyopathy (HIVAC) encompasses several distinct types of heart failure with different etiologies. Before widespread use of antiretroviral therapy (ART), HIVAC manifested as symptomatic systolic dysfunction, with or without ventricular dilatation, in patients with end-stage AIDS. This condition is now mostly seen in regions where patients do not have easy access to ART. It is considered a Stage IV HIV-defining illness and indicates a poor prognosis. With the use of ART, the definition of HIVAC is evolving and includes a growing prevalence of diastolic dysfunction in asymptomatic individuals with adequate viral suppression.

SYNONYM

HIVAC

ICD-10CM CODES

I42.9 Cardiomyopathy, unspecified
B20 Human immunodeficiency disease

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE & PREVALANCE:

- The rate of systolic heart failure increases with decreasing CD4 counts and is especially prevalent with CD4 counts of less than 100 cells/mm^3. Before the use of ART, studies indicate that up to two thirds of AIDS patients had myocarditis on autopsy and half of all hospitalized patients with HIV had cardiomyopathy.
- In sub-Saharan Africa, 2.6% of all patients presenting to the hospital with decompensated heart failure have HIVAC. The mortality from HIVAC in some of these areas is as high as 15% to 20%.
- In high-income countries, the use of ART has decreased the risk of systolic dysfunction significantly to less than 10%. Conversely, the rate of subclinical diastolic dysfunction has increased to more than 40%.
- Risk factors include high viral load, low CD4 count, low selenium count, increased duration of HIV infection, and low socioeconomic status.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients typically present with new-onset heart failure in the setting of late-stage HIV. They display classic features of heart failure, including respiratory distress from pulmonary edema.
- Patients who are treated with ART may develop signs and occasional symptoms of subclinical cardiac dysfunction, whether systolic or diastolic. They can have abnormal ventricular filling, pulmonary hypertension, and decreased exercise capacity.

ETIOLOGY

There are multiple etiologies of systolic dysfunction in HIV patients. These include:

- Direct cardiotoxic effects of HIV infection causing cardiomyocyte apoptosis and myocardial infiltration with macrophages, starting as early as the acute phase of HIV infection
- Myocarditis via opportunistic infections, both viral and nonviral, including tuberculous myopericarditis, or toxoplasma and cryptococcal myocarditis
- Cardiac autoimmunity with HIV infection leading to increased risk for coronary artery disease
- Micronutrient deficiency, particularly of selenium, due to malnutrition and HIV wasting
- Zidovudine therapy, which causes myocardial damage through pathologic changes in mitochondria, an effect that is dose dependent and reversible on discontinuation of this medication:
  1. Note that there is a high prevalence of zidovudine use in low-income countries due to economic constraints, despite the availability of other, less cardiotoxic ART regimens.
- Many antiretroviral medications cause myocardial fibrosis and steatosis, which may impair contractility and lessen ventricular compliance
- An increased risk of ischemic cardiomyopathy

The diastolic dysfunction more prevalent in high-income countries is most likely due to a combination of chronic inflammation and the use of ART.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Ischemic cardiomyopathy: Patients receiving ART have an increased risk for atherosclerotic disease because of metabolic syndrome, likely caused by many HIV medications and greater life expectancy.

WORKUP

- Echocardiogram is the only test used to diagnose HIV-associated cardiomyopathy.
- There is currently no routine screening that is recommended.

TREATMENT

- Management is essentially the same as that for other cardiomyopathies. The treatment for acute decompensated heart failure is diuresis. Long-term care of systolic dysfunction would require the use of beta-blockers and ACEi/ARBs, as tolerated, to prevent progression of disease.
- ART should be started immediately in diagnosed individuals, despite the risk of cardiotoxicity from these medications.
- If a patient is already on ART, which includes zidovudine, changing ART regimen could be considered, as the cardiotoxic effects of this medication may be reversible.
- For end-stage heart failure, mechanical assist devices or cardiac transplant are options, although less available to HIV-infected individuals.

DISPOSITION & REFERRAL

- Infectious disease specialist: Referral to ensure treatment with the most appropriate ART regimen
- Cardiology: As with other forms of cardiomyopathy, depending on the degree of heart failure

PEARLS & CONSIDERATIONS

- Management of patients with HIV-associated cardiomyopathy should prioritize identification and correction of other concomitant causes of cardiomyopathy that may require specific therapies, including opportunistic infections, cardiotoxic drugs, and CAD.
- Left ventricular function is an independent predictor of death in adults infected with HIV.

BASIC INFORMATION

DEFINITION

- HIV-associated cognitive dysfunction covers a spectrum of disorders ranging from asymptomatic (asymptomatic neurocognitive impairment) to mild (mild neurocognitive disorder) to severe (including HIV-associated dementia).
- Cognitive, motor, and behavioral abnormalities.

SYNONYMS

HAD
HAND
HIV-associated neurocognitive disorder (HAND)
HIV dementia
HIV-associated dementia
Mild neurocognitive disorder
AIDS dementia complex
HIV-1 encephalopathy

ICD-10CM CODES

B20	Human immunodeficiency virus [HIV] disease
R41.8	Other and unspecified symptoms and signs involving cognitive functions and awareness
B97.35	Human immunodeficiency virus, type 2 [HIV 2] as the cause of diseases classified elsewhere

EPIDEMIOLOGY

- According to the CHARTER study, approximately 52% of HIV-infected individuals have HAND. The largest group has asymptomatic neurocognitive impairment (approximately 33%), followed by minor neurocognitive disorder (12%), and HIV-associated dementia (2%).
- The epidemiology has changed in the era of antiretroviral therapy (ART), with the number of cases of HIV-associated dementia (HAD) falling from 15% in the pre-ART era to 2% now, but the proportion of mildly affected patients is increasing.
- As HIV-infected patients live longer, the prevalence of HAND may be increasing.

CLINICAL FEATURES

- The 2007 Frascati Criteria for HAND require assessment of five cognitive domains: Verbal/language ability, attention and working memory, abstraction and executive function, speed of information processing, sensory perceptual skills, and motor skills. The criteria define three levels of HAND:
  1. Asymptomatic neurocognitive disorder: An acquired impairment in at least two cognitive domains as defined by a performance on neuropsychological testing of more than 1 SD below expected age and education-adjusted norms. This impairment does not impact daily functioning, and the patient may be unaware of its existence.
  2. Mild neurocognitive disorder: An acquired impairment in at least two cognitive domains as defined by a performance on neuropsychological testing of more than 1 SD below expected age and education-adjusted norms. This impairment does impact daily functioning to a mild degree. For example, work efficiency is decreased, but the patient can compensate for the deficits.
  3. HIV-associated dementia: An acquired impairment in at least two cognitive domains as defined by a performance on neuropsychological testing of more than 2 SD below expected age and education-adjusted norms. This impairment does impact daily functioning to a significant degree.
- Cognitive changes: Forgetfulness, poor attention and concentration, increased difficulty performing complex tasks, slowed psychomotor speed.
- Behavioral changes: Apathy, lack of initiative, social withdrawal, irritability, occasionally agitation, psychosis, or obsessive-compulsive disorder.
- Motor problems: Clumsiness, unsteady gait, poor balance, tremor, leg weakness.
- Progressive/later stages: Bedbound, severe dementia, bowel/bladder incontinence.
- Classically HIV-associated dementia was described as a classic subcortical dementia (attention, concentration, working memory, and executive function difficulties being prominent features). However, in the ART era, more patients are developing cortical features.
- Results from inflammation triggered by HIV itself (not related to opportunistic infection) and immune activation of microglia and brain macrophages.
- In children: Developmental delay, microcephaly, and spasticity are common.
- Table E1 summarizes features of HIV-associated neurocognitive disorder.

RISK FACTORS

- Low CD4 count (less than 200 cells/mm^3)
- High viral load
- Anemia
- Injection drug use
- Hepatitis C
- Female gender
- Older age

DIAGNOSIS

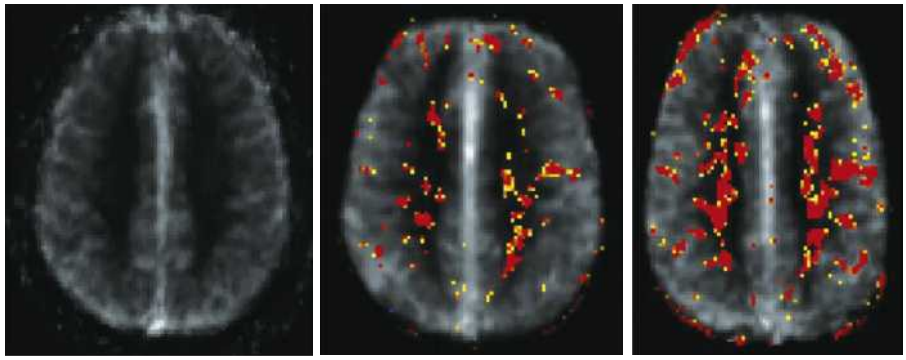
WORKUP

- Diagnosis is based on clinical examination and neuropsychologic tests and exclusion of opportunistic processes.
- CT of brain may show subcortical hypodensities, enlarged ventricles, and cortical atrophy greater than expected for age.
- MRI head (Fig. E1, Fig. E2): Diffuse, confluent, periventricular white matter hyperintensities on T2-weighted images with cortical atrophy and enlarged ventricles. The white matter hyperintensities are not mandatory for the diagnosis.
- Lumbar puncture: CSF analysis helps to rule out opportunistic infections. In HIV-related cognitive dysfunction, the CSF may show a nonspecific increase in cell count and protein but may also be normal.
- Subtle electrophysiologic abnormalities can be found in early HIV-1 infection (on

TABLE E1 Clinical Triad in Human Immunodeficiency Virus Type 1–Associated Neurocognitive Disorder

Cognition	Behavioral	Motor
Forgetfulness	Apathy	Gait instability
Mental slowing	Social withdrawal	Poor coordination
Decreased concentration	Lack of spontaneity	Leg weakness

From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases*, ed 8, Philadelphia, 2015, Saunders.



Asymptomatic MCMD HAD

FIG. E1 Perfusion MRI (pMRI) maps showing regions of increasing cerebral blood volume (CBV) with advancing HIV groups: Asymptomatic, minor cognitive–motor disorder (MCMD), and HIV-associated dementia (HAD). Areas of red indicate >2 standard deviations elevation in CBV. (Tucker KA et al: Neuroimaging in human immunodeficiency virus infection, *J Neuroimmunol* 157[1-2]:153-162, 2004.)

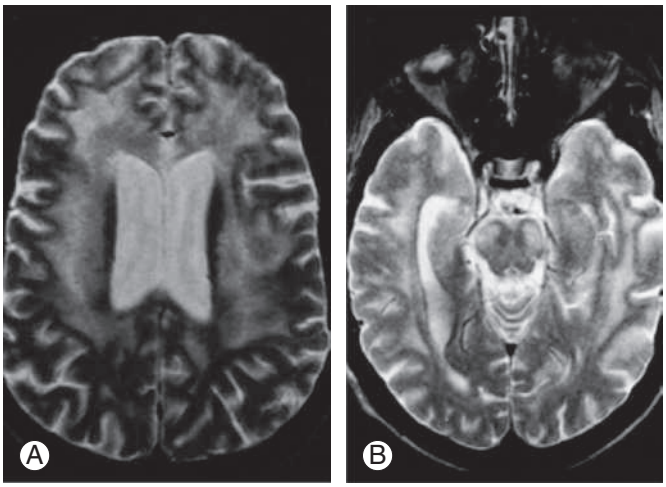


FIG. E2 Advanced HIV encephalopathy. Axial T2WI. There is diffuse confluent and symmetrical abnormal high signal returned from the white matter of the cerebral hemispheres **(A),** which is also extending into the brainstem to involve the cerebral peduncles **(B).** In this patient there is also generalized atrophy. Features that help to differentiate HIV from PML are the symmetry of the changes and the lack of signal abnormalities on T1WI. (From Adam A, Dixon AK, Grainger RG, Allison DJ. Grainger & Allison's diagnostic radiology, 5th ed. Churchill Livingstone, 2007, in Grant, LA: *Grainger & Allison's Diagnostic Radiology Essentials,* ed 2, 2019, Elsevier.)

electroencephalography, evoked potentials, nerve conduction studies), but they do not seem to have a predictive value for the later onset of HIV-associated dementia, which correlates most with a history of the CD4+ T-lymphocyte nadir of less than 200 cells/microliter.

- Potential causes for cognitive impairment that must be ruled out include:
  1. Opportunistic central nervous system (CNS) processes (e.g., toxoplasmosis, primary CNS lymphoma, progressive multifocal leukoencephalopathy, cytomegalovirus encephalitis, cryptococcal meningitis)
  2. HIV-mediated CD8 encephalitis
  3. General paresis of the insane due to syphilis
  4. Vitamin B_{12} deficiency resulting in subacute combined degeneration
  5. Substance use
  6. Alcoholism
  7. Psychiatric disorders such as depression, anxiety, bipolar disorder, or schizophrenia
  8. Side effects of prescribed medications

Rx TREATMENT

Early treatment with antiretroviral therapy (ART) may lead to clinical improvement in some patients, but in many cases, cognitive dysfunction persists despite ART.

Maintaining high CD4 count and not allowing CD4 count to nadir below 200 cells/microliter may protect against the development of HAND.

PEARLS & CONSIDERATIONS

- Initiation of ART can lead to rapid improvement in cognitive function in early stages
- Untreated, life span of patient with HIV-associated dementia is typically 4 to 6 mo.
- Most common presenting complaint in children infected with HIV.
- Patients may have other medical or psychiatric conditions or a social history that seriously confounds the diagnosis of HIV-associated neurocognitive disorder.
- Five HIV-related opportunistic infections that commonly cause cognitive impairment are toxoplasmosis, cryptococcal meningitis, progressive multifocal leukoencephalopathy, primary CNS lymphoma, and cytomegalovirus encephalitis.
- HIV-associated CD8 encephalitis is subacute, progressive encephalopathy characterized by diffuse perivascular and intraparenchymal CD8+ lymphocytic infiltration. MRI shows hyperintensity of the white matter on T2 sequences and linear or punctate enhancement in a perivascular distribution on T1 post-gadolinium sequences. CSF analysis reveals elevated protein and a CD8+ T-cell-predominant pleocytosis. Treatment is with high-dose corticosteroids and can result in a good outcome despite an initially poor neurological status.

REFERRALS

- Upon diagnosis/clinical suspicion for HIV-associated cognitive dysfunction, referral to neurology is recommended.
- Referral to neuropsychology may be considered.
- Referral to infectious disease specialist to manage HIV infection.

BASIC INFORMATION

DEFINITION

Compulsive hoarding is defined as the acquisition of and failure to discard a large number of possessions that appear to be useless or of limited value, with living spaces sufficiently cluttered so as to preclude activities for which those spaces were designed and significant distress or impairment in functioning caused by the hoarding. Hoarding has historically been a criterion of obsessive-compulsive personality disorder. With the publication of the DSM-5 (2013), compulsive hoarding is now recognized as a distinct form of psychopathology.

- Persistent difficulty discarding or parting with possessions, regardless of the value others may attribute to these possessions. (The Work Group is considering alternative wording: "Persistent difficulty discarding or parting with possessions, regardless of their actual value.")
- This difficulty is due to strong urges to save items and/or distress associated with discarding.
- The symptoms result in the accumulation of a large number of possessions that fill up and clutter active living areas of the home or workplace to the extent that their intended use is no longer possible. If all living areas become decluttered, it is only because of the interventions of third parties (e.g., family members, cleaners, authorities).
- The symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning (including maintaining a safe environment for self and others).
- The hoarding symptoms are not due to a general medical condition (e.g., brain injury, cerebrovascular disease).
- The hoarding symptoms are not restricted to the symptoms of another mental disorder (e.g., hoarding due to obsessions in obsessive-compulsive disorder, decreased energy in major depressive disorder, delusions in schizophrenia or another psychotic disorder, cognitive deficits in dementia, restricted interests in autism spectrum disorder, food storing in Prader-Willi syndrome).

Specify if:

- With excessive acquisition: If discarding possessions is accompanied by excessive acquisition of items that are not needed or for which there is no available space

Specify if:

- With good or fair insight
- With poor insight
- With absent insight/delusional beliefs

SYNONYMS

DSM-5 CODE
300.3 Obsessive compulsive disorder

EPIDEMIOLOGY, PREVALENCE & DEMOGRAPHIC

- Community surveys suggest that the prevalence of clinically significant compulsive hoarding is estimated to be somewhere between 2% and 6%. National studies on prevalence are not yet available.
- Clinical samples suggest a higher prevalence among females, but some epidemiologic studies suggest a higher prevalence among males.
- Hoarding onset typically starts in early adolescence.
- Late-onset hoarding is rare.
- Available data outside of the U.S. suggest that hoarding is a universal phenomenon.
- Hoarding tendencies tend to begin in childhood or adolescence and become clinically significant by middle age.
- Hoarding may have a sudden onset in adulthood after experiencing a traumatic event.
- A large percentage of individuals who hoard report having at least one first-degree relative who experiences hoarding problems. The link appears to be stronger among first-degree female relatives (e.g., mothers, sisters).
- It is estimated that one in four people with OCD are hoarders.
- Hoarding tends to be a chronic condition with spontaneous remission a rarity.

Associated with Axis I (Major Depressive Disorder, Social Phobia, Obsessive-Compulsive Disorder, Generalized Anxiety Disorder, and Attention-Deficit Hyperactivity Disorder) and Axis II (Borderline Personality Disorder and Avoidant Personality Disorder).

RISK FACTORS

- Genetic vulnerabilities and early attachment experiences are thought to contribute to hoarding behavior.
- Social isolation can lead to hoarding behavior as a way to provide comfort.
- A sudden traumatic event can lead to hoarding behavior as a coping mechanism.
- Family history.
- Age.

ETIOLOGY

Although the etiology is unknown, hoarders share a number of characteristics, including problems with emotional attachments to possessions (i.e., viewing their possessions as extensions of themselves), behavioral avoidance (i.e., a fear of making a decision about what to do with a possession), beliefs about the nature of possessions (i.e., an exaggerated desire for control over possessions and a sense of responsibility to take care of the possessions and to be prepared for the future), perfectionism (i.e., possessions must be used perfectly such as a belief that a newspaper must be thoroughly read), information-processing deficits (i.e., deficits in decision making, difficulty in memory functions, and deficits in categorization and organization), and an avoidance of waste. Physical abuse and sexual trauma have been associated with greater acquiring tendencies but not with saving. Intense negative emotional reactions (sadness) may also play a role in the etiology. Hoarding in children has been associated with behavioral and emotional dysregulation.

DIAGNOSIS

WORKUP

Hoarding disorder is not diagnosed if the hoarding behavior is determined to be the direct consequence of another medical condition, including traumatic brain injuries, surgery for seizure control, cerebrovascular disease, infections of the central nervous system, neurogenetic conditions, autism, schizophrenia, major depressive episode, obsessive-compulsive disorder, or neurocognitive disorders.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Frost and Hartl developed a cognitive-behavioral model of hoarding, which conceptualizes hoarding as a consequence of (1) information-processing deficits, (2) problems in forming emotional attachments, (3) behavioral avoidance, and (4) erroneous beliefs about the nature of possessions.
- Steketee and Frost published a specialized cognitive-behavioral therapy (CBT) compulsive hoarding treatment manual that uses cognitive-behavioral strategies to address these areas. The authors recommend 26 therapy sessions over a period of 1 yr. Treatment can be individual or group therapy with a combination of office and in-home sessions. Family consultation is recommended, with an emphasis on education and the treatment of hoarding behavior.
- Specific variables, including female gender, younger age, a greater number of CBT sessions, and a greater number of home visits, have been associated with a better clinical outcome.

ACUTE GENERAL Rx

Antidepressants may be helpful for underlying mood or anxiety disorders.

CHRONIC Rx

- CBT is the preferred treatment for hoarding disorder, but selective serotonin reuptake inhibitors (SSRIs) are the preferred pharmacologic intervention for severe cases.
- A recent review of CBT, pharmacologic, and family-based interventions yielded modest statistically significant improvements.
- A systematic review of treatment with cognitive-behavioral therapy for hoarding that compared therapy traditionally used to treat

obsessive-compulsive disorder with therapy specifically designed for hoarding disorder suggested improvement in hoarding symptoms with both interventions. However, when compared to each other, the efficacy of these treatments is inconclusive.
- New research suggests the potential benefit of Internet-based CBT for hoarding disorder.

DISPOSITION

Long-term follow-up is essential for recurring hoarding behavior and to address underlying mood disorders.

REFERRAL

- CBT is the preferred treatment.
- If underlying mood symptoms such as depression and anxiety interfere with treatment, a referral for medication is encouraged.

PEARLS & CONSIDERATIONS

Patients with hoarding disorder can be challenging to treat because many with the disorder do not recognize that they have a problem nor do they understand the negative impact hoarding has on their lives and the lives of their loved ones. They often do not believe that they need treatment, and they take great comfort in their possessions. Patient and family education is an important first step in the treatment of hoarding disorder. Family members are often frustrated and angry at the individual who hoards because of a perception that the hoarder is simply "messy," "lazy," etc. Psychoeducation helps family members understand the complicated nature of the illness. They can be instructed on how to become "surrogate therapists" rather than distress the family member who hoards by taking it upon themselves to throw items away. It is essential that they work with a therapist who has expertise with hoarding behavior.

BASIC INFORMATION

DEFINITION

Hodgkin lymphoma is a malignant disorder arising from germinal center B cells and characterized histologically by the presence of multinucleated giant cells (Reed-Sternberg cells) in a mixed inflammatory background.

ICD-10CM CODES

C81.90	Hodgkin lymphoma, unspecified, unspecified site
C81.00	Nodular lymphocyte predominant Hodgkin lymphoma, unspecified site
C81.10	Nodular sclerosis classical Hodgkin lymphoma, unspecified site
C81.20	Mixed cellularity classical Hodgkin lymphoma, unspecified site
C81.30	Lymphocyte depleted classical Hodgkin lymphoma, unspecified site
C81.79	Other classical Hodgkin lymphoma, extranodal and solid organ sites
C81.90	Hodgkin lymphoma, unspecified, unspecified site
C81.91	Hodgkin lymphoma, unspecified, lymph nodes of head, face, and neck
C81.92	Hodgkin lymphoma, unspecified, intrathoracic lymph nodes
C81.93	Hodgkin lymphoma, unspecified, intra-abdominal lymph nodes
C81.94	Hodgkin lymphoma, unspecified, lymph nodes of axilla and upper limb
C81.95	Hodgkin lymphoma, unspecified, lymph nodes of inguinal region and lower limb
C81.96	Hodgkin lymphoma, unspecified, intrapelvic lymph nodes
C81.97	Hodgkin lymphoma, unspecified, spleen
C81.98	Hodgkin lymphoma, unspecified, lymph nodes of multiple sites
C81.99	Hodgkin lymphoma, unspecified, extranodal and solid organ sites

EPIDEMIOLOGY & DEMOGRAPHICS

- There is a bimodal age distribution (15 to 34 yr and >50 yr).
- Incidence is 4 in 100,000 cases; >8000 new cases of Hodgkin lymphoma diagnosed annually in the U.S.
- Concordance for Hodgkin lymphoma in identical twins suggests that a genetic susceptibility underlies Hodgkin lymphoma in young adulthood.
- There is association between certain HLA haplotypes, especially HLA-A1.
- The disease is more common in males (in childhood Hodgkin lymphoma, >80% occur in males), whites, and higher socioeconomic groups.
- There is an increased risk in smokers and HIV-infected individuals.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Painless palpable lymphadenopathy is the most common presenting symptom
- The most common site of involvement is the neck region
- Fever and night sweats: Fever in a cyclical pattern (days or wks of fever alternating with afebrile periods) is known as Pel-Ebstein fever
- Unexplained weight loss, generalized malaise
- Persistent, nonproductive cough
- Lymph node pain associated with alcohol ingestion often because of heavy eosinophil infiltration of the tumor sites is relatively uncommon
- Generalized pruritus
- Hepatosplenomegaly
- Other: Superior vena cava syndrome, spinal cord compression (rare), erythema nodosum (very rare), ichthyosis (very rare)

ETIOLOGY

- Evidence implicating Epstein-Barr virus remains controversial.
- Cigarette smoking has also been implicated.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Non-Hodgkin lymphoma
- Sarcoidosis
- Infections (e.g., cytomegalovirus, Epstein-Barr virus, toxoplasmosis, HIV, tuberculosis)
- Drug reaction

WORKUP

Diagnosis is confirmed by lymph node biopsy. The World Health Organization classifies Hodgkin lymphoma into two groups: Classical Hodgkin lymphoma (92% to 97%) and nodular lymphocyte-predominant Hodgkin lymphoma (3% to 8%). Classical Hodgkin lymphoma has four main histologic subtypes based on the number of lymphocytes, Reed-Sternberg cells, and the presence of fibrous tissue (Table 1):

- Nodular sclerosis (Fig. E1)
- Mixed cellularity (Fig. E2)
- Lymphocyte rich
- Lymphocyte depleted

Nodular sclerosis occurs mainly in young adulthood, whereas the mixed cellularity type is more prevalent after age 50 yr. Table 2 summarizes key features of Hodgkin lymphomas.

Staging: Table 3 describes the Cotswolds Staging Classification.

Proper staging requires the following:

- Detailed history (with documentation of "B symptoms" and physical examination)
- Excisional biopsy with histologic, immunophenotypic and immunohistochemical analysis
- Laboratory evaluation (complete blood count, erythrocyte sedimentation rate [ESR], blood urea nitrogen, creatinine, liver function tests, albumin, lactate dehydrogenase, HIV test), immunophenotypic markers (see Table 4)
- Positron emission tomography (PET)/computed tomography (CT) scan of the chest, abdomen, and pelvis
- Unilateral bone marrow biopsy in selected patients

Box 1 summarizes recommended staging procedures for Hodgkin lymphoma.

TREATMENT

ACUTE GENERAL Rx

The main therapeutic modality includes chemotherapy with or without radiotherapy depending on stage and other risk factors (Table 5). In general, chemotherapy plus involved-site radiotherapy is standard treatment for Hodgkin lymphoma in the early stages; however, recent data suggest that chemotherapy alone is appropriate for a significant proportion of patients. Chemotherapy (Table 6) is used for advanced stage disease with radiotherapy in selected patients, such as those with bulky disease.

Most oncologists prefer the combination of adriamycin (doxorubicin), bleomycin, vinblastine, and dacarbazine (ABVD). ABVD does not cause infertility or stem cell damage and has also shown to be effective in patients with HIV infection and Hodgkin lymphoma. Table 7 describes characteristics of the ABVD regimen.

Recent trials have shown that in patients with early-stage Hodgkin lymphoma and favorable prognosis, defined by fewer than three nodal sites without bulky or extranodal disease in the absence of ESR >50 without symptoms or 30 with symptoms, treatment with two cycles of ABVD followed by 20 Gy of involved-field radiation therapy may be as effective as, and less toxic than, four cycles of ABVD followed by 30 Gy of involved-field radiation therapy. For patients with early stage disease who do not meet these criteria, options include three or four cycles of ABVD plus involved site radiotherapy

TABLE 1 Frequency of Histologic Subtypes of Hodgkin Lymphoma According to the 2008 WHO Classification

Classic Hodgkin Lymphoma (cHL)	95%
• Nodular sclerosis classic Hodgkin lymphoma (NSCHL)	70%
• Mixed cellularity classic Hodgkin lymphoma (MCCHL)	20%-25%
• Lymphocyte-rich classic Hodgkin lymphoma (LRCHL)	5%
• Lymphocyte-depleted classic Hodgkin lymphoma (LDCHL)	<1%
Nodular Lymphocyte Predominant Hodgkin Lymphoma (NLPHL)	5%

From Hoffman R et al: *Hematology, basic principles and practice*, ed 7, Philadelphia, 2018, Elsevier.

TABLE 2 Key Features of Hodgkin Lymphoma

Lymphoma	Demographics, Clinical Presentation	Morphology	Cell Surface Markers	Prognosis
Nodular, lymphocyte predominant (NLPHL)	M > F, 30-50 yr, with peripheral lymphadenopathy	Mononuclear cells with convoluted nuclei (popcorn or L&H cells) loosely aggregated in nodules of small B cells	CD45, CD20, bcl-6, J-chain, Oct-2, BOB.1, EBV absent in LP cells	Excellent for stages I, II
Nodular sclerosis	M = F, <30 yr with mediastinal mass, occasional spleen or lung involvement; 40% have B symptoms; most patients present with stage II disease	Broad bands of collagen, nodules of lymphoid tissue with aggregates of HRS cells and lacunar cells, multinucleated variants	CD15, CD30, CD45-EBV in 1%-40%	Good with systemic therapy
Mixed cellularity	M > F; median age, 38 yr; peripheral lymphadenopathy common, spleen, BM; B symptoms common; patients often stage III or IV	Classic HRS cells in mixture of lymphocytes, plasma cells, eosinophils, histiocytes	CD15, CD30, CD45-EBV in 75%	Good with systemic therapy
Lymphocyte depletion	M > F; median age, 30-37 yr; B symptoms, advanced stage common; associated with HIV	Classic HRS cells common with paucity of background lymphocytes; pleomorphic HRS cells mimic sarcoma	CD15, CD30, CD45-EBV positive in HIV-affected patients	Associated with advanced stage
Lymphocyte-rich classical	M > F, older age; peripheral lymphadenopathy; B symptoms rare; most patients with stage I or II disease	Scattered classic HRS cells among numerous small lymphocytes; nodular growth pattern	CD15, CD30; Oct2 and BOB.1 vary; J-chain absent; EBV in 40%-75%	Good, similar to NLPHL

BM, Bone marrow; *EBV,* Epstein-Barr virus; *F,* female; *HIV,* human immunodeficiency virus; *HRS,* Hodgkin Reed-Sternberg; *L&H,* lymphocytic and histiocytic; *LP,* lymphoplasmacytic; *M,* male.
From McPherson RA, Pincus MR: *Henry's clinical diagnosis and management by laboratory methods*, ed 23, St Louis, 2017, Elsevier.

TABLE 3 Cotswolds-Modified Ann Arbor Staging System for Hodgkin Lymphoma

Stage	Criteria
I	Disease affecting a single lymph node region or lymphoid structure (e.g., spleen, thymus, Waldeyer ring)
II	Disease affecting two or more discrete lymph node regions confined to the same side of the diaphragm
III	Disease affecting two or more discrete lymph node regions or lymphoid structures on both sides of the diaphragm
IV	Disease that has spread to one or more extranodal sites (that do not meet the criteria for E) or extralymphatic structure including involvement of the bone marrow, liver, or lungs
Designation	**Criteria**
A	Absence of B symptoms[a]
B	Presence of B symptoms[a]
S	Involvement of the spleen
E	Single extranodal site or involvement of an extranodal site that is contiguous to an involved nodal region
X	Bulky disease as defined as >1/3 mediastinum at its widest part or a nodal mass >10 cm at its greatest diameter

[a]B symptoms: Constitutional symptoms including night sweats, fevers, or weight loss (>10% over 6 mo).
From Hoffman R et al: *Hematology, basic principles and practice*, ed 7, Philadelphia, 2018, Elsevier.

TABLE 4 Selected Immunophenotypic Markers and Histologic Characteristics of Use in the Differential Diagnosis of Hodgkin Lymphoma and Other Lymphoid Neoplasms

Marker	Classical HL	Nodular Lymphocyte Predominant HL	TCRBCL	ALCL
CD30	+	–	–	+
CD15	+	–	–	–
CD20	–/+*	+	+	–
CD45	–	+	+	+/–
CD79a	–	+	+	–
ALK	–	–	–	+/–
EMA	–	+	+	+
Nodular growth protein	+/–†	+	–	–

*CD20 positivity in classical Hodgkin lymphoma is quite heterogeneous, with a wide range in brightness of staining.
†In classical Hodgkin lymphoma, a nodular growth pattern is confined to the nodular sclerosing subtype.
+, >90% of cases positive; +/–, majority of cases positive; –/+, minority of cases positive; –, <10% of cases positive; *ALCL,* anaplastic large cell lymphoma; *HL,* Hodgkin lymphoma; *TCRBCL,* T-cell rich B-cell lymphoma.
From Abeloff MD: *Clinical oncology*, ed 3, Philadelphia, 2004, WB Saunders.

to 30 Gy. In addition, chemotherapy alone, in the absence of bulky disease, is an alternative approach, especially in women younger than 30 yr given the increased risk of including breast cancer, as well as cardiac and thyroid disease. Although the risk of disease recurrence is slightly higher in patients who receive chemotherapy alone, there is no difference in overall survival.

BEACOPP, an intensified regimen consisting of bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone, has been advocated by some as the new standard for treatment of advanced Hodgkin lymphoma in place of ABVD. Recent trials have shown that treatment with BEACOPP, as compared with ABVD, results in better initial tumor control, but the long-term clinical outcome does not differ significantly between the two regimens. In addition, with the use of the escalated BEACOPP regimen, the rate of complications is higher (3% treatment-related death, 20% rate of hospitalization, and 3% rate of secondary leukemia, and near-universal infertility). Thus, if the goal is cure with the least overall toxic effects, it is best to favor ABVD therapy, reserving rescue therapy with high-dose chemotherapy and autologous hematopoietic stem-cell transplantation for the small number of patients in whom the primary treatment fails.

In March 2018, the FDA approved the combination of brentuximab vedotin and doxorubicin, vinblastine and dacarbazine (AVD) for previously untreated, stage III or IV Hodgkin lymphoma patients. The combination of brentuximab vedotin and AVD was associated with a longer median modified progression-free survival than ABVD, but also was associated with higher rates of neutropenia and neuropathy.

- Definitions of treatment groups are described in Table 8.
- Recommendations for the primary treatment of Hodgkin lymphoma outside of clinical trials are described in Table 9.

BOX 1 Recommended Staging Procedures for Hodgkin Lymphoma

The following staging procedures are recommended for the initial workup of Hodgkin lymphoma:

1. Adequate surgical biopsy reviewed by an experienced hematopathologist
2. Cytologic examination of any effusion in selected cases
3. Detailed history, with attention to the presence or absence of systemic symptoms, and a careful physical examination, emphasizing node chains, size of the liver and spleen, and inspection of Waldeyer ring
4. Routine laboratory tests: Complete blood cell count, erythrocyte sedimentation rate, and liver function tests
5. Neck, chest, and abdominal CT imaging fused with 18-FDG PET scan (Fig. E3)

From Hoffman R et al: *Hematology: basic principles and practice,* ed 5, Philadelphia, 2009, Churchill Livingstone.

TABLE 5 Standard Treatment Approach According to Prognostic Group

Early-favorable HL	Combined modality therapy • 2-4 cycles of chemotherapy followed by involved-field radiotherapy
Early-unfavorable HL (intermediate-stage)	Combined modality therapy • 4-6 cycles of chemotherapy followed by involved-field radiotherapy
Advanced HL	Extensive chemotherapy • 6-8 cycles of chemotherapy ± consolidation with localized radiotherapy

CT, Computerized tomography; *HL*, Hodgkin lymphoma.
From Hoffman R et al: *Hematology, basic principles and practice*, ed 7, Philadelphia, 2018, Elsevier.

TABLE 6 Standard Chemotherapy Regimens for the Treatment of Advanced Hodgkin Lymphoma

Regimen	Drugs	Route	Schedule
ABVD	Adriamycin 25 mg/m^2	IV	Day 1 and 15
	Bleomycin 10 mg/m^2	IV	Day 1 and 15
	Vinblastine 6 mg/m^2	IV	Day 1 and 15
	Dacarbazine 375 mg/m^2	IV	Day 1 and 15
			Every 28 days
BEACOPP (escalated)	Bleomycin 10 mg/m^2	IV	Day 8
	Etoposide 200 mg/m^2	IV	Day 1-3
	Adriamycin 35 mg/m^2	IV	Day 1
	Cyclophosphamide 1250 mg/m^2	IV	Day 1
	Vincristine 1.4 mg/m^2	IV	Day 8
	Procarbazine 100 mg/m^2	PO	Days 1-7
	Prednisolone 40 mg/m^2	PO	Days 1-14
	G-CSF	SC	From day 8
			Every 21 days

ABVD, Adriamycin, bleomycin, vinblastine, and dacarbazine; *BEACOPP,* bleomycin, etoposide, Adriamycin (doxorubicin), cyclophosphamide, Oncovin (vincristine), procarbazine, and prednisone; *G-CSF*, granulocyte colony-stimulating factor; *IV,* intravenous; *PO,* by mouth; *SC,* subcutaneous.

TABLE 7 Characteristics of the ABVD Regimen

Agents: Doxorubicin, bleomycin, vinblastine, dacarbazine
All intravenous, total compliance
80% complete response rate
10% primary refractory disease
60%-65% overall disease-free survival
Most relapses occur within the first 4 yr; however, about 10% of all relapses occur beyond 5 yr
Major side effects are nausea, phlebitis, myelosuppression, less cumulative myelotoxicity than MOPP
No infertility
No leukemia

ABVD, Adriamycin (doxorubicin), bleomycin, vinblastine, dacarbazine; *MOPP,* mechlorethamine, Oncovin (vincristine), procarbazine, prednisone.
From Abeloff MD: *Clinical oncology*, ed 3, Philadelphia, 2004, WB Saunders.

- In 2011, the FDA approved the use of the anti-CD30 antibody drug conjugate brentuximab vedotin for the treatment of patients with Hodgkin lymphoma who have relapsed after autologous stem cell transplant and for patients who have relapsed but are not candidates for transplant. Brentuximab vedotin is associated with an overall response rate of 75%.
- In August 2015, brentuximab vedotin was approved as consolidation therapy after autologous transplant in patients at high risk for relapse. The median progression-free survival with brentuximab vedotin was 43 mo vs. 24 mo in patients who received placebo.
- In May 2016, the FDA approved the anti-PD-1 monoclonal antibody nivolumab for patients with Hodgkin lymphoma who relapsed after autologous stem cell transplant and post-transplant brentuximab vedotin. The overall response rate to nivolumab was 65%, and the complete response rate was 7%.
- In March 2017, the FDA approved the anti-PD-1 monoclonal antibody pembrolizumab in patients with refractory disease or those who have relapsed after three or more lines of therapy. The overall response rate was 69%, and the complete response rate was 22%.

DISPOSITION

- Cure rates as high as 85% to 90% in early stage patients and 75% in stage III/V disease are now possible with appropriate initial therapy.
- Poor prognostic features (Table 10, Table 11) include presence of B symptoms, advanced age, advanced stage at initial presentation, male sex, low albumin, high ESR, lymphocyte depletion histology, and increased number of tumor-associated macrophages.
- Unlike escalated BEACOPP, ABVD is not associated with a risk of leukemia.
- Mediastinal irradiation increases the risk of subsequent cardiac disease, including valvular and pericardial disease, accelerated coronary artery disease, and conduction abnormalities.
- Radiation therapy increases the risk of developing secondary solid tumors, especially breast cancer in women younger than age 30 yr (Table 12).
- Table 13 describes potential late complications of Hodgkin lymphoma treatment and appropriate clinical responses and preventive strategies.

REFERRAL

- To surgery for lymph node biopsy
- Fertility clinic for sperm banking
- Hematology/oncology
- Radiation oncology, in selected cases

PEARLS & CONSIDERATIONS

COMMENTS

- Young male patients should consider sperm banking before the initiation of therapy even

TABLE 8 Definition of Treatment Groups According to the EORTC/GELA and GHSG

Treatment Group	EORTC/GELA	GHSG	NCIC/ECOG
Early-stage favorable	CS I-II without risk factors (supradiaphragmatic)	CS I-II without risk factors	Standard risk group: Favorable CSD I-II (without risk factors)
Early-stage unfavorable (intermediate)	CS I-II with ≥1 risk factors (supradiaphragmatic)	CS I, CSIIA ≥1 risk factors; CS IIB with C/D but without A/B	Standard risk group: Unfavorable CS I-II (at least one risk factor)
Advanced stage	CS III-IV	CS IIB with A/B; CS III-IV	High-risk group: CS I or II with bulky disease; intraabdominal disease; CS III, IV
Risk factors (RF)	A large mediastinal mass B age ≥50 yr C elevated ESR* D ≥4 involved regions	A large mediastinal mass B extranodal disease C elevated ESR* D ≥3 involved areas	A ≥40 yr B not NLPHL or NS histology C ESR ≥50 mm/h D ≥4 involved nodal regions

BEACOPP, Bleomycin, etoposide, Adriamycin (doxorubicin), cyclophosphamide, Oncovin (vincristine), procarbazine, and prednisone.
From Abeloff MD: *Clinical oncology*, ed 3, Philadelphia, 2004, Saunders.

though the risk of infertility with ABVD is low. Symptomatic males, particularly with advanced stage Hodgkin lymphoma, may have disease-related oligospermia at diagnosis.

- Chemotherapy with or without involved-field radiotherapy should be the standard treatment for Hodgkin lymphoma with early stage disease. Chemotherapy with radiation in selected cases should be the standard of care for advanced stage.
- After failure of ABVD therapy, more than 60% of patients who have had a relapse and about 30% of patients with initially refractory lymphoma can be reliably cured with high-dose chemotherapy and autologous hematopoietic stem-cell transplantation.

Hodgkin Lymphoma (Patient Information)

AUTHORS: **Jorge J. Castillo, MD,** and **Ann S. LaCasce, MD, MMSc**

TABLE 13 Potential Late Complications of Hodgkin Lymphoma Treatment and Appropriate Clinical Responses and Preventive Strategies

Risk/Problem	Incidence/Response
Dental caries	Neck or oropharyngeal irradiation can cause decreased salivation. Patients should have careful dental care follow-up and should make their dentist aware of the previous irradiation.
Hypothyroidism	After external beam irradiation that encompasses the thyroid with doses sufficient to cure Hodgkin lymphoma, at least 50% of patients will eventually become hypothyroid. All patients whose TSH level becomes elevated should be treated with lifelong thyroxine replacement in doses sufficient to suppress TSH levels to low normal. This is also necessary to ensure that the radiation-damaged thyroid is not subjected to long-term stimulation by thyroid-stimulating hormone, which can increase the risk of thyroid neoplasm.
Infertility	ABVD is not known to cause any permanent gonadal toxicity, although oligospermia for 1-2 yr after treatment is common. Direct or scatter radiation to gonadal tissue can cause infertility, amenorrhea, or premature menopause, but this seldom occurs with the current fields used for the treatment of Hodgkin lymphoma. Thus, with the current chemotherapy regimens and radiation fields used, most patients will not develop these problems. In general, after treatment, women who continue menstruating are fertile, but men require semen analysis to provide a specific answer. High-dose chemoradiotherapy and hematopoietic stem cell transplantation almost always cause permanent infertility in both genders, although some young women occasionally recover fertility.
Impaired immunity to infections	Hodgkin lymphoma and its treatment can lead to lifelong impairment of full immunity to infection. All patients should be given annual influenza immunization and pneumococcal immunization every 5 yr. Patients whose spleen has been irradiated or removed should also be immunized against meningococcal types A and C and *Haemophilus influenza* type B. As for all adults, diphtheria and tetanus immunizations should be kept up-to-date.
Secondary neoplasms	Although uncommon, certain secondary neoplasms occur with increased frequency in patients who have been treated for Hodgkin lymphoma. These include acute myelogenous leukemia, thyroid, breast, lung, and upper gastrointestinal carcinoma and melanoma, and cervical carcinoma in situ. It is appropriate to screen for these neoplasms for the rest of the patient's life because they might have lengthy induction periods.

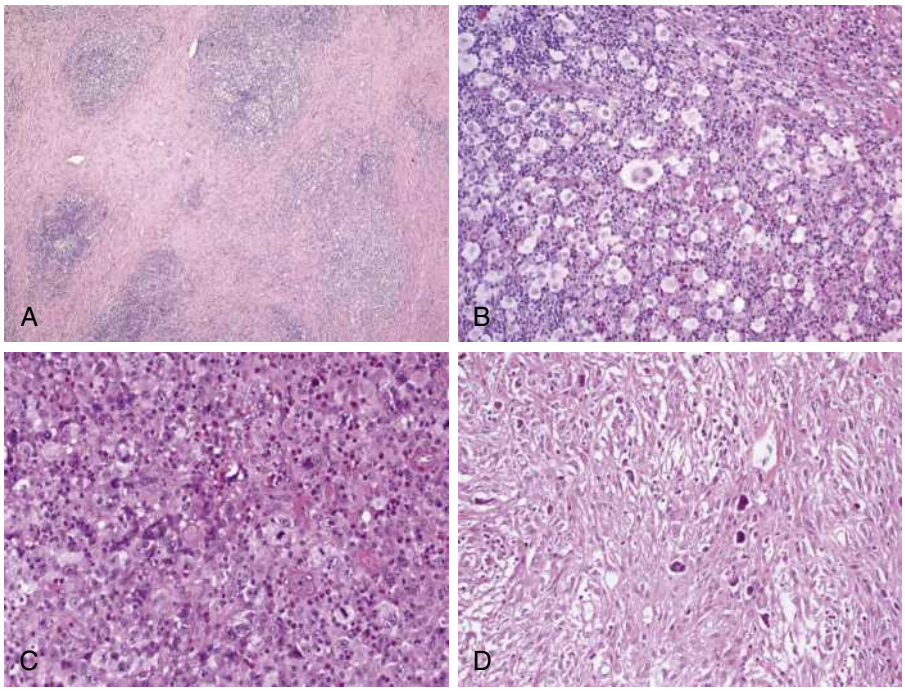

FIG. E1 Hodgkin lymphoma. Morphology of classical Hodgkin lymphoma (CHL). **A,** Nodular sclerosis CHL. Cellular nodules are separated by concentric bands of mature collagen. **B,** Close-up of cellular nodule shows numerous lacunar cells with clear cytoplasm intermingled with lymphocytes, neutrophils, and eosinophils. Note collagen bands rimming the nodule. **C,** Nodular sclerosis CHL grade II. Confluent sheets of neoplastic cells with partly anaplastic features intermingled with a minority of inflammatory cells. This morphology is consistent with the so-called syncytial variant of CHL. **D,** Lymphocyte-depleted CHL, diffuse fibrosis subtype. Neoplastic Reed-Sternberg and Hodgkin cells in a hypocellular background with histiocytes and fibroblasts. This case lacks nodularity and ordered collagen bands. (From Jaffe ES et al: *Hematopathology,* Philadelphia, 2011, WB Saunders.)

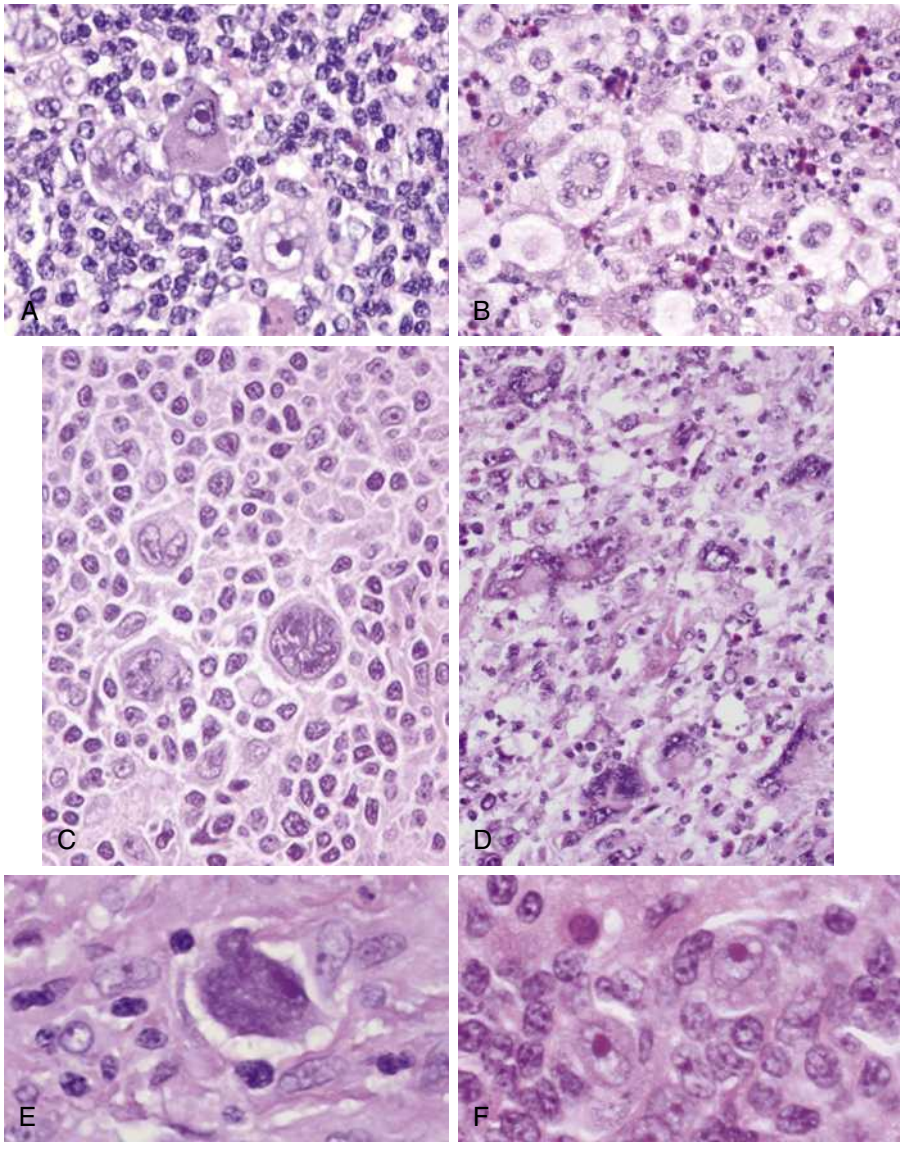

FIG. E2 Hodgkin lymphoma. Cytologic features of Reed-Sternberg (RS) cells and Hodgkin cells. **A,** Classic RS cells and variants in mixed cellularity—classical Hodgkin lymphoma (CHL), with amphophilic cytoplasm, large nuclei with clear karyoplasm, and huge viral inclusion-like nucleoli. **B,** Typical lacunar cells in a case of nodular sclerosis CHL. Note the delicate folded nuclear membranes, less conspicuous nucleoli, and ample clear cytoplasm with threadlike protrusions. **C,** Typical RS cells, including a binuclear variant, in mixed cellularity CHL. **D,** Abundant, sometimes bizarre multinucleated tumor cells in a case of nodular sclerosis grade II. **E,** So-called mummified RS cell with condensed, deeply basophilic cytoplasm. **F,** Two classic mononuclear Hodgkin cells in a case of mixed cellularity CHL. (From Jaffe ES et al: *Hematopathology,* Philadelphia, 2011, WB Saunders.)

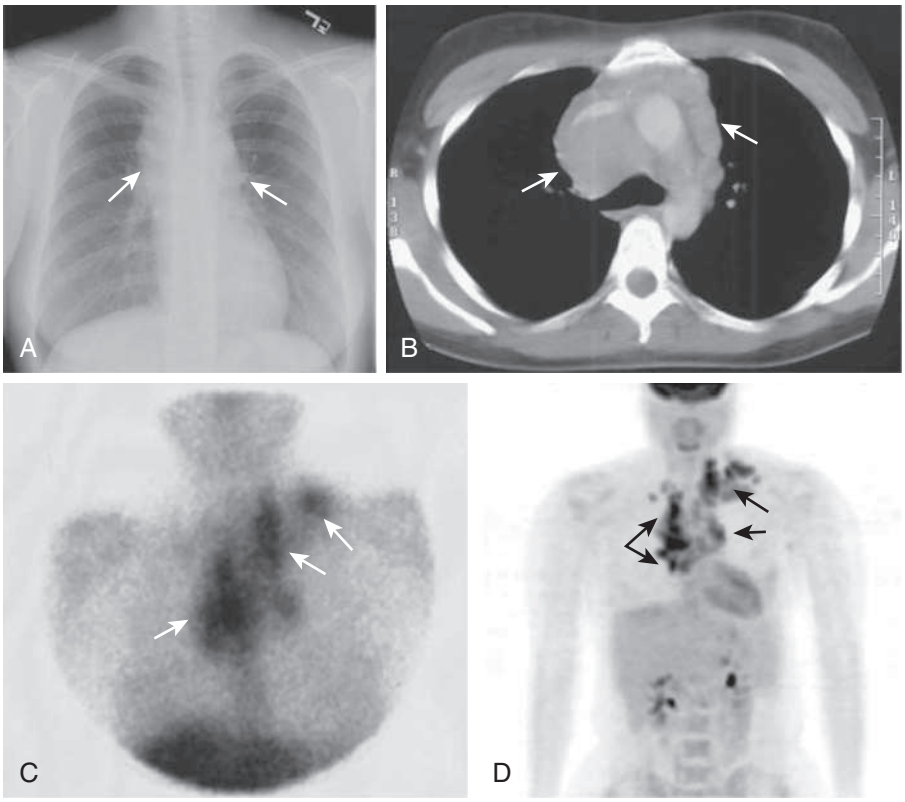

FIG. E3 Imaging of Hodgkin lymphoma. Bulky Hodgkin disease as seen on chest radiograph **(A)**, computed tomography (CT) of the chest **(B)**, gallium scan **(C)**, and positron emission tomography (PET) **(D)**. The *arrows* indicate sites of disease. Note that the PET and CT scans provide more detailed information than the chest radiograph and gallium scan. (From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.)

BASIC INFORMATION

DEFINITION

Hookworm is a parasitic infection of the intestine caused by the soil helminths *Necator americanus* (North and South America, Central Africa and parts of Asia) and *Ancylostoma duodenale* (Mediterranean nations, India, Iran, Far East). The hookworm of dogs and cats, *Ancylostoma ceylanicum*, (India, Southeast Asia) also can affect humans.

SYNONYMS

Ground itch
Ancylostoma duodenale infection
Necator americanus infection

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Varies greatly in different areas of the U.S.
- Most common in rural areas of southeastern U.S.
- Poor sanitation and increased rainfall increase incidence.

PREVALENCE (IN U.S.): Varies from 10% to 90% in regions where it is found.
PREDOMINANT AGE: Schoolchildren

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Nonspecific abdominal complaints
- Symptoms related to iron deficiency anemia depending on the amount of iron in the diet and worm burden (these organisms consume host's RBCs)
- Fatigue, tachycardia, dyspnea, and high-output failure
- Hypoproteinemia and edema from loss of proteins into the intestinal tract
- Unusual for pulmonary manifestations to occur when the larvae migrate through the lungs
- Skin rash at sites of larval penetration in some individuals without prior exposure: Ground itch

ETIOLOGY

Two main species can cause this disease: *N. americanus* and *A. duodenale. N. americanus* is the predominant cause of hookworm in the U.S. They are soil nematodes (geohelminthic infections) that are acquired by skin contact (i.e., bare feet) with contaminated soils in moist, warm climate. Worldwide, over 700 million people are infected.

- Infection occurs via penetration of the skin by the larval form, with subsequent migration via the bloodstream to the alveoli, up the respiratory tract, then into the GI tract (Fig. 1).
- *Ancylostoma* spp. infection can also occur via the oral route through ingestion of contaminated water supplies.
- Sharp mouth parts allow for attachment to intestinal mucosa.
- *Ancylostoma* spp. are more likely to cause iron deficiency anemia because they are larger and remove more blood daily from the bowel wall than the other hookworm species, *N. americanus.*

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Strongyloidiasis
- Ascariasis
- Other causes of iron deficiency anemia and malabsorption

WORKUP

Examine stool for hookworm eggs. Shedding of eggs starts around 8 wk after skin penetration in *N. americanus* infections and longer with *A. duodenale,* but eggs are indistinguishable between the two species. PCR stool assays are available in reference labs.

LABORATORY TESTS

CBC to show hypochromic, microcytic anemia; possible mild eosinophilia and hypoalbuminemia

IMAGING STUDIES

Chest x-ray: Generally not helpful, occasionally shows opacities

TREATMENT

NONPHARMACOLOGIC THERAPY

- Prevention of disease by not walking barefoot and by improving sanitary conditions.
- Vaccines are in development.

ACUTE GENERAL Rx

- Albendazole 400 mg PO as a single dose or daily for 3 days is the preferred treatment.
- Mebendazole 100 mg PO bid for 3 days is more effective than as a 500-mg single dose.
- Pyrantel pamoate 11 mg/kg (to max dose of 1 g) PO qd × 3 days.
- Iron supplementation may be helpful in patients with iron deficiency.

DISPOSITION

Easily treated

REFERRAL

To gastroenterologist and infectious disease specialist if diagnosis uncertain

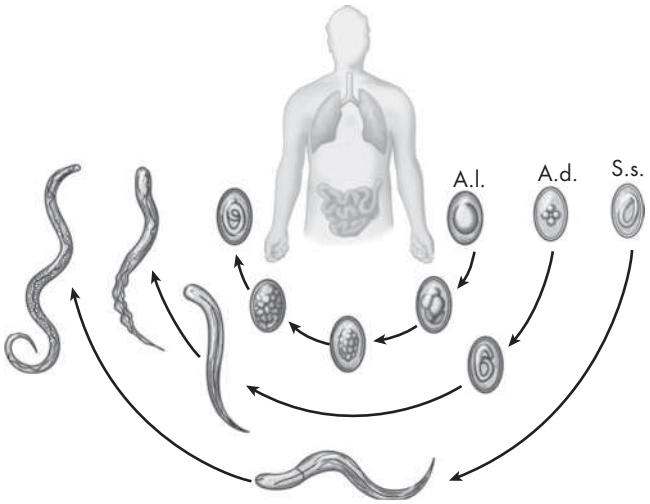

FIG. 1 Life cycle of intestinal nematodes with a migratory phase through the lungs. Eggs are passed with stools in *Ascaris lumbricoides (A.l.), Necator americanus,* or *Ancylostoma duodenale (A.d.),* or they hatch on their way out in *Strongyloides stercoralis (S.s.).* Ascaris eggs mature in soil, and humans are infected upon ingestion of these eggs. With hookworm and strongyloidiasis, humans are infected via skin penetration by filariform larvae. In all three infections, larvae pass through a migratory phase via the lungs before reaching maturity at their final habitat in the small intestine. (From Mandell GL et al: *Principles and practice of infectious diseases,* ed 7, Philadelphia, 2010, Churchill Livingstone.)

PEARLS & CONSIDERATIONS

COMMENTS

- Appropriate disposal of human waste is important in controlling the disease in areas with a high prevalence of hookworm infestation.
- Wearing shoes will avoid contact with contaminated soil, and the provision of safe water and sanitation for disposing human excreta is important in control of hookworm.

Horner Syndrome (PTG)

BASIC INFORMATION

DEFINITION

Horner syndrome is the clinical triad of ipsilateral ptosis, miosis, and sometimes facial anhidrosis. Disruption of any of the three neurons in the oculosympathetic pathway (first-order, second-order, or third-order) can cause Horner syndrome.

SYNONYMS

Oculosympathetic paresis

Raeder paratrigeminal syndrome: Horner syndrome of the third-order neuron associated with pain in the trigeminal nerve distribution

ICD-10CM CODE	
G90.2	Horner syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

Congenital or acquired

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Ptosis is usually mild. It results from loss of sympathetic tone to Müller muscle, which contributes approximately 2 mm of upper eyelid elevation. Weakness of the corresponding muscle in the lower eyelid causes it to elevate slightly. This combination causes narrowing of the palpebral fissure. Levator function of the eyelid is preserved.
- Miosis results from loss of sympathetic innervation to the iris dilator muscle. The affected pupil reacts normally to bright light and accommodation. Anisocoria is greater in dim light.
  1. Dilation lag: Horner pupil dilates more slowly than the normal pupil when lights are dimmed (20 vs. 5 sec) because it dilates passively as a result of relaxation of the iris sphincter.
- Presence of facial anhidrosis is variable and depends on the site of injury. It occurs with lesions affecting first-order or second-order neurons.
- Congenital Horner syndrome may result in heterochromia. The affected eye has a lighter-colored iris.
- Acute cases may also present with facial flushing, conjunctival injection, and nasal stuffiness from the loss of sympathetic vasoconstriction.

ETIOLOGY

Disruption of the ipsilateral sympathetic innervation to the eye and face. Lesions can damage any of the three neurons in the oculosympathetic pathway (Fig. E1). First-order neuron lesions are least common but are usually caused by pathology in the hypothalamus, brain stem, or cervicothoracic spinal cord. Second-order neuron lesions are often caused by disease involving the cervicothoracic spinal cord, lung apex, or anterior neck. Third-order neuron lesions are usually seen with disease in the internal carotid artery, skull base, cavernous sinus, or orbital apex. Location is often suggested by the presence of associated findings. Vascular disease and neoplasm must be considered.

One large study found that 65% of patients with Horner syndrome had an identifiable cause, 13% had a first-order neuron lesion, 44% had a second-order neuron lesion, and 43% had a third-order neuron lesion.

Mechanical:

- Syringomyelia
- Trauma
- Tumors: Benign, malignant head and neck cancers (thyroid, apical lung, mediastinal)
- Cervical rib

Vascular (ischemia, hemorrhage or arteriovenous malformation):

- Brain stem lesion: Commonly occlusion of the posterior inferior cerebellar artery but other arteries may be responsible (vertebral; superior, middle or inferior lateral medullary arteries; superior or anterior inferior cerebellar arteries)
- Carotid artery aneurysm, dissection, arteritis: Can also be from injury to other major vessels (internal carotid artery, subclavian artery, ascending aorta)
- Jugular venous ectasia
- Cavernous sinus thrombosis
- Cluster headache, migraine

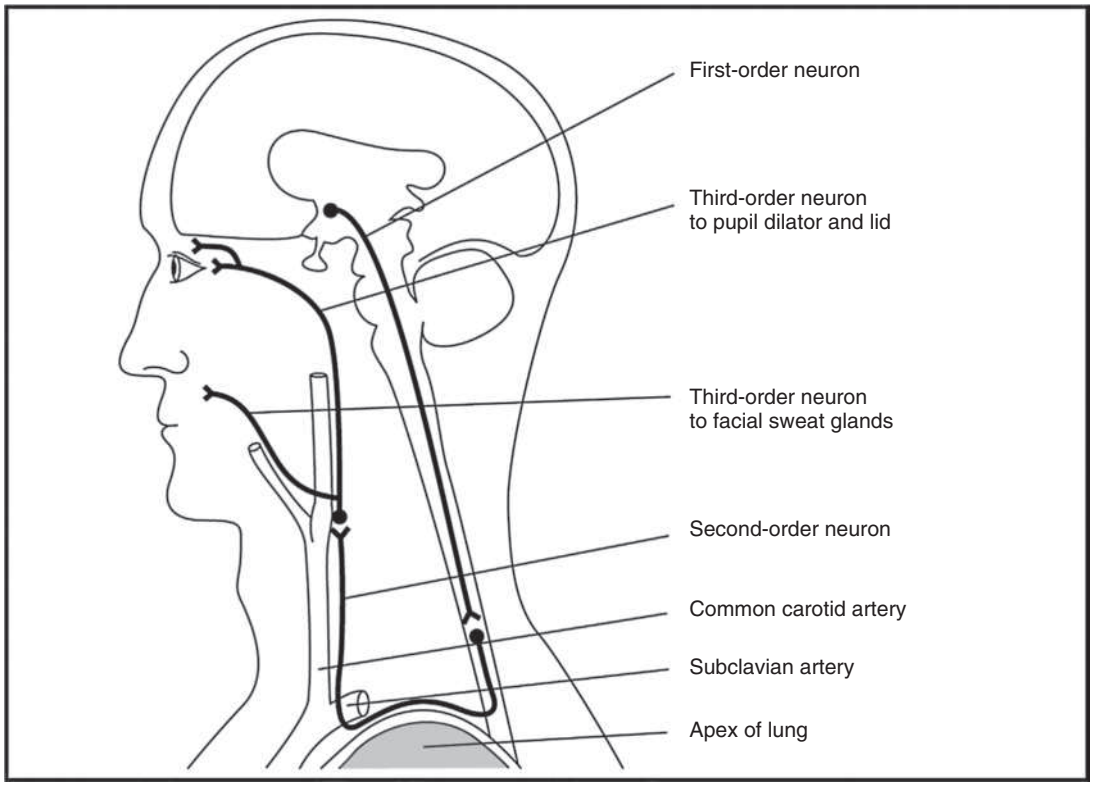

FIG. E1 Anatomy of sympathetic pathways to the eye. The sympathetic innervation of the eye consists of three neurons connected in a series: first-order neurons, second-order neurons, and third-order neurons. The first-order neurons (central neurons) extend from the posterior hypothalamus to the C8 to T2 level of the spinal cord. The second-order neurons (preganglionic neurons) leave the spinal cord and travel over the lung apex, around the subclavian artery, and along the carotid artery to the superior cervical ganglion. The third-order neurons (postganglionic neurons) diverge and take two paths: those to the pupil and lid muscles travel along the internal carotid artery through the cavernous sinus to reach the orbit; those to the facial sweat glands travel with the external carotid artery to the face. Lesions in any of these neurons cause Horner syndrome and distinct associated physical signs. (From McGee [ed]: *Evidence-based physical diagnosis,* ed 3, Philadelphia, 2012, WB Saunders.)

Miscellaneous:
- Idiopathic
- Congenital
- Demyelination (multiple sclerosis)
- Infection (apical tuberculosis, herpes zoster, Lyme disease)
- Myelitis
- Pneumothorax
- Iatrogenic (angiography, internal jugular/subclavian catheter, chest tube, neck or upper thoracic surgery, epidural spinal anesthesia)

DX DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Causes of anisocoria (unequal pupils):
- Normal variant
- Mydriatic use, medications
- Prosthetic eye
- Prior eye surgery, trauma
- Iritis
- Acute angle-closure glaucoma
- Adie tonic pupil
- Third nerve palsy

Causes of ptosis are described in Section II.

WORKUP

History, physical examination, pharmacologic testing, imaging

PHARMACOLOGIC TESTING

These medications may not be readily available. Pharmacologic testing should not delay evaluation in acute, painful, or traumatic cases or in patients with a history of malignancy.
- Topical cocaine test (Fig. E2): Confirms diagnosis (drops increase anisocoria by dilating normal pupil but not Horner pupil).
- Topical apraclonidine test: Confirms diagnosis (drops reverse anisocoria by causing dilation of Horner pupil and slight constriction of normal pupil). Less reliable than topical cocaine in acute Horner syndrome (Box E1).
- Topical hydroxyamphetamine test: Distinguishes first- and second-order neuron lesions from third-order sympathetic lesions (drops dilate normal pupil and first- or second-order Horner pupil, but not third-order Horner pupil). Testing must be delayed >48 hr after topical cocaine or apraclonidine testing.

IMAGING STUDIES

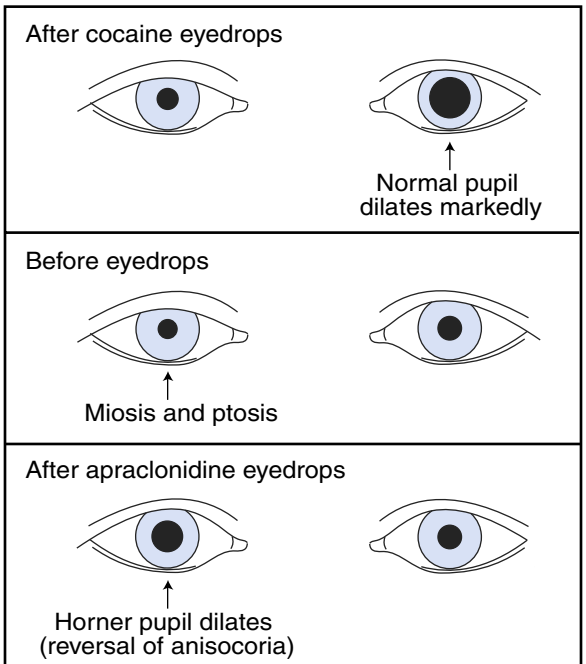
- One approach is to image the entire oculosympathetic pathway with an MRI of the brain to the upper chest and an MRA of the neck (or CT/CTA if acute presentation or MR not possible)
- Other approaches suggest using results of pharmacologic testing, as well as accompanying signs and symptoms to guide imaging
- MRI brain: Brain stem (diplopia, eye movement abnormalities, vertigo, ataxia, lateral medullary syndrome); cavernous sinus (sixth nerve palsy)
- MRI cervical and upper thoracic spinal cord: Sensory changes/weakness of extremities, bowel/bladder dysfunction
- MRI/MRA or CTA neck: Carotid artery dissection (acute Horner syndrome with face or neck pain)
- CT chest and neck: Evaluate lung apex, perivertebral areas, mediastinum if symptoms do not localize to the central nervous system; brachial plexus lesion (arm/hand pain or weakness)

RX TREATMENT

- Treatment depends on underlying cause.
- Ptosis can be surgically corrected or treated with medication (phenylephrine drops).

REFERRAL

Ophthalmologist for pharmacologic testing to confirm diagnosis and localize lesion



Eyedrop	Horner pupil	Normal pupil
Cocaine	No change	Dilates
Apraclonidine	Dilates	No change

FIG. E2 Confirmation of Horner syndrome: the cocaine and apraclonidine eyedrop tests. This patient has a right Horner syndrome with right miosis and ptosis *(middle row).* 45 min after installation of cocaine drops into each eye *(top row),* the Horner pupil fails to dilate, but the normal pupil dilates, markedly aggravating the anisocoria and confirming the diagnosis of Horner syndrome. 45 min after installation of apraclonidine drops into each eye (performed on a different day than the cocaine test; *bottom row*), the right Horner pupil dilates, but there is no response in the normal pupil, thus reversing the anisocoria and also confirming the diagnosis of Horner syndrome. Cocaine eyedrops block the reuptake of norepinephrine at the myoneural junction of the iris dilator, causing the pupil to dilate unless norepinephrine is absent because of sympathetic denervation. Apraclonidine eyedrops have no effect on normal pupils, but after sympathetic denervation from Horner syndrome, the affected pupil is supersensitive to their effect. Apraclonidine may also cause elevation of the lid in Horner syndrome *(bottom row),* although only the response of the pupil is used when interpreting the test. (From McGee S: *Evidence-based physical diagnosis,* ed 4, Philadelphia, 2018, Elsevier.)

BOX E1 Horner Syndrome, Eyedrop Tests

Finding (Reference)	Sensitivity (%)	Specificity (%)	LIKELIHOOD RATIO IF FINDING IS	
			Present	Absent
Detecting Horner Syndrome				
Anisocoria ≥1 mm after topical cocaine	95	99	**96.8**	**0.1**
Reversal of anisocoria after topical apraclonidine	95	90-95	**14.0**	**0.1**
Diagnosing First- or Second-Order Nerve Lesion in Horner Syndrome				
Small pupil dilates with topical hydroxyamphetamine (Paredrine)	83-92	79-96	**9.2**	**0.2**
Small pupil fails to dilate with dilute phenylephrine	88	79	**4.2**	NS
Asymmetric facial sweating	53	78	NS	0.6

NS, Not significant.
From McGee S: *Evidence-based physical diagnosis,* ed 4, Philadelphia, 2018, Elsevier.

PEARLS & CONSIDERATIONS

- May be the presentation of a life-threatening condition. Horner syndrome presenting acutely or associated with head/neck pain, trauma, or history of malignancy should be evaluated urgently.
- Normal variant anisocoria:
  1. Occurs in 20% of people
  2. Usually <1 mm difference between pupils
  3. Pupils are round and display a normal, brisk constriction and dilation response to light
- Infants with Horner syndrome may present with Harlequin sign, contralateral hemifacial flushing

BASIC INFORMATION

DEFINITION

Hot flashes are sudden onset of intense warmth that begins in the neck or face, or in the chest and progresses to the neck and face; often associated with profuse sweating, flushing, clamminess, anxiety, and palpitations.

SYNONYMS

HFs
Vasomotor symptoms (VMSs)
Hot flushes
Night sweats

ICD-10CM CODES

N95.1 Menopausal and female climacteric states
R23.2 Flushing

EPIDEMIOLOGY & DEMOGRAPHICS

- Hot flashes affect up to 75% of women who are in the menopausal transition.
- Hot flashes typically start during late perimenopause, increase in frequency and severity throughout the menopausal transition, and finally decline over time after the final menstrual period.
- Median total duration of hot flashes is 7 yr, with symptoms lasting for a median of 4.5 yr after the last menstrual period. Women who have hot flashes early in the menopause transition can experience symptoms for more than 12 yr.
- Prevalence of hot flashes differs among racial and ethnic groups in the U.S. with highest frequency among African American women and lowest frequency among Chinese and Japanese women.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Profuse sweating and red blotching of skin may be noted during the vasomotor event.
- Palpitations and hyperreflexia may be present during the hot flash.
- Hot flashes typically last 1 to 5 min.
- Each hot flash is associated with increase in temperature, increased pulse rate, and increased blood flow into the hands and face.
- Hot flashes during sleep are common and are referred to as *night sweats*.
- There is considerable variation in the frequency of hot flashes. One third of women report more than 10 flashes per day.

ETIOLOGY

- Dysfunction of central thermoregulatory centers caused by reduction of estrogen levels at the time of menopause
- Tamoxifen use
- Chemotherapy-induced ovarian failure
- Androgen ablation therapy for prostate carcinoma

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Carcinoid syndrome
- Anxiety disorder
- Idiopathic flushing
- Malignancy (lymphoma, solid tumors)
- Hyperthyroidism
- Hyperhidrosis
- Infection

WORKUP

Evaluation of hot flashes is aimed at excluding the conditions listed in the differential diagnosis.

LABORATORY TESTS

- Follicle-stimulating hormone (FSH), luteinizing hormone, estradiol level. The serum FSH levels rather than estradiol levels are associated with greater severity of hot flashes in older postmenopausal women, suggesting that nonestrogen feedback systems may be important in modulating the severity of hot flashes. It is not necessary to obtain an FSH to make the diagnosis of menopausal status, however. An amenorrheic woman over age 50 with vasomotor symptoms is assumed to have made the menopausal transition, and serum markers of menopause are not required to complete the diagnosis.
- Thyroid-stimulating hormone (TSH).

TREATMENT

NONPHARMACOLOGIC THERAPY

- Behavioral interventions such as relaxation training and paced respiration have been reported effective in reducing symptoms in some women.
- Lifestyle changes such as maintaining a healthy body weight, exercising regularly, and avoiding caffeine, alcohol, tobacco, and spicy foods may be beneficial.

ACUTE GENERAL Rx

- Systemic hormone therapy with estrogen alone or in combination with progestin is the most effective way to manage menopausal hot flashes with up to a 75% reduction in weekly episodes. Women receiving hormone therapy are at increased risk of thromboembolic disease and breast cancer; therefore, use should be limited to the shortest duration and smallest possible dose to control symptoms, and only after considering potential risks and benefits for each individual patient.
- While there is some evidence that progestin-only medications may improve hot flashes, it is not considered first-line treatment for vasomotor symptom management.
- The only nonhormonal method that is FDA-approved for management of hot flashes is the SSRI paroxetine (7.5 mg daily). Other antidepressants shown to be effective for treatment of hot flashes include escitalopram (10 mg to 20 mg per day), venlafaxine (37.5 mg to 75 mg per day), and desvenlafaxine (100 mg to 150 mg per day). Caution should be taken in prescribing SSRIs and SNRIs in women taking tamoxifen, as these antidepressants interfere with the cytochrome P-450 metabolism of tamoxifen, reducing its efficacy.
- Duavee is a new FDA-approved treatment of moderate to severe vasomotor menopausal symptoms. It consists of a combination of conjugated estrogens and bazedoxifene, a new selective estrogen receptor modulator (SERM).
- The anticonvulsant gabapentin (300-1200 mg/day) represents another nonhormonal alternative in the treatment of hot flashes. It can be used alone or in combination with an antidepressant; however, combining the two medications does not appear to be more effective than just gabapentin alone.
- The antihypertensive clonidine is also somewhat effective in reducing the frequency of hot flashes in mild cases. Adverse effects include dry mouth, sedation, and dizziness.
- Recent trials with the anti-cholinergic drug oxybutynin have shown effectiveness in reducing the frequency and severity of hot flashes in women with a history of breast cancer.
- Vitamin E (800 IU/day) may be effective in patients with mild symptoms that do not interfere with sleep or daily function.
- Soy protein (use of soy extracts that contain plant-derived estrogens [phytoestrogens]) is often used; however, clinical trials have not shown clear efficacy.
- Several classes of herbal remedies are available to patients and are commonly used, generally without significant benefit. Frequently used agents are *Cimicifuga racemosa* (black cohosh, snakeroot, bugbane), *Angelica sinensis,* and evening primrose (evening star). Recent trials using the isopropanolic extract of black cohosh rootstock (Remifemin) did show some improvement in controlling menopausal symptoms. Such alternative medications may be used to treat mild to moderate symptoms, but it is possible that symptomatic improvements may derive in part from a placebo effect. Acupuncturists are the second most consulted therapists by menopausal women. Evidence of acupuncture efficacy as an HF treatment is conflicting. A recent randomized trial[1] revealed that Chinese medicine acupuncture was not superior to noninsertive sham acupuncture for women with moderately severe menopausal HFs.

BASIC INFORMATION

DEFINITION

The human immunodeficiency virus (HIV) is a retrovirus that is responsible for causing acquired immunodeficiency syndrome (AIDS). HIV infection does not necessarily mean a person has AIDS. Table 1 summarizes surveillance case definition for HIV.

SYNONYMS

HIV

AIDS: The result of progressive HIV infection in which a person has a weakened immune system and meets specific diagnostic criteria (See "Acquired Immunodeficiency Syndrome" in Section I and Table 2.)

EPIDEMIOLOGY & DEMOGRAPHICS (IN U.S.)

- An estimated 1.1 million people in the United States are infected with HIV, and approximately 14% of them do not know they are infected.
- In 2018, there were approximately 38,000 new HIV diagnoses, according to the Centers for Disease Control and Prevention (CDC).
- Incidence is highest among gay, bisexual, and other men who have sex with men (MSM) and in minority racial and ethnic populations.

PREDOMINANT RISK GROUPS:

- Gay, bisexual, and other MSM is the group most affected by HIV.
- In 2017, MSM accounted for approximately 67% of all new diagnoses, according to the CDC.
- HIV disproportionately affects MSM of younger age and black/African American and Hispanic/Latino background.
- Heterosexual transmission and injection drug use accounted for 24% and 6%, respectively, of new HIV diagnoses in 2017.
- Table 3 summarizes risk factors associated with sexual transmission of HIV.

RACIAL DATA:

- In 2017, individuals of African American descent accounted for 43% of new HIV diagnoses despite being 12% of the U.S. population.
- In 2016, Hispanics/Latinos accounted for 26% of new HIV diagnoses despite being 18% of the U.S. population.

GENETICS:

Familial Disposition:

Individuals with deletions in the *CCR5* gene are immune from infection with macrophage tropic virus (the predominant virus in sexual transmission). Other genetic variants may contribute to rapid progression or long-term control of the virus once infected. One in 300 individuals infected with HIV is an "elite controller," which means they are able to maintain a normal CD4 count and undetectable viral load through immune control.

Congenital Infection:

- In 2017, 73 children younger than 13 yr received a diagnosis of perinatally acquired HIV, according to the CDC, which may occur in utero, during delivery, or after delivery via breastfeeding.
- No specific congenital abnormalities are associated with HIV infection, although there is a higher risk of spontaneous abortion and low birth weight.

Neonatal Infection:

- May occur during delivery or via breastfeeding.
- Typically asymptomatic.
- All pregnant women should be tested for HIV and, if positive, take antiretrovirals (ARVs).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Signs and symptoms are variable with stage of disease.
- Acute HIV infection (0 to 3 mo, usually within several weeks):
  1. Causes a self-limited mononucleosis-like illness in 50% to 80% of individuals, characterized by fever, sore throat, lymphadenopathy, headache, and a rash resembling roseola. Individuals may also be asymptomatic.
  2. In a minority of acute cases, aseptic meningitis, Bell palsy, or peripheral neuropathy may occur.
  3. Opportunistic infections such as thrush or *Pneumocystis jiroveci* pneumonia (PJP) may occur.
- Chronic HIV infection is usually characterized by a prolonged asymptomatic "latent" phase without symptoms followed by nonspecific symptoms of lymphadenopathy, fatigue, weight loss, diarrhea, and skin changes,

TABLE 1 Surveillance Case Definition for HIV Infection in Adults and Adolescents (Age >13 yr)

Stage	Laboratory Evidence	Clinical Evidence
Stage 1	Laboratory confirmation of HIV infection and CD4+ T-lymphocyte count of ≥500 cells/μL or CD4+ T-lymphocyte percentage of ≥ 29%[a]	No AIDS-defining condition (see Table 2)
Stage 2	Laboratory confirmation of HIV infection and CD4+ T-lymphocyte count of 200-499 cells/μL or CD4+ T-lymphocyte percentage of 14%-28%[a]	No AIDS-defining condition (see Table 2)
Stage 3	Laboratory confirmation of HIV infection and CD4+ T-lymphocyte count of <200 cells/μL or CD4+ T-lymphocyte percentage of <14%[a]	Documentation of an AIDS-defining condition with laboratory confirmation of HIV infection (see Table 2)
Stage unknown	Laboratory confirmation of HIV infection and no information on CD4+ T-lymphocyte count or percentage	No information on presence of an AIDS-defining condition

[a]The CD4+ T-lymphocyte percentage is a percentage of the total lymphocyte count.

TABLE 2 Surveillance Definitions of AIDS-Defining Conditions

Opportunistic Infections:

- *Pneumocystis jiroveci (carinii)*
- *Mycobacterium avium* complex
- *Mycobacterium tuberculosis*
- Toxoplasmosis
- Candidiasis: Esophageal and systemic
- Histoplasmosis
- Cryptococcosis
- Cryptosporidiosis and isosporiasis
- Leishmaniasis
- Cytomegalovirus disease
- Recurrent bacterial infections (≥2 episodes/yr)

Lymphomas

Kaposi Sarcoma

Cervical Cancer

AIDS Dementia Syndrome

Wasting Syndrome

From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE 3 Risk Factors Associated with Sexual Transmission of HIV

- Sexually transmitted infections
  - Ulcerative or nonulcerative diseases
- Genital tract inflammation
- HIV disease
  - Higher viral loads
  - Lower CD4+ levels
  - Acute HIV infection
  - Lack of effective antiretroviral therapy
  - Lack of heterozygosity or homozygosity for the inactivating 32-base pair deletion in the chemokine receptor gene *(CCR5)*
- Anatomic factors
  - Lack of circumcision
  - Cervical ectopy
  - Leukocytospermia
  - Hormonal contraception
- Sexual practices
  - Receptive anal intercourse
  - Sexual activity during menses
  - Bleeding during intercourse (disruption of vaginal mucosa through trauma)
  - Lack of barrier protection
- HIV viral features
  - Syncytium formation
  - Certain viral clades

From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.

TABLE 4 Etiology of Anemia in Human Immunodeficiency Virus

HIV Related

HIV Infection

- Anemia of chronic disease
- Blunted production/response to erythropoietin
- Suppression of CFU-GEMM (HIV/inflammatory cytokines)

Neoplasms Infiltrating BM

Non-Hodgkin lymphoma, KS, Hodgkin lymphoma

Infections of the BM

- Parvovirus B19
- Atypical mycobacteria (MAI/MAC)
- M. TB
- Histoplasma
- CMV

Medications Causing Decreased Production	Medications Causing Hemolysis
• RT inhibitors • Ganciclovir • Bactrim • Amphotericin B	• Indinavir • Bactrim and Dapsone in G6PD deficiency

HIV Unrelated

- B_{12} and/or folic acid deficiencies
- Iron deficiency caused by chronic blood loss

BM, Bone marrow; *CFU-GEMM,* colony-forming unit–granulocyte, erythrocyte, macrophage, megakaryocyte; *CMV,* cytomegalovirus; *G6PD,* glucose-6-phosphate dehydrogenase; *KS,* Kaposi sarcoma; *MAC,* mycobacterium avium complex; *MAI,* mycobacterium avium-intracellulare; *M. TB, Mycobacterium tuberculosis*; *RT,* reverse transcriptase.

From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

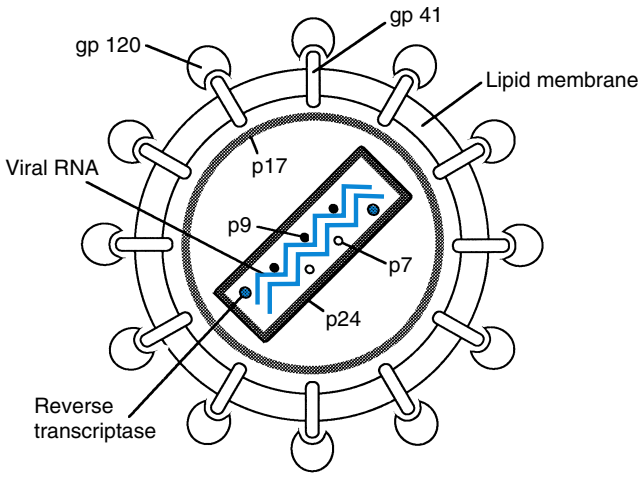

FIG. 1 Structure of the human immunodeficiency virus virion. Two coding strands of genomic ribonucleic acid (RNA) are packaged in the nucleoid core with p7, p9, and p24 proteins and reverse transcriptase. The core is surrounded by the p17 matrix protein lining the inner surface of the envelope. The envelope consists of a lipid bilayer derived from the infected cell and glycoprotein spikes that consist of the outer glycoprotein (GP) 120 molecule, which contains the binding site for CD4, and GP41, which anchors the glycoprotein complex to the envelope and mediates fusion of the viral membrane with the cell membrane during viral penetration. (From Hoffman R et al: *Hematology: basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

including seborrheic dermatitis, localized herpes zoster, and/or fungal infection.

- Advanced disease is characterized by AIDS-associated diseases, including infections and malignancies (see specific disorders). Anemia may be multifactorial (Table 4).
- HIV infection in women may be associated with lower levels of viral load at comparable degrees of immunosuppression when compared with men. Furthermore, women may, on average, have higher CD4 counts at the time of HIV diagnosis.
- Another special consideration in women infected with HIV is the high incidence of human papillomavirus (HPV) co-infection and risk for cervical cancer. HIV-positive women should be screened for cervical cancer at time of initial HIV diagnosis and annually thereafter if pap testing is normal. If the results of three consecutive Pap tests are normal, then follow-up testing can occur every 3 yr. HPV vaccination is also recommended in men and women 9- to 26-yr-old who are HIV positive.
- Co-infection with HIV and hepatitis C virus is common because of similar transmission risk. Hepatitis C is most commonly transmitted by contaminated needles or blood exposure. Hepatitis C can be transmitted sexually, but the risk is low. Patients with HIV and hepatitis C progress faster to cirrhosis. Patients may already have signs of advanced liver disease at the time of diagnosis.

ETIOLOGY

- HIV is a single-stranded RNA retrovirus (Fig. 1) that is categorized as type 1 or 2.
- HIV-1 was derived from transmission of a simian immunodeficiency virus (SIV) from chimpanzees in Central Africa; HIV-2 was derived from an SIV found in sooty mangabey monkeys from West Africa.
- HIV-1 is the predominant pathogenic retrovirus in human populations; HIV-2 has limited distribution (primarily West Africa) and tends to progress less rapidly than HIV-1. HIV-2 should be considered in individuals from West Africa or whose sexual partners are from West Africa.
- HIV is transmitted by sexual contact, shared needles, blood transfusion, or from mother to child during pregnancy, delivery, or breastfeeding.
- Primary target of infection: CD4 lymphocytes.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute HIV infection: Often diagnosed or confused with mononucleosis or other respiratory viral infections.
- Late symptoms: Similar to those produced by other wasting/chronic illnesses such as neoplasms, tuberculosis (TB), disseminated fungal infection (such as *Candida*), malabsorption, or depression.
- HIV-related encephalopathy: Confused with Alzheimer disease or other causes of chronic dementia (cognitive impairment in HIV infection is described in another chapter in Section I); myelopathy and neuropathy possibly resembling other demyelinating diseases such as multiple sclerosis.
- Direct central nervous system (CNS) involvement: Manifests as encephalopathy, myelopathy, or neuropathy in advanced cases. Table 5 summarizes neuromuscular syndromes in HIV infection.
- Renal failure, rheumatologic disorders, thrombocytopenia, or cardiac abnormalities (Table 6) may be seen in association with HIV-1.

WORKUP

Diagnosis is established by testing for HIV antibodies in the blood. The CDC recommends routine testing for patients in all health care settings unless the patient declines (opt-out screening). This includes routine testing of pregnant women. It is also recommended that separate written consent should no longer be required, although by law this is being addressed on a state-by-state basis. Generally, all persons aged 13 to 64 yr should undergo HIV testing at least once, and more frequently (at least once a yr) if sexually active. For individuals who may be at higher risk (e.g., men who are having sex with multiple other men), 3 to 6 mo is recommended.

An FDA-approved at-home rapid HIV screening test is available. It uses swabs of oral fluids from upper and lower gums. A positive test requires confirmatory testing.

LABORATORY TESTS

HIV antibodies are detected by a two-step technique:

- An initial screening test (i.e., enzyme-linked immunosorbent assay [ELISA]).
- Confirmation of an initial positive screening test with more specific assays. The classic confirmatory test is the western blot, but other modalities may be used. Fig. E2 summarizes the laboratory diagnosis of HIV infection.

TABLE 5 Neuromuscular Syndromes in Human Immunodeficiency Virus Type 1 Infection

Diagnosis	Disease Stage	Clinical Features	Diagnostic Studies	Treatment
AIDP	Early > late	Weakness more than sensory loss	CSF: ↑ WBCs	Early: IVIG, steroids, plasmapheresis
CIDP			↑↑ Protein	Late: Consider ganciclovir/foscarnet
			NCS: Demyelination	
MM	Early or late	Multiple painful mononeuropathies	NCS: Multifocal axonal neuropathy	Early: None
			Biopsy: Inflammation/vasculitis	Late: Steroids/cyclophosphamide
			CMV	Ganciclovir/foscarnet
Nucleoside	Any stage	Distal sensory loss	NCS: Distal axonopathy	Nucleoside withdrawal
Neuropathy		Neuropathic pain	Increased serum lactate	
DSPN	Late	Distal sensory loss	NCS: Distal axonopathy	NSAIDs, capsaicin
		Neuropathic pain		AED, tricyclics
PP	Late	Progressive flaccid paraparesis, urinary dysfunction, LS pain	CSF: Increased WBCs (PMNs), CMV PCR+	Ganciclovir/foscarnet Cidofovir
DILS	Late	Sjögren syndrome, distal motor and sensory loss, pain	NCS: Axonal neuropathyBiopsy: $CD8^+$ T cells, HIV-1	Zidovudine/ART Steroids
Zidovudine	Any stage	Proximal weakness	EMG: ± irritative	Zidovudine withdrawal
Myopathy		Myalgias	Biopsy: Ragged red fibers	
Polymyositis	Any stage	Proximal weakness	EMG: ± irritative	Steroids, IVIG
		Myalgias	Biopsy: Inflammatory infiltrates	Immunosuppressants
ALS-like	Late	Weakness, dysphagia	EMG: Neurogenic	ART

AED, Antiepileptic drug; *AIDP,* acute inflammatory demyelinating polyneuropathy; *ALS,* amyotrophic lateral sclerosis; *ART,* antiretroviral therapy; *CIDP,* chronic inflammatory demyelinating polyneuropathy; *CMV,* cytomegalovirus; *CSF,* cerebrospinal fluid; *DILS,* diffuse infiltrative lymphocytosis syndrome; *DSPN,* distal sensory polyneuropathy; *EMG,* electromyography; *IVIG,* intravenous immunoglobulin; *LS,* lumbosacral; *MM,* mononeuritis multiplex; *NCS,* nerve conduction studies; *NSAID,* nonsteroidal antiinflammatory drug; *PCR,* polymerase chain reaction; *PMNs,* polymorphonuclear leukocytes; *PP,* progressive polyradiculopathy; *WBCs,* white blood cells.

From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.

TABLE 6 Summary of HIV-Associated Cardiovascular Diseases

Disease	Possible Causes	Incidence/Prevalence	Diagnosis	Treatment
Accelerated atherosclerosis	Protease inhibitors, atherogenesis with virus-infected macrophages, chronic inflammation, glucose intolerance, dyslipidemia, endothelial dysfunction	Up to 8%	ECG, stress testing, echocardiography, lipid profile, CT angiography, calcium scoring	Smoking cessation, low-fat diet, aerobic exercise, blood pressure control, guideline-based statin use, percutaneous coronary intervention, coronary artery bypass surgery
Dilated cardiomyopathy	Coronary artery disease	Up to 8% of asymptomatic patients	Chest radiographic findings	Diuretics, digoxin, ACE inhibitors, beta blockers
LV systolic dysfunction	Drug related: Cocaine, AZT, IL-2, doxorubicin, interferon Infectious: HIV, *Toxoplasma*, coxsackievirus group B, EBV, CMV, adenovirus Metabolic or endocrine: selenium or carnitine deficiency, anemia, hypocalcemia, hypophosphatemia, hyponatremia, hypokalemia, hypoalbuminemia, hypothyroidism, growth hormone deficiency, adrenal insufficiency, hyperinsulinemia Cytokines: TNF-β, nitric oxide, TGF-β, endothelin-1, interleukins Immunodeficiency: CD4 count <100 Autoimmune	Up to 25% of autopsy cases	ECG: Nonspecific conduction abnormalities, PVCs, PACs Echocardiographic findings: Low to normal LV wall thickness, increased LV mass, LV dilation, systolic LV dysfunction Possible laboratory studies: Troponin T, brain natriuretic peptide concentration, CD4 count, viral load, viral PCR, *Toxoplasma* serology, thyroid-stimulating hormone, cortisol, carnitine, selenium, serum ACE, stress testing, myocardial biopsy, cardiac catheterization	Adjunctive treatment in HIV patients Treatment of infection Nutritional replacement IVIG Intensify antiretroviral therapy Follow-up serial echocardiograms
LV diastolic dysfunction	TNF, IL-6 Hypertension Chronic viral infection	Up to 37% asymptomatic	Echocardiography Tissue Doppler imaging	Treat hypertension Intensify antiretroviral therapy

TABLE 6 Summary of HIV-Associated Cardiovascular Diseases—cont'd

Disease	Possible Causes	Incidence/Prevalence	Diagnosis	Treatment
Primary pulmonary hypertension	Plexogenic pulmonary arteriopathy	0.5%	ECG, echocardiography, right-heart catheterization	Anticoagulation, vasodilators, prostacyclin analogues Endothelin antagonists PDE-5 inhibitors
Pericardial	Bacteria: *Staphylococcus*, *Streptococcus*, *Proteus*, *Klebsiella*, *Enterococcus*, *Listeria*, *Nocardia*, *Mycobacterium* Viral pathogens: HIV, HSV, CMV, adenovirus, echovirus Other pathogens: *Cryptococcus*, *Toxoplasma*, *Histoplasma* Malignancy: Kaposi sarcoma, lymphoma, capillary leak/wasting/malnutrition Hypothyroidism Immunodeficiency Uremia	11%/yr, markedly reduced in post-HAART studies Spontaneous resolution in 42% of affected patients Approximately 30% increase in 6-mo mortality	Pericardial rub on examination Echocardiography Fluid analysis for Gram stain, culture, and cytology ECG—low voltage/PR depression Associated pleural and peritoneal fluid analysis Pericardial biopsy	Treat the cause Follow-up: Serial echocardiograms Intensify antiretroviral therapy Pericardiocentesis or window
Infective endocarditis	Autoimmune Bacteria: *Staphylococcus aureus* or *Staphylococcus epidermidis*, *Salmonella*, *Streptococcus*, *Haemophilus parainfluenzae*, *Pseudallescheria boydii*, HASEK organisms Fungal: *Aspergillus fumigatus*, *Candida*, *Cryptococcus neoformans*	6% increased incidence in IVDAs, regardless of HIV status	Blood cultures; echocardiography	Intravenous antibiotics, valve replacements
Nonbacterial thrombotic endocarditis	Valvular damage, vitamin C deficiency, malnutrition, wasting, DIC, hypercoagulable state, prolonged acquired immunodeficiency	Rare condition, but clinically relevant emboli in 42% of cases	Echocardiography	Anticoagulation Treat vasculitis or underlying illness
Malignancy	Kaposi sarcoma, non-Hodgkin lymphoma, leiomyosarcoma, low CD4 count, prolonged immunodeficiency HHV-8, EBV	Approximately 1% Usually metastatic in HIV-positive patients	Echocardiography, biopsy	Chemotherapy possible
Right ventricular disease	Recurrent pulmonary infections, pulmonary arteritis, microvascular pulmonary emboli, COPD		ECG, echocardiography, right-heart catheterization	Diuretics, treat underlying lung infection or disease, anticoagulation as clinically indicated
Vasculitis	Drug therapy with antibiotics and antivirals	Increasing incidence	Clinical diagnosis	Systemic corticosteroids, withdrawal of drug
Autonomic dysfunction	CNS disease, drug therapy, prolonged immunodeficiency, malnutrition, sedentary lifestyle	Increased in patients with CNS disease	Tilt-table test, Holter or event monitoring	Procedural precautions
Arrhythmias	Drug therapy, pentamidine, autonomic dysfunction, acidosis electrolyte abnormalities		ECG—long QT, Holter monitoring, exercise stress testing	Discontinue drug, procedural precautions, electrolyte replacement
Lipodystrophy	Drug therapy: Protease inhibitors		Echocardiography, lipid profile, cardiac catheterization, coronary calcium score	Lipid therapy (beware of drug interactions), aerobic exercise, altered antiretroviral therapy, cosmetic surgery/fat implantation

ACE, Angiotensin-converting enzyme; *AZT,* zidovudine (azidothymidine); *CMV,* cytomegalovirus; *CNS,* central nervous system; *COPD,* chronic obstructive pulmonary disease; *CT,* computed tomography; *DIC,* disseminated intravascular coagulation; *EBV,* Epstein-Barr virus; *ECG,* electrocardiogram; *HAART,* highly active antiretroviral therapy; *HASEK, Haemophilus* species (*Haemophilus parainfluenzae*, *Haemophilus aphrophilus*, *Haemophilus paraphrophilus*), *Actinobacillus actinomycetemcomitans*, *Cardiobacterium hominis*, *Eikenella corrodens*, and *Kingella* species; *HHV,* human herpesvirus; *HSV,* herpes simplex virus; *IL,* interleukin; *IVDA,* intravenous drug abuser; *IVIG,* intravenous immunoglobulin; *LV,* left ventricle; *PAC,* premature atrial complex; *PCR,* polymerase chain reaction; *PDE,* phosphodiesterase; *PVC,* premature ventricular complex; *TGF,* transforming growth factor; *TNF,* tumor necrosis factor.

From Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.

- Screening antibody tests generally measure HIV-1 and HIV-2 antibodies. Confirmatory tests will generally differentiate between HIV-1 and HIV-2 as well. However, the viral load assays (HIV RNA PCR) are specific only for HIV-1.
- Fourth-generation antibody/antigen tests can detect the "p24" antigen, which is present early in HIV infection and can be used to diagnose HIV earlier than previous generations. An HIV RNA PCR should still be sent if acute HIV is suspected.
- Baseline viral resistance testing (e.g., genotype) is recommended for all newly diagnosed patients with HIV to guide choice of ART.
- The CD4 count and HIV viral load (e.g., HIV RNA PCR) should be measured in all patients.
- The CD4 count is a marker of current immune status. Table 7 describes the World Health Organization (WHO) immunologic classification for established HIV infection.
- The HIV RNA PCR (viral load) is predictive of disease progression.

- Rapid serologic tests have been increasingly used and are useful in specific settings: Occupational exposures, pregnant women in labor without previous testing, and patients in high seroprevalence areas (for immediate results). Specimens are either blood or saliva and results are given within 1 to 20 min. Although sensitivity is high (99%), false-positive tests are more common in low seroprevalence populations. Thus, all positive results must be confirmed with standard serology.
- Early during infection (i.e., acute HIV infection), standard antibody tests may be negative ("window period"). The fourth-generation antibody/antigen test reduces this window period. The standard for diagnosing HIV during acute infection is by testing for HIV RNA (viral load).
- In 2014, the CDC released a revised surveillance case definition for HIV infection. This information has been added in the EBM section of this topic. Table 8 describes the WHO clinical staging of HIV/AIDS for adults and adolescents with confirmed HIV infection. Table 9 compares the WHO and CDC staging systems.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Maintenance of adequate nutrition

ACUTE GENERAL Rx

Acute management of opportunistic infections and malignancies (see AIDS-associated disorders, "Pneumonia, Pneumocystis jiroveci (carinii);" "Cryptococcosis;" "Tuberculosis, Pulmonary;" "Cryptosporidium Infection;" "Toxoplasmosis;" etc., elsewhere in this text)

TABLE 7 World Health Organization Immunologic Classification for Established HIV Infection

HIV-Associated Immunodeficiency	Age-Related CD4 Values			
	<11 mo (% $CD4^+$)	12-35 mo (% $CD4^+$)	36-59 mo (% $CD4^+$)	>5 yr (Absolute No./mm^3 or % $CD4^+$)
None or not significant	>35	>30	>25	>500
Mild	30-35	25-30	20-25	350-500
Advanced	25-29	20-24	15-19	200-349
Severe	<25	<20	<15	<200 or <15%

TABLE 8 World Health Organization Clinical Staging of HIV/AIDS for Adults and Adolescents with Confirmed HIV Infection

Clinical Stage 1
Asymptomatic
Persistent generalized lymphadenopathy
Clinical Stage 2
Moderate unexplained weight loss (<10% of presumed or measured body weight)*
Recurrent respiratory tract infections (e.g., sinusitis, tonsillitis, otitis media, pharyngitis)
Herpes zoster
Angular cheilitis
Recurrent oral ulceration
Papular pruritic eruptions
Seborrheic dermatitis
Fungal nail infections
Clinical Stage 3
Unexplained* severe weight loss (>10% of presumed or measured body weight)
Unexplained chronic diarrhea for longer than 1 month
Unexplained persistent fever (>37.6 °C [99.7 °F]), intermittent or constant, for longer than 1 mo
Persistent oral candidiasis
Oral hairy leukoplakia
Pulmonary tuberculosis (current)
Severe bacterial infections (e.g., pneumonia, empyema, pyomyositis, bone or joint infection, meningitis, or bacteremia)
Acute necrotizing ulcerative stomatitis, gingivitis, or periodontitis
Unexplained anemia (<8 g/dl), neutropenia ($<0.5 \times 10^9$/L), or chronic thrombocytopenia ($<50 \times 10^9$/L)
Clinical Stage 4†
HIV wasting syndrome
Pneumocystis jiroveci
Recurrent severe bacterial pneumonia
Chronic herpes simplex infection (orolabial, genital or anorectal, longer than 1 month's duration, or visceral at any site)
Esophageal candidiasis (or candidiasis of trachea, bronchi, or lungs)
Extrapulmonary tuberculosis
Kaposi sarcoma
Cytomegalovirus infection (retinitis or infection of other organs)

TABLE 8 World Health Organization Clinical Staging of HIV/AIDS for Adults and Adolescents with Confirmed HIV Infection—cont'd

Central nervous system toxoplasmosis
HIV encephalopathy
Extrapulmonary cryptococcosis, including meningitis
Disseminated nontuberculous mycobacterial infection
Progressive multifocal leukoencephalopathy
Chronic cryptosporidiosis (with diarrhea)
Chronic isosporiasis
Disseminated mycosis (coccidioidomycosis or histoplasmosis)
Recurrent nontyphoidal *Salmonella* bacteremia
Lymphoma (cerebral or B-cell non-Hodgkin) or other solid HIV-associated tumors
Invasive cervical carcinoma
Atypical disseminated leishmaniasis
Symptomatic HIV-associated nephropathy or symptomatic HIV-associated cardiomyopathy

AIDS, Acquired immunodeficiency syndrome.
*Unexplained refers to when the condition is not explained by other causes.
†Some additional specific conditions can also be included in regional classifications (e.g., reactivation of American trypanosomiasis [meningoencephalitis or myocarditis]) in the World Health Organization region of the Americas and disseminated penicilliosis in Asia.
From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.

TABLE 9 Comparison of WHO and CDC Staging Systems*

WHO Stage†	WHO T-Lymphocyte Count and Percentage‡	CDC Stage§	CDC T-Lymphocyte Count and Percentage
Stage 1 (HIV infection)	$CD4^+$ T-lymphocyte count of ≥500 cells/mm^3	Stage 1 (HIV infection)	$CD4^+$ T-lymphocyte count of ≥500 cells/mm^3 or $CD4^+$ T-lymphocyte percentage of ≥29
Stage 2 (HIV infection)	$CD4^+$ T-lymphocyte count of 350-499 cells/mm^3	Stage 2 (HIV infection)	$CD4^+$ T-lymphocyte count of 200-499 cells/mm^3 or $CD4^+$ T-lymphocyte percentage of 14-28
Stage 3 (advanced HIV disease [AHD])	$CD4^+$ T-lymphocyte count of 200-349 cells/mm^3	Stage 2 (HIV infection)	$CD4^+$ T-lymphocyte count of 200-499 cells/mm^3 or $CD4^+$ T-lymphocyte percentage of 14-28
Stage 4 (acquired immunodeficiency syndrome [AIDS])	$CD4^+$ T-lymphocyte count of <200 cells/mm^3 or $CD4^+$ T-lymphocyte percentage of <15	Stage 3 (AIDS)	$CD4^+$ T-lymphocyte count of <200 cells/mm^3 or $CD4^+$ T-lymphocyte percentage of <14

CDC, Centers for Disease Control and Prevention; *WHO,* World Health Organization.
*For reporting purposes only.
†Among adults and children aged ≥5 yr.
‡Percentage applicable for stage 4 only.
§Among adults and adolescents (ages ≥13 yr). CDC also includes a fourth stage, stage unknown; laboratory confirmation of HIV infection but no information on $CD4^+$ T-lymphocyte count or percentage and no information on AIDS-defining conditions.
From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.

CHRONIC Rx

All HIV-infected patients should be considered for ART regardless of CD4 cell count. The benefit of ART is well established in preventing progression to AIDS and associated comorbidities. Furthermore, individuals who are on ART and undetectable are highly unlikely to transmit HIV to others. Identifying individuals with HIV as soon as possible and administering ART is the basis of effective public health approaches to addressing HIV (i.e., "Treatment as Prevention").

- Therapy is strongly recommended for all patients with symptomatic established HIV disease regardless of the CD4 count. Symptomatic HIV disease is defined as the presence of any of the following: thrush, vaginal candidiasis, herpes zoster, peripheral neuropathy, bacillary angiomatosis, cervical dysplasia in situ, constitutional symptoms such as fever or diarrhea for more than 1 month, ITP, PID, or listeriosis.
- In asymptomatic individuals, ART is recommended regardless of CD4 cell counts. The recommendations are due to the safety and benefit of newer antivirals in preventing AIDS and decreasing both morbidity and mortality. Earlier treatment may also help reduce transmission of the virus to others due to reductions in viral loads.
- ART generally consists of using a 3-drug regimen to treat HIV infection. Classes of antiretrovirals include:
  1. Nucleoside/nucleotide reverse transcriptase inhibitor (NRTI): Zidovudine (AZT), lamivudine (3TC), emtricitabine (FTC), tenofovir disoproxil fumarate (TDF), tenofovir alafenamide (TAF), abacavir (ABC), stavudine (D4T), or didanosine (DDI).
  2. Protease inhibitors (PI): Lopinavir/ritonavir, atazanavir, fosamprenavir, darunavir, saquinavir, amprenavir, tipranavir, nelfinavir, and indinavir. These PIs may be "boosted" by ritonavir or cobicistat to increase levels.
  3. Non-nucleoside reverse transcriptase inhibitors (NNRTI): Nevirapine, efavirenz, etravirine, delavirdine, or rilpivirine.
  4. Integrase inhibitors (II): Raltegravir, elvitegravir, bictegravir, and dolutegravir.
  5. Fusion inhibitors: Enfuvirtide (T-20). This drug is administered through subcutaneous injections and is only used as part of a salvage regimen for individuals who have failed multiple other regimens.
  6. CCR5 inhibitors: Maraviroc. Before using this drug, a viral trophism assay should be checked to determine if the virus uses the CCR5 co-receptor to infect cells. If the virus uses the CXCR4 co-receptor, this drug will not be effective.
  7. Post-attachment inhibitors: Ibalizumab. Blocks CD4 receptors that HIV needs to enter cells with.

TABLE 10 What Antiretroviral Regimen to Choose for Initial Therapy

Preferred Regimens	Comments
Integrase inhibitor-based regimen Bictegravir/TAF/FTC Raltegravir + TDF/FTC or TAF/FTC Dolutegravir + TDF/FTC or TAF/FTC Dolutegravir/ABC/3TC	Use abacavir only in individuals who are HLA-B*5701 negative.
PI-based regimen Darunavir/r or Darunavir/c (once daily) + TDF/FTC or TAF/FTC	Use if there is a concern for drug resistance.
Preferred regimen for pregnant women ABC/3TC or TDF/FTC plus Raltegravir or Darunavir/r or Atazanavir/r	TDF should be avoided in renal impairment.
Alternative Regimens	**Comments**
INSTI-based regimens Elvitegravir/cobicistat/TDF/FTC Elvitegravir/cobicistat/TAF/FTC RAL + ABC/3TC	
NNRTI-based regimens (in alphabetical order) EFV/TDF/FTC or EFV + TAF/FTC EFV + ABC/3TC RPV/TDF/FTC or RPV/TAF/FTC RPV + ABC/3TC	EFV should not be used with caution in the first trimester of pregnancy or in women trying to conceive. NVP should not be used in patients with moderate to severe hepatic impairment (Child-Pugh B or C) Should not be used in women with pre-treatment CD4 >250 cells/mm^3 or men with CD4 >400 cells/mm^3
PI-based regimens (in alphabetical order) ATV/r or ATV/c + ABC/3TC ATV/r or ATV/c + TDF/FTC or TAF/FTC DRV/c or DRV/r + ABC/3TC	ABC should not be used in patients who test positive for HLA-B*5701 Use with caution in patients with high risk of cardiovascular disease or with pretreatment HIV RNA >100,000 copies/ml Once-daily LPV/r is not recommended in pregnant women.

3TC, Lamivudine; *ABC,* abacavir; *ATV,* atazanavir; *DRV,* darunavir; *EFV,* efavirenz; *FPV,* fosamprenavir; *FTC,* emtricitabine; *INSTI,* integrase strand transfer inhibitor; *LPV,* lopinavir; *MRV,* maraviroc; *NNRTI,* nonnucleoside reverse transcriptase inhibitor; *NRTI,* nucleos(t)ide reverse transcriptase inhibitor; *NVP,* nevirapine; *PI,* protease inhibitor; *r,* low dose ritonavir; *RAL,* raltegravir; *RNA,* ribonucleic acid; *RVP,* rilpivirine; *TAF,* tenofovir alafenamide; *TDF,* tenofovir disoproxil fumarate. The following combinations in the recommended list are available as fixed-dose combination formulations: ABC/3TC, EFV/TDF/FTC, LPV/r, TDF/FTC, RPV/TDF/FTC, and ZDV/3TC.

Modified from DHHS Panel on Antiretroviral Guidelines for Adults and Adolescents: Guidelines for the use of antiretroviral agents in adults and adolescents with HIV. Department of Health and Human Services 1-161, 2018. www.aidsinfo.nih.gov/ContentFiles/AdultandAdolescentGL.pdf.

- Adding a fourth drug to the three-drug regimen does not improve viral suppression or outcomes and is not recommended. Treatment interruptions based upon CD4 responses appear harmful in recent comparative studies versus standard continuous treatment protocols and should be avoided. Antiretroviral regimens for initial therapy are summarized in Table 10.
- Typical dosing regimen consists of two NRTIs and either a NNRTI, PI, or II. IIs are now the preferred third drug because of tolerability. Data support inclusion of lamivudine or emtricitabine as one of the two NRTIs.
- Individuals with drug resistant HIV may be on more complex and atypical regimens. Consultation with an HIV specialist is recommended.

Standard NRTIs include:

- Tenofovir disoproxil fumarate/emtricitabine 1 tablet once daily. Individuals with underlying renal dysfunction or requiring other nephrotoxic agents may be at increased risk of renal toxicity while taking tenofovir. TDF may also be associated with reductions in bone mineral density.
- Tenofovir alafenamide/emtricitabine 1 tablet once daily. TAF is a newer formulation of TDF with less nephrotoxicity and bone mineral density effects. Both TDF/FTC, and TAF/FTC are recommended components of the initial regimen (with a "backbone" medication). TDF should be avoided in patients with a creatinine clearance (CrCl) <60 ml/min. TAF should be avoided in patients with a CrCl <30 ml/min.
- Abacavir/lamivudine 1 tablet once daily. Abacavir may be associated with increased risk of myocardial infarction. Before using this drug, individuals should be checked for HLA-B*5701. Individuals with this allele are at higher risk of serious hypersensitivity reactions, and this drug should be avoided.
- Zidovudine/lamivudine 1 tablet twice daily. Once widely prescribed; now rarely used due to lower efficacy compared with tenofovir-emtricitabine; zidovudine is associated with lipoatrophy and anemia, as well as GI and CNS side effects.

Standard backbone regimens include:

- IIs (these are now considered first line):
  1. Bictegravir (50 mg once daily): Fixed-dose combination of bictegravir with the NRTIs TAF and FTC.
  2. Dolutegravir (50 mg once daily): Fixed-dose combination of dolutegravir and the NRTIs abacavir and lamivudine for once-daily treatment of HIV-1 infection. HLA-B*5701 should be checked first.
  3. Elvitegravir: Given with cobicistat (booster) and tenofovir/emtricitabine in a fixed-dose combination.
  4. Raltegravir (400 mg twice a day).
- NNRTIs:
  1. Efavirenz 600 mg daily: Should be used in caution in women in the first trimester or those who are contemplating pregnancy.
  2. Rilpivirine: Given with tenofovir and emtricitabine as part of a fixed-dose combination.
  3. Nevirapine 200 mg two times a day: Avoid with CD4 count >250 in men and >350 cells per cubic millimeter in women because of the risk of hepatitis. The newer agent rilpivirine had higher virologic failures and should be considered an alternative agent.
  4. Etravirine 200 mg two times a day: This drug is generally used in patients for whom other regimens have failed. Etravirine retains activity in many patients who have developed resistance against efavirenz and nevirapine.
- PIs (ritonavir boosted):
  1. Darunavir and ritonavir (800 mg and 100 mg a day): This is considered a preferred PI regimen within the U.S. Department of Health and Human Services (DHHS) guidelines with either tenofovir disoproxil fumarate or TAF and emtricitabine.
  2. Atazanavir and ritonavir (300 mg and 100 mg) 2 tablets a day: Lower pill burden, but use with caution with acid-reducing agents (can alter absorption).
  3. Lopinavir and ritonavir (200 mg/50 mg) 2 tablets twice a day (or 4 tablets once a day): Most likely to cause diarrhea and has the greatest negative effect on triglyceride levels.
  4. Fosamprenavir and ritonavir (700 mg and 100 mg) 2 tablets twice a day (or 4 tablets once a day): Cannot take fosamprenavir with sulfa allergy.
  5. Saquinavir and ritonavir: Saquinavir is no longer recommended for initial treatment of any patient and should be prescribed only in consultation with a specialist.
- All these drugs have their own unique, as well as class-specific, side effects and require careful follow-up to achieve optimal antiviral effects. Compliance with the drug regimen and tolerance of common side effects are critically important to maintain drug efficacy. Antiviral response should be monitored by baseline HIV viral load and CD4 count and repeat measurement at 2 and 4 weeks into treatment and then periodically (every 3-6 months) to ensure viral suppression.
- All patients should have genotypic resistance testing upon entry into medical care and before initiation of ART.
- In experienced patients, an antiretroviral regimen should be constructed based on past antiretroviral use and the results of genotypic or phenotypic testing.

- Patients with a CD4 count <200/mm^3 should be given preventive therapy for PJP (Table 11).
- Evaluation of chronic diarrhea in patients with HIV is described in the AIDS topic in Section I.
- Criteria for discontinuing and restarting opportunistic infection prophylaxis for adults and adolescents with HIV infection is described in Table 12.
- HIV infection in a pregnant woman poses special challenges and considerations. Appropriate and timely ART given to mother and newborn has been shown to dramatically reduce the risk of perinatal transmission of HIV. The goal of therapy is to achieve an undetectable viral load. For HIV-infected pregnant women who are already receiving ART: (1) Continue therapy if suppressing viral replication, but avoid use of efavirenz in the first trimester (substitution is recommended in the first trimester); (2) if viremia on therapy, genotypic testing is recommended. For HIV-infected pregnant women who have never received ART: (1) All women should start on ART as soon as possible. Most antiretrovirals are safe in pregnancy; however, efavirenz should be avoided because of possible teratogenicity (Class D), DDI and D4T should be avoided (potential of lactic acidosis), and some protease inhibitors may be dose-altered in pregnancy. Importantly, dolutegravir (DTG) should be avoided in the first trimester because of an increased risk for neural tube defects. Nevirapine should not be initiated in an antiretroviral-naive pregnant patient with CD4 counts >250 cells/mm^3 because of the risk of hepatotoxicity. (2) Women who do not need ART for their own health should also initiate three-drug therapy, but may do so at the end of the first trimester.

TABLE 11 Criteria for Discontinuing and Restarting Opportunistic Infection Prophylaxis for Adults and Adolescents with Human Immunodeficiency Virus Infection

Opportunistic Infection	Criteria for Discontinuing Primary Prophylaxis	Criteria for Restarting Primary Prophylaxis	Criteria for Discontinuing Secondary Prophylaxis/Chronic Maintenance Therapy	Criteria for Restarting Secondary Prophylaxis/ Chronic Maintenance Therapy
Pneumocystis pneumonia (PJP)	CD4$^+$ count >200 cells/mm^3 for >3 mo in response to ART	CD4$^+$ count <200 cells/mm^3	CD4$^+$ count increased from <200 cells/mm^3 to >200 cells/mm^3 for ≥3 mo in response to ART If PJP is diagnosed when CD4$^+$ count >200 cells/mm^3, prophylaxis should probably be continued for life regardless of CD4$^+$ count rise in response to ART.	CD4$^+$ count <200 cells/mm^3, or if PCP recurred at a CD4$^+$ count >200 cells/mm^3
Toxoplasma gondii encephalitis (TE)	CD4$^+$ count >200 cells/mm^3 for >3 mo in response to ART	CD4$^+$ count <100-200 cells/mm^3	Successfully completed initial therapy, remain asymptomatic of signs and symptoms of TE, and CD4$^+$ count >200 cells/mm^3 for >6 mo in response to ART	CD4$^+$ count <100 cells/mm^3
Microsporidiosis	Not applicable	Not applicable	No signs and symptoms of non-ocular microsporidiosis and CD4$^+$ count >200 cells/mm^3 for >6 mo in response to ART Patients with ocular microsporidiosis should be on therapy indefinitely regardless of CD4$^+$ count.	No recommendation
Disseminated *Mycobacterium avium* complex (MAC) disease	CD4$^+$ count >100 cells/mm^3 for ≥3 mo in response to ART	CD4$^+$ count <50 cells/mm^3	If fulfill the following criteria Completed ≥12 mo therapy, and No signs and symptoms of MAC, and Have sustained (≥6 mo) CD4$^+$ count >100 cells/mm^3 in response to ART	CD4$^+$ count <50 cells/mm^3
Bartonellosis	Not applicable	Not applicable	If fulfill the following criteria Received 3-4 mo of treatment CD4$^+$ count >200 cells/mm^3 for ≥6 mo Certain specialists would discontinue therapy only if *Bartonella* titers have also decreased by fourfold.	No recommendation
Mucosal candidiasis	Not applicable	Not applicable	If used, reasonable to discontinue when CD4$^+$ count >200 cells/mm^3	No recommendation
Cryptococcal meningitis	Not applicable	Not applicable	If fulfill the following criteria Completed course of initial therapy Remain asymptomatic of cryptococcosis CD4$^+$ count ≥200 cells/mm^3 for >6 mo in response to ART Certain specialists would perform a lumbar puncture to determine if cerebrospinal fluid is culture and antigen negative before stopping therapy.	CD4$^+$ count <100 cells/mm^3
Histoplasma capsulatum infection	If used, CD4$^+$ count >150 cells/mm^3 for 6 mo on ART	For patients at high risk for acquiring histoplasmosis, restart at CD4$^+$ count ≤150 cells/mm^3.	If fulfill the following criteria received itraconazole for ≥1 yr Negative blood cultures CD4$^+$ count >150 cells/mm^3 for ≥6 mo in response to ART Serum *Histoplasma* antigen <2 units	CD4$^+$ count ≤150 cells/mm^3

Continued

TABLE 11 Criteria for Discontinuing and Restarting Opportunistic Infection Prophylaxis for Adults and Adolescents with Human Immunodeficiency Virus Infection—cont'd

Opportunistic Infection	Criteria for Discontinuing Primary Prophylaxis	Criteria for Restarting Primary Prophylaxis	Criteria for Discontinuing Secondary Prophylaxis/Chronic Maintenance Therapy	Criteria for Restarting Secondary Prophylaxis/ Chronic Maintenance Therapy
Coccidioidomycosis	If used, $CD4^+$ count ≥250 cells/mm^3 for ≥6 mo	If used, restart at $CD4^+$ count <250 cells/mm^3	**Only for patients with focal coccidioidal pneumonia:** Clinically responded to ≥12 mo of antifungal therapy $CD4^+$ count >250 cells/mm^3 Receiving ART Suppressive therapy should be continued indefinitely, even with increase in $CD4^+$ count on ART for patients with diffuse pulmonary, disseminated, or meningeal diseases.	No recommendation
Cytomegalovirus retinitis	Not applicable	Not applicable	$CD4^+$ count >100 cells/mm^3 for >3-6 mo in response to ART. Therapy should be discontinued only after consultation with an ophthalmologist, taking into account magnitude and duration of $CD4^+$ count increase, anatomic location of the lesions, vision in the contralateral eye, and the feasibility of regular ophthalmologic monitoring. Routine (every 3 mo) ophthalmologic follow-up is recommended for early detection of relapse or immune restoration uveitis.	No recommendation
Isospora belli infection	Not applicable	Not applicable	Sustained increase in $CD4^+$ count to >200 cells/mm^3 for >6 mo in response to ART and without evidence of *I. belli* infection	No recommendation

ART, Antiretroviral therapy.

Modified from Centers for Disease Control and Prevention: Guidelines for prevention and treatment of opportunistic infections in HIV-infected adults and adolescents. Recommendations from CDC, the National Institutes of Health, and the HIV Medicine Association of the Infectious Disease Society of America, *MMWR* 58(RR-4), 2009.

TABLE 12 Prophylaxis to Prevent First Episode of HIV-related Opportunistic Disease

Pathogen	Indication	First Choice	Alternative
Pneumocystis jiroveci pneumonia (PJP, previously referred to as *Pneumocystis carinii,* PCP)	$CD4^+$ count <200 cells/mm^3 or oropharyngeal candidiasis$CD4^+$ <14% or history of AIDS-defining illness $CD4^+$ count >200 but <250 cells/mm^3 if monitoring $CD4^+$ count every 1-3 mo is not possible	Trimethoprim-sulfamethoxazole (TMP-SMX) double-strength PO daily; *or* single-strength daily	TMP-SMX 1 double-strength PO 3 times weekly; *or* Dapsone 100 mg PO daily or 50 mg PO bid; *or* Aerosolized pentamidine 300 mg via Respirgard II nebulizer every month; *or* Atovaquone 1500 mg PO daily
Toxoplasma gondii encephalitis	*Toxoplasma* IgG–positive patients with $CD4^+$ count <100 cells/mm^3Seronegative patients receiving PCP prophylaxis not active against toxoplasmosis should have *Toxoplasma* serology retested if $CD4^+$ count declines to <100 cells/mm^3. Prophylaxis should be initiated if seroconversion occurred.	TMP-SMX, 1 double-strength PO daily	TMP-SMX 1 double-strength PO 3 times weekly; *or* TMP-SMX 1 single-strength PO daily; *or* Dapsone 50 mg PO daily + pyrimethamine 50 mg PO weekly + leucovorin 25 mg PO weekly; *or* Dapsone 200 mg PO weekly + pyrimethamine 75 mg PO weekly + leucovorin 25 mg PO weekly
Mycobacterium tuberculosis infection (TB) (treatment of latent TB infection or LTBI)	(1) Diagnostic test for LTBI, no evidence of active TB, and no prior history of treatment for active or latent TB (2) Diagnostic test for LTBI, but close contact with a person with infectious pulmonary TB and no evidence of active TB (3) A history of untreated or inadequately treated healed TB (i.e., old fibrotic lesions) regardless of diagnostic tests for LTBI and no evidence of active TB	Isoniazid (INH) 300 mg PO daily or 900 mg PO twice weekly for 9 mo—both plus pyridoxine 25 mg PO daily; *or* For persons exposed to drug-resistant TB, selection of drugs after consultation with public health authorities	Rifampin (RIF) 600 mg PO daily × 4 mo; or Rifabutin (dosage depends on ART regimen). Be careful of drug interactions with these medications (PIs and NNRTIs) Isoniazid (15 mg/kg rounded up to the nearest 50 or 100 mg; 900 mg maximum) and rifapentine (10-14.0 kg 300 mg; 14.1-25.0 kg 450 mg; 25.1-32.0 kg 600 mg; 32.1-49.9 kg 750 mg; ≥50.0 kg 900 mg maximum) once weekly for a total of 3 mo

TABLE 12 Prophylaxis to Prevent First Episode of HIV-related Opportunistic Disease—cont'd

Pathogen	Indication	First Choice	Alternative
Disseminated *Mycobacterium avium* complex (MAC) disease	$CD4^+$ count <50 cells/mm^3—after ruling out active MAC infection	Azithromycin 1200 mg PO once weekly; *or* Clarithromycin 500 mg PO bid; *or* Azithromycin 600 mg PO twice weekly	RFB 300 mg PO daily (dosage adjustment based on drug-drug interactions with antiretroviral therapy); rule out active TB before starting RFB
Streptococcus pneumoniae infection	$CD4^+$ count >200 cells/mm^3 and no receipt of pneumococcal vaccine in the past 5 yr. $CD4^+$ count <200 cells/mm^3—vaccination can be offered In patients who received polysaccharide pneumococcal vaccination (PPV) when $CD4^+$ count <200 cells/mm^3 but has increased to >200 cells/mm^3 in response to antiretroviral therapy	A single dose of PCV13 followed by a single dose of PPSV23 at least 8 wk later. A second dose of PPSV23 should be given 5 yr after the initial PPSV23 dose.	
Influenza A and B virus infection	All HIV-infected patients	Inactivated influenza vaccine 0.5 ml IM annually	
Histoplasma capsulatum infection	$CD4^+$ count ≤150 cells/mm^3 and at high risk because of occupational exposure or live in a community with a hyperendemic rate of histoplasmosis (>10 cases/100 patient-yr)	Itraconazole 200 mg PO daily	
Coccidioidomycosis	Positive IgM or IgG serologic test result in a patient from a disease-endemic area; and $CD4^+$ count <250 cells/mm^3	Fluconazole 400 mg PO daily itraconazole 200 mg PO bid	
Varicella-zoster virus (VZV) infection	*Pre-exposure prevention:* Patients with $CD4^+$ count ≥200 cells/mm^3 who have not been vaccinated, have no history of varicella or herpes zoster, or who are seronegative for VZV NOTE: Routine VZV serologic testing in HIV-infected adults is not recommended. *Postexposure—close contact with a person who has active varicella or herpes zoster* For susceptible patients (those who have no history of vaccination or of either condition, or are known to be VZV seronegative)	*Pre-exposure prevention:* Primary varicella vaccination (Varivax), 2 doses (0.5 ml SC) administered 3 mo apart. If vaccination results in disease because of vaccine virus, treatment with acyclovir is recommended. *Postexposure therapy:* Varicella-zoster immune globulin (VariZIG) 125 IU per 10 kg (maximum of 625 IU) IM, administered within 96 hr after exposure to a person with active varicella or herpes zoster NOTE: As of June 2007, VariZIG can be obtained only under a treatment IND (1-800-843-7477, FFF Enterprises).	VZV-susceptible household contacts of susceptible HIV-infected persons should be vaccinated to prevent potential transmission of VZV to their HIV-infected contacts. Alternative postexposure therapy: Postexposure varicella vaccine (Varivax) 0.5 ml SC × 2 doses, 3 mo apart if $CD4^+$ count >200 cells/mm^3; *or* Preemptive acyclovir 800 mg PO 3×/day for 5 days These two alternatives have not been studied in the HIV population.
Human papillomavirus (HPV) infection	Women aged 11-26 yr. Men aged 11-26 yr	HPV quadrivalent vaccine 0.5 ml IM mo 0, 2, and 6	
Hepatitis A virus (HAV) infection	HAV-susceptible patients with chronic liver disease or who are injection-drug users, or men who have sex with men. Certain specialists might delay vaccination until $CD4^+$ count >200 cells/mm^3.	Hepatitis A vaccine 1 ml IM × 2 doses—at 0 and 6-12 mo IgG antibody response should be assessed 1 mo after vaccination; nonresponders should be revaccinated	
Hepatitis B virus (HBV) infection	All HIV patients without evidence of prior exposure to HBV should be vaccinated with HBV vaccine, including patients with $CD4^+$ count <200 cells/mm^3. *Patients with isolated anti-HBc:* Consider screening for HBV DNA before vaccination to rule out occult chronic HBV infection	Hepatitis B vaccine IM (Engerix-B 20 μg/ml or Recombivax HB 10 μg/ml) at 0, 1, and 6 mo Anti-HBs should be obtained 1 mo after completion of the vaccine series.	Some experts recommend vaccinating with 40-μg doses of either vaccine.
	Vaccine nonresponders: Defined as anti-HBs <10 IU/ml 1 mo after a vaccination series For patients with low $CD4^+$ count at the time of first vaccination series, certain specialists might delay revaccination until after a sustained increase in $CD4^+$ count with antiretroviral therapy.	Revaccinate with a second vaccine series.	Some experts recommend revaccinating with 40-μg doses of either vaccine.

ART, Antiretroviral therapy; *HB,* hepatitis B; *IG,* immunoglobulin; *IM,* intramuscular; *IND,* investigational new drug; *NNRTI,* nonnucleoside analog reverse transcriptase inhibitor; *PI,* protease inhibitors; *PO,* by mouth; *RFB,* rifabutin.

Modified from Centers for Disease Control and Prevention: Guidelines for prevention and treatment of opportunistic infections in HIV-infected adults and adolescents: recommendations from CDC, the National Institutes of Health, and the HIV Medicine Association of the Infectious Disease Society of America, *MMWR* 58(RR-4), 2009.

- Preferred ART medications during pregnancy include:
  1. NRTIs: TDF/FTC, TDF/3TC, or ABC/3TC
  2. INSTI: Raltegravir; dolutegravir can be used after the first trimester; limited data with bictegravir
  3. PIs: ATV/r or DRV/r
- ART should continue through the baby's birth. Zidovudine should also be given intravenously to the woman at the time of labor if the woman has an HIV RNA >1000 copies/ml or there is a concern for poor adherence, regardless of whether it is an existing component of her three-drug regimen. In women with viral loads persistently >1000 copies/ml despite appropriate ART, cesarean section may further lower risk of transmission. For women with HIV RNA <1000 copies/ml zidovudine (AZT) should also be given to the newborn for the first 6 weeks of life. If HIV RNA levels are >1000 copies/ml, infants should receive combination ART, which may include zidovudine, lamivudine and nevirapine for 6 weeks. Mothers should completely avoid nursing.

DISPOSITION

- Ongoing care consisting of frequent medical evaluations and monitoring of CD4 counts and HIV viral loads.
- Long-term care focused on providing up-to-date ART and prophylaxis of PJP and other opportunistic infections, as well as early detection of complications.
- Ongoing assessment for cardiovascular risk and other primary prevention interventions.
- Screening for hepatitis A, B, and C. Treatment when indicated. Drugs such as TDF and lamivudine have activity against both HIV and hepatitis B and may be used in patients with co-infection.
- Vaccinations including hepatitis A and B (when susceptible), pneumococcus (PCV13 and PPSV23), tetanus/diphtheria/pertussis, meningococcal, and influenza. Box 1 summarizes vaccinations in HIV-positive adults.
- Yearly screening for other sexually transmitted infections (chlamydia, gonorrhea, and syphilis). This includes trichomonas in women and extragenital testing for chlamydia and gonorrhea (i.e., pharyngeal and rectal) in MSM.

BOX 1 Vaccination in HIV-Positive Adults

Generally Avoid
- BCG
- Oral polio
- Oral typhoid

Avoid if CD4+ Cells <200
- Yellow fever
- Measles
- Varicella-zoster virus (VZV)

Give Routinely
- Tetanus/diphtheria (or Tdap)
- Hepatitis A/B
- *Streptococcus pneumoniae*
- Hib
- Meningococcal
- Influenza, yearly

Give if Indicated for Travel
- Typhoid Vi
- Meningococcal
- Polio, IPV
- Rabies
- Japanese encephalitis
- Tick-borne encephalitis

From Auerbach P: *Wilderness medicine, expert consult,* premium edition—enhanced online features and print, Philadelphia, 2012, WB Saunders.

- Consideration of AIDS (lymphomas, HPV) and non-AIDS related (screening for general population, age-specific cancers).

REFERRAL

To a physician knowledgeable and experienced in the management of HIV infection and its complications.

PREVENTION

- TDF/FTC may be used as pre-exposure prophylaxis (PrEP). Individuals who are HIV negative may take TDF/FTC once a day to prevent HIV infection. PrEP has been demonstrated to be effective in MSM, heterosexuals, and injection drug users. Individuals on PrEP should be monitored every three months for renal dysfunction, HIV status, and adherence.
- Post-exposure prophylaxis (PEP) is an effective prevention intervention for individuals exposed to HIV infection, either occupationally or through a sexual exposure. PEP should be taken within 72 hours of an exposure and continued for 28 days. Baseline HIV status, renal function, hepatitis B/C, and liver function should be assessed. The recommended first-line regimen is tenofovir-emtricitabine 300/200 mg once daily plus raltegravir 400 mg orally twice daily or Dolutegravir 50mg once daily. Dolutegravir should be avoided in women of childbearing potential or who are pregnant.

PEARLS & CONSIDERATIONS

COMMENTS

- ART should be initiated in all HIV-infected individuals regardless of CD4 cell counts.
- ART in combination with avoidance of breastfeeding and elective cesarean section in women with viremia reduces risk for mother-to-child transmission.

A

1. Screen with an HIV-1/2/p24 antibody/antigen assay. If negative, chances of an established HIV-1 or HIV-2 infection are low.
2. Test screen positive samples with immunoassay that differentiates between HIV-1 and HIV-2.
3. Specimens with a reactive screen and negative or indeterminate for HIV-1/HIV-2 differentiation need to be confirmed by HIV-1 NAAT.
    1. A reactive HIV-1 NAAT result and a nonreactive HIC-1/HIV-2 antibody differentiation immunoassay are consistent with laboratory evidence of acute HIV-1 infection.
    2. A reactive HIV-1 NAAT result and indeterminate HIV-1/HIV-2 antibody differentiation immunoassay indicate a false positive on the initial screen immunoassay.
    3. A negative HIV-1 NAAT results and nonreactive or indeterminate HIV-1?HIV-2 antibody differentiation immunoassay result are consistent with a false positive result on the initial screening immunoassay.
4. Laboratories should use this same testing algorithm, beginning with the antigen/antibody combination screen immunoassay, with serum or plasma specimens submitted for testing after a reactive result from any rapid HIV test.
5. No further testing is required for specimens that are nonreactive on the initial screening immunoassay.
6. Inconsistent or conflicting results should be investigated with follow-up testing on a newly collected specimen.

Assay	Comments
Prognosis/Monitoring Treatment	

HIV viral load
  	
	• The same method should be used for monitoring individual patients to minimize technical variation in HIV blood levels.
	• HIV viral load testing is used to
	  • Diagnose acute retroviral syndrome before seroconversion develops.
	  • Assess prognosis and progression of HIV disease.
	  • Guide antiretroviral therapy.
	  • Define a baseline level so that response to therapy can be measured.
	  • Monitor response to therapy.
	• Greater than 0.5 log (3-fold) change in blood HIV load is considered clinically significant.

Genotypic HIV assays  Resistance-associated reverse transcriptase (RT) mutation K103N Resistance to nevirapine and efavirenz	• Genotypic assays are helpful in antiretroviral-naive patients for initial assessment of treatment options. Genotyping is also useful for patients who develop virologic failure with rising HIV viral load during highly active antiretroviral therapy, and need guidance for treatment modification. • Genotyping detects changes in the nucleic acid sequence of the relevant HIV1 gene and identifies drug resistance by detecting mutations in the HIV1 genome that lead to specific amino acid substitutions in the HIV1 RT or protease enzymes.
Phenotypic assays  	• Phenotypic assays amplify RT and protease genes from the patient's HIV predominant quasi-species virus RNA or proviral DNA. These amplicons are then inserted into a laboratory virus that lacks the genes, creating a hybrid virus. The hybrid virus is then propagated in cell culture, and its ability to propagate in the presence of varying concentrations of the anti-HIV agent is measured. Results are expressed as concentrations of drug required to inhibit 50% of growth (IC50) compared with a wild-type control strain.
Virtual phenotypes	• The patient's HIV genotype is compared with a database containing many known HIV drug-resistant and susceptible genotypes to predict the patient's response to therapy.

B

Assay	Comments
Immune Status	

CD4 cell counts
(% CD4 and absolute number)
  	
	• CD4 cell count and CD4/CD8 ratio are used to
	  • Stage HIV disease.
	  • Help establish the risk of specific HIV-associated infectious or neoplastic complications.
	  • Determine the need for prophylaxis against opportunistic infections.
	  • Determine the need for and response to antiretroviral therapy.

C

FIG. E2, cont'd.

BASIC INFORMATION

DEFINITION

Huntington disease (HD) is a trinucleotide repeat autosomal dominant neurodegenerative disorder characterized by involuntary movements, psychiatric disturbance, and cognitive decline. The disease exhibits the genetic phenomenon of anticipation, such that subsequent generations have longer repeats and a younger age of onset (Table E1).

SYNONYMS

Huntington chorea
HD

ICD-10CM CODE
G10 Huntington disease

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: Late 30s and 40s, with onsets from ages 2 to 70 yr.

Age of onset, but not necessarily disease severity, correlates with CAG repeat numbers.
PREVALENCE (IN U.S.): 4.1 to 8.4 cases/100,000 persons. Most common neurodegenerative cause of generalized chorea.
PREDOMINANT SEX: Female = male
PREDOMINANT AGE: Adulthood
GENETICS: Autosomal dominant

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Chorea: Irregular, rapid, flowing, nonstereotyped involuntary movements (Fig. E1). When there is a writhing quality, it is referred to as choreoathetosis. Chorea is present early on and tends to decrease in end stages of disease.
- Dancelike, lurching gait (Fig. E2), often caused by chorea.
- Westphal variant: Cognitive dysfunction, bradykinesia, and rigidity. This variant is more commonly seen in juvenile-onset Huntington.
- Oculomotor abnormalities are common early on and include increased latency of response and insuppressible eye blinking.
- Psychiatric disorders (can be present early on): Depression is commonly seen, as well as obsessive-compulsive behaviors and aggression associated with impaired impulse control.

ETIOLOGY

- Trinucleotide repeat disorder; repeat of CAG, which codes for glutamine
- The responsible gene is the *huntingtin* gene (*HTT*), located on chromosome 4. Its function is not known.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Drug-induced chorea: Dopamine, stimulants, anticonvulsants, antidepressants, and oral contraceptives have all been known to cause chorea.
- Sydenham chorea: Decreased incidence with decline of rheumatic fever.
- Benign hereditary chorea: Autosomal dominant with onset in childhood; nonprogressive and without associated dementia or behavioral problems.
- Senile chorea: Possibly vascular in origin.
- Wilson disease: Autosomal recessive; tremor, dysarthria, and dystonia are more common presentations than chorea. A total of 95% of patients with neurologic manifestations will have Kayser-Fleischer rings.
- Postinfectious.
- Systemic lupus erythematosus: Can be the presenting feature of lupus (rare).
- Chorea gravidarum: Presents during first 4 to 5 mo of pregnancy and resolves after delivery.
- Paraneoplastic: Seen most commonly in small-cell lung cancer and lymphoma.
- *C9orf72* mutation: Originally described as a leading cause of frontotemporal dementia-amyotrophic lateral sclerosis; it is also the most common phenocopy of HD in people of European origin.
- Huntington disease–like syndrome 2: This is the most common Huntington disease–like syndrome caused by GTC/CAG triplet expansions in the JPH3 gene encoding junctophilin-3 and found exclusively in people of African descent.

WORKUP

Onset of symptoms in an individual with an established family history requires no additional investigation.

LABORATORY TESTS

- Genetic testing for CAG repeat numbers. Genetic testing should be ordered only with appropriate pretesting and posttesting genetic counseling.
- If no CAG repeat is in the *huntingtin* gene, other genetic mutations may be producing a phenocopy of Huntington disease. Consider additional genetic tests, such as spinocerebellar ataxia type 17, the *C9orf2* hexanucleotide repeat (in people of European descent), the GTC/CAG triplet expansions in the JPH3 gene encoding junctophilin-3 (in people of African descent).
- Also obtain complete blood count with smear, erythrocyte sedimentation rate, electrolytes, serum ceruloplasmin, 24-h urinary copper excretion, thyroid panel, antinuclear antibody, liver function tests, HIV, and ASO titer. Consider paraneoplastic markers.

IMAGING STUDIES

CT scan or MRI scan (Fig. E3) will show atrophy, most notably in the caudate and putamen. In some cases, the striatal atrophy causes a characteristic appearance of the lateral ventricles on imaging termed "boxcar ventricles." The cortex is involved to a lesser extent. A normal scan does not exclude the diagnosis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Supportive counseling
- Physical and occupational therapy
- Home health care
- Genetic counseling

CHRONIC Rx

- Chorea does not need to be treated unless it is disabling.
- Tetrabenazine and deutetrabenazine are both approved by the FDA for the symptomatic treatment of chorea seen in Huntington disease. They are both a reversible inhibitor of the vesicle monoamine transporter type 2 (VMAT-2), inhibiting primarily dopamine and to a lesser degree serotonin and norepinephrine. Side effects include parkinsonism and severe depression. Deutetrabenazine appears to have a lower incidence of neuropsychiatric adverse effects than tetrabenazine. Both drugs are expensive and have no effect on disease progression.
- Neuroleptics, typical or atypical, can be used for symptomatic management of neuropsychiatric issues and chorea at low doses (e.g., haloperidol 1 to 10 mg/day).
- Amantadine (up to 300 to 400 mg divided tid).
- Depression with suicidal ideation is common; may improve with tricyclic antidepressants or SSRIs.
- Recent trials[1] involving intrathecal administration of IONIS-HTT_{Rx}, an antisense oligonucleotide designed to inhibit HTT messenger RNA and thereby reduce concentration of mutant *huntingtin* in patients with early Huntington disease, have shown

TABLE E1 CAG Repeats and Disease Risk

CAG Repeat #	Allele Classification	Disease Risk	Risk to Offspring
≤26	Normal	No symptoms	None
27-35	Intermediate	No symptoms	Low
36-39	Disease	At risk for HD	Moderate
≥40	Disease	HD imminent	High

HD, Huntington disease.

[1]Tabrizi SJ et al: Targeting huntingtin expression in patients with Huntington's disease, *N Engl J Med* 380(24):2307-2316, 2019.

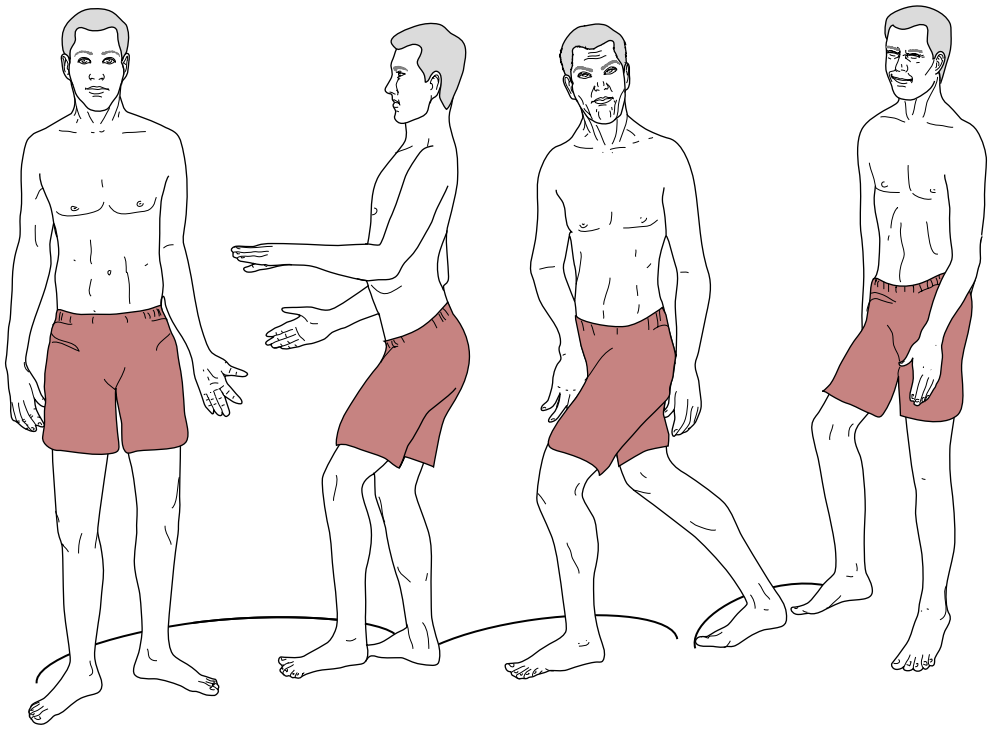

FIG. E1 The signature of Huntington disease is a jerky gait that results from intermittent, unexpected trunk and pelvic motions, spontaneous knee flexion and extension, lateral swaying, variable cadence, and unequal stride length. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

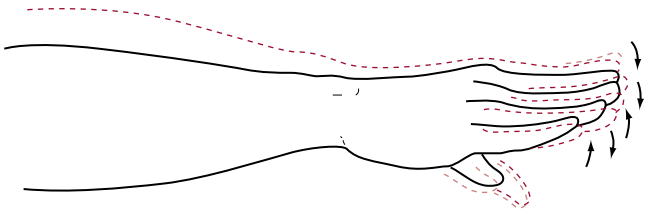

FIG. E2 With their arms and hands extended, Huntington disease patients fidget with their fingers and wrists. Neurologists label these movements "piano playing." (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

dose-dependent reductions in concentration of mutant *huntingtin* without serious side effects.

DISPOSITION

Relentless course of variable duration leading to progressive disability and death

REFERRAL

- Should refer to psychiatry and neurology for treatment of mood disorders and movement disorders
- Genetic counseling

PEARLS & CONSIDERATIONS

- Suicide rate is fivefold that of the general population.
- Generational transmission is often associated with the phenomenon of "anticipation," with disease starting at an earlier age in a child because of increased repeat length compared with that of the parent.
- Childhood-onset HD presents with parkinsonism rather than with chorea.
- The number of repeats does correlate with age of onset but does not clearly correlate with disease severity. Interpretation of number of repeats is still difficult at this time; therefore, it is debatable whether to disclose this information to patients.

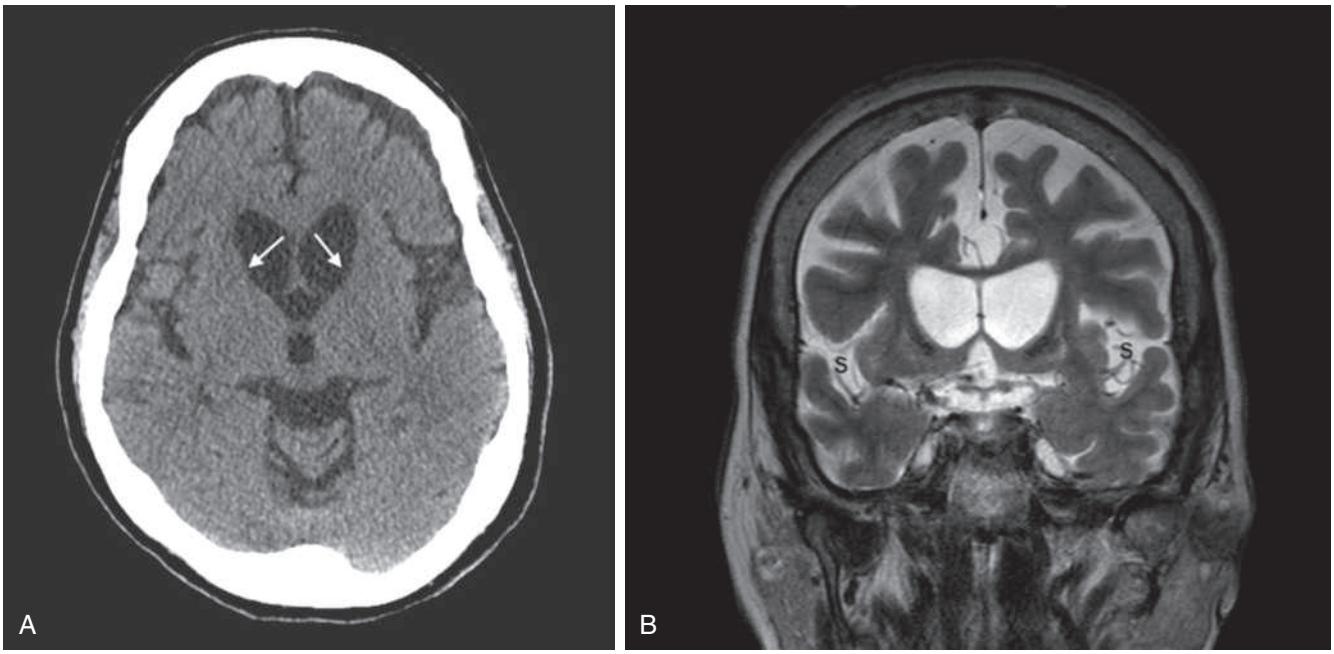

FIG. E3 A, This computed tomography scan shows the characteristic abnormality of Huntington disease: The anterior horns of the lateral ventricles are convex (bowed outward) because of atrophy of the caudate nuclei *(arrows).* The convex shape of the ventricles in Huntington disease contrasts with the concave shape seen in normal individuals and in those with cerebral atrophy and hydrocephalus ex vacuo. In addition to the caudate atrophy, Huntington disease, like many other neurodegenerative illnesses, is associated with cortical atrophy with widened sulci and enlarged ventricles. **B,** This *coronal* view of the magnetic resonance image of the same patient also shows the convex expansion of the lateral ventricles, large sulci, and widened Sylvian fissures *(S).* (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

BASIC INFORMATION

DEFINITION

A hydrocele is a fluid collection in a serous scrotal space, usually between the layers of the tunica vaginalis (Fig. E1). A hydrocele that fills with fluid from the peritoneum is termed *communicating*. This is distinguished from a *noncommunicating* hydrocele by history of variation in size throughout the day and palpation of a thickened cord above the testicle on the affected side. A communicating hydrocele is a small inguinal hernia in which fluid, but not peritoneal structures, traverses the processus vaginalis. In noncommunicating hydrocele, the processus vaginalis was obliterated during development. An abdominoscrotal hydrocele is a rare variant of a hydrocele in which there is a large, tense hydrocele that extends into the lower abdominal cavity.

ICD-10CM CODES

N43.3	Hydrocele, unspecified
N43	Hydrocele and spermatocele
N43.0	Encysted hydrocele
N43.1	Infected hydrocele
N43.2	Other hydrocele
P83.5	Congenital hydrocele

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Symptoms:

- Scrotal enlargement (Fig. E2)
- Scrotal heaviness or discomfort radiating to the inguinal area
- Back pain

Physical findings:

- Most hydroceles are smooth and nontender. Scrotal distention may make it difficult to palpate the testis, but it is important to palpate the testis because some young men develop a hydrocele in association with a testis tumor.
- Transillumination of the scrotum confirms the fluid-filled nature of the mass (Fig. E3).

ETIOLOGY

Hydroceles may occur as a congenital abnormality in which the processus vaginalis fails to close. In this case an inguinal hernia is virtually always associated with the malformation. Congenital hydroceles are most common in infants (1% to 2% of neonates have hydroceles) and children. In adults, hydroceles are more frequently caused by infection, tumor, or trauma. Infection of the epididymis often results in the development of a secondary hydrocele. Tropical infections such as filariasis may produce hydroceles.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Spermatocele
- Inguinoscrotal hernia
- Testicular tumor
- Varicocele
- Epididymitis

IMAGING STUDIES

Scrotal ultrasound is useful to rule out a testicular tumor as the cause of the hydrocele (Fig. E4). The acute development of a hydrocele might be associated with the onset of epididymitis, testicular tumor, trauma, and torsion of a testicular appendage. An ultrasound of the scrotum may provide important diagnostic information.

TREATMENT

- No treatment if asymptomatic and testis is believed to be normal. Most congenital hydroceles resolve by 12 mo of age following reabsorption of the hydrocele fluid.
- Surgical repair should be considered if the hydrocele is tense and large. Communicating hydroceles should be repaired in the same manner as an indirect hernia. The indications for repair of a noncommunicating hydrocele include failure to resolve and increase in size to one that is large and tense.
- Surgical correction is similar to a herniorrhaphy: An inguinal incision is made, the spermatic cord is identified, the hydrocele fluid is drained, and a high ligation of the processus vaginalis is performed.

PEARLS & CONSIDERATIONS

- The long-term risk of a communicating hydrocele is the development of an inguinal hernia.
- An inguinal hernia/hydrocele is likely if compression of the fluid-filled mass completely reduces the hydrocele.

BASIC INFORMATION

DEFINITION

Normal pressure hydrocephalus (NPH) is a syndrome of symptomatic hydrocephalus in the setting of normal cerebrospinal fluid (CSF) pressure. The classic clinical triad of NPH includes gait disturbance, cognitive decline, and incontinence.

SYNONYMS

Normal pressure hydrocephalus
NPH
Occult hydrocephalus
Extraventricular obstructive hydrocephalus
Chronic hydrocephalus

ICD-10CM CODES
G91.2 Normal pressure hydrocephalus
G91.8 Other hydrocephalus

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The exact incidence is not known. In one study the incidence was found to be 5.5 per 100,000, but it may account for up to 5% of dementia in the U.S. Hospital discharge data suggest approximately 11,500 new cases diagnosed annually (may be overestimated). The prevalence of NPH may be as high as 14% among extended care facility patients.
PREDOMINANT SEX: Males = females
PREDOMINANT AGE: NPH is more common with increasing age. In one study of 1238 patients who had undergone a head CT and neuropsychiatric evaluation, 0.2% of patients between 70 and 79 had probable NPH, and 5.9% of those 80 yr old and older had probable NPH.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Gait difficulty: A "magnetic" gait in which patients have difficulty initiating ambulation, and the gait may be broad-based and shuffling, with the appearance that the feet are stuck to the floor.
- Cognitive decline: Mental slowing, forgetfulness, and inattention, typically without agnosia, aphasia, or other cortical disturbances.
- Incontinence: Initially may have urinary urgency; incontinence later develops. Fecal incontinence also occasionally occurs. In one prospective study of 55 consecutive patients with idiopathic NPH, nocturia was the most common symptom, urge incontinence was the most bothersome, and 100% had detrusor overactivity on urodynamic studies.
- *Gegenhalten* (paratonia or involuntary resistance with passive movement) or other frontal lobe signs may be seen.

ETIOLOGY

- Approximately 50% of cases are idiopathic; the remaining cases have a variety of causes, including prior subarachnoid hemorrhage, meningitis, head trauma, or intracranial surgery.
- Symptoms are presumed to result from stretching of sacral motor and limbic fibers that lie near the ventricles as dilation occurs.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Alzheimer disease with extrapyramidal features
- Cognitive impairment in the setting of Parkinson disease or parkinsonism-plus syndromes
- Dementia with Lewy bodies
- Frontotemporal dementia
- Cervical spondylosis with cord compromise in the setting of degenerative dementia
- Multi-infarct dementia
- HIV-associated dementia
- Table 1 differentiates MRI findings between hydrocephalus and atrophy

WORKUP

- Large-volume lumbar puncture:
  1. Time to walk a prespecified distance (usually 25 feet) is measured, followed by removal of 40 to 50 ml of CSF.
  2. Retest of timed walking is done later (sometimes at 1 and 4 hr). Patients who have significant improvement in gait are more likely to be shunt-responsive; those with mild or negative response can have variable outcomes.
  3. Opening and closing pressure are measured; if pressure is elevated, alternative causes must be considered. Higher *normal* pressure may predict a good outcome from CSF shunting (normal CSF pressure: 8 to 15 mm Hg or 10 to 18 cm H_2O).
- Measurement of CSF outflow resistance by an infusion test or CSF pressure monitoring is sometimes used to help predict surgical outcome. External lumbar drainage (ELD) is being used more commonly.

LABORATORY TESTS

- CSF should be sent for routine fluid analysis to exclude other pathologies.
- CSF biomarkers may be useful in excluding Alzheimer disease (e.g., Tau/A-beta 42).

IMAGING STUDIES

- CT scan or MRI (Fig. 1) can be used to document ventriculomegaly. The distinguishing feature of NPH is ventricular enlargement out of proportion to sulcal atrophy (Fig. E2), and typically the frontal horn ratio (Evans ratio) exceeds 0.40. An algorithm for evaluation of patients with enlarged ventricles is described in Fig. 3.
- MRI has advantages over CT, including better ability to visualize structures in the posterior fossa, visualize transependymal CSF flow (seen as periventricular T2 FLAIR hyperintensity), and document extent of white matter lesions. On MRI a flow void in the aqueduct and third ventricle ("jet sign"), thinning and elevation of the corpus callosum on sagittal images, rounding of the frontal horns, and a narrow CSF space at the high convexity/midline areas relative to Sylvian fissure size may be seen. MRI time-resolved 2D phase contrast imaging with velocity encoding can also be used to visualize CSF flow.
- Isotope cisternography and dynamic MRI studies have not been shown to be superior in predicting shunt outcome.

TREATMENT

There is no evidence that NPH can be effectively treated with medications. CSF diversion via a ventriculoperitoneal shunt is a definitive treatment.

NONPHARMACOLOGIC THERAPY

Response to ventriculoperitoneal shunting is variable. Some patients (variable depending on series reported) show significant improvement from shunting; however, effectiveness of shunting has never been demonstrated in a randomized controlled trial. Gait is most likely to improve.

TABLE 1 Differentiation between Hydrocephalus and Atrophy

	Hydrocephalus	Atrophy
Temporal horns	Enlarged	Normal (except in Alzheimer disease)
Third ventricle	Convex ▸ distended anterior recess	Concave ▸ normal anterior recess
Fourth ventricle	Normal or enlarged	Normal
Transependymal CSF migration	Presents acutely	Absent
Sulci	Flattened	Enlarged out of proportion to age

From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.

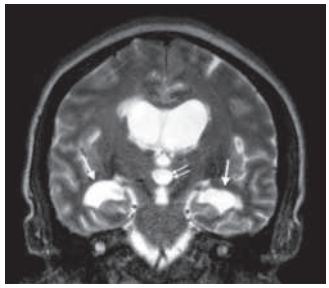

FIG. 1 This MRI study shows a coronal view of the brain of a patient with NPH. It demonstrates the classic findings: Dilation of the lateral ventricles, their temporal horns (*large arrows*), and the third ventricle (*pair of arrows*), and absence of cerebral atrophy. (From Kaufman DM et al: *Kaufman's clinical neurology for psychiatrists,* ed 8, Philadelphia, 2017, Elsevier.)

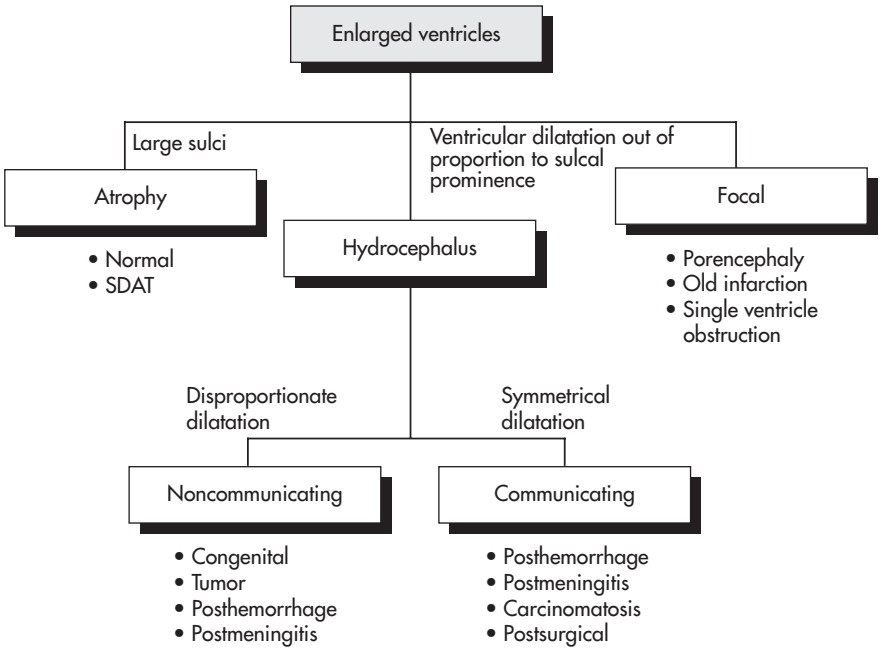

FIG. 3 Radiographic differential diagnosis of enlarged ventricles. *SDAT,* Senile dementia of the Alzheimer type. (From Weissleder R et al: *Primer of diagnostic imaging,* ed 5, St Louis, 2011, Mosby.)

Factors that may predict positive outcome with surgery:
- NPH caused by prior trauma, subarachnoid hemorrhage, or meningitis
- History of mild impairment in cognition <2 yr duration
- Onset of gait abnormality before cognitive decline
- Imaging demonstrates hydrocephalus without sulcal enlargement, including normal-size sylvian fissures and cortical sulci, and absent or mild white matter lesions
- Transependymal CSF flow visualized on MRI
- Large-volume tap or ELD produces dramatic but temporary relief of symptoms
- High *normal* opening pressure

Factors that may predict negative outcome with surgery:
- Extensive white matter lesions or diffuse cerebral atrophy on MRI
- Moderate to severe cognitive impairment
- Onset of cognitive impairment before gait disorder
- History of alcohol abuse

ACUTE GENERAL Rx

Shunting in selected patients

DISPOSITION

Symptoms of NPH may progress over time. Prompt diagnosis may improve chances for treatment success.

REFERRAL

To neurologist for initial evaluation, including lumbar puncture, followed by neurosurgeon for shunting in appropriate patients

PEARLS & CONSIDERATIONS

Each of the cardinal symptoms of NPH is commonly seen in the elderly and occurs in multiple disease processes; therefore, differential diagnoses should always be considered carefully.

CAUTION

Shunt complications, including subdural or intracerebral hematoma, may occur in 30% to 40% of patients. In one retrospective study spanning 10 yr, which included patients with idiopathic as well as other forms of adult hydrocephalus, the shunt failure rate was 32%.

BASIC INFORMATION

DEFINITION

Hydronephrosis in Greek means "water inside the kidney" and is an anatomic dilation of the collecting system of the kidneys (renal pelvis and/or calyces). When combined with dilation of the ureters, this is known as hydroureteronephrosis. Hydronephrosis is not a specific diagnosis and is *not* synonymous with obstruction. Hydronephrosis can occur with complete, partial, or no obstruction of urine flow.

SYNONYMS

Pelviectasis
Caliectasis
Pelvocaliectasis
Pyelocaliectasis

ICD-10CM CODES

N13.0	Hydronephrosis with ureteropelvic junction obstruction
N13.1	Hydronephrosis with ureteral stricture, not elsewhere classified
N13.2	Hydronephrosis with renal and ureteral calculous obstruction
N13.30	Unspecified hydronephrosis
N13.39	Other hydronephrosis
Q62.0	Congenital hydronephrosis

EPIDEMIOLOGY & DEMOGRAPHICS

Prevalence from multiple autopsy series ranges from 2% to 4%, with subjects ranging in age from neonates to geriatric patients. Antenatal hydronephrosis is one of the most common findings in prenatal ultrasound scans, affecting up to 5% of pregnancies, with 30% to 40% persisting postnatally. Of these, 40% will resolve spontaneously. Hydronephrosis in children is often caused by congenital and structural abnormalities of the kidneys and ureters, such as ureteropelvic junction obstruction (UPJO) or vesicoureteral reflux (VUR). Hydronephrosis in adults is often a result of obstruction of one or both kidneys, usually caused by stones, tumors, infections, and trauma. Stones remain the commonest cause overall of upper urinary tract obstruction. In adults 20 to 60 yr in age, hydronephrosis is more common in women, secondary to pregnancy/gynecologic causes. During pregnancy, physiologic hydronephrosis (more commonly on the right) occurs in up to 90% of cases and is often asymptomatic. In older patients (age >60 yr), obstruction from prostate enlargement or malignancy is the most common cause.

CLINICAL PRESENTATION

Hydronephrosis may present as an asymptomatic, incidental finding during imaging performed for another purpose. Symptoms often indicate an element of obstruction, and the presentation will depend on the *degree* of obstruction (complete or partial), *chronicity* of obstruction (acute or chronic), and *anatomic* factors (unilateral, bilateral and intrinsic or extrinsic in the ureter).

HISTORY:

- Pain is usually present along the flank with radiation toward the ipsilateral groin or lower abdominal quadrant. If onset is sudden and severe, consider a ureteral stone. If the pain is induced by diuresis (e.g., following consumption of alcohol), consider UPJO ("Dietl crisis"). When obstruction is subacute to chronic, symptoms may be vague, less intense, or absent, and may wax and wane in severity (colic). Extrinsic compression (e.g., malignancy-associated compression of ureters) usually has a more insidious onset compared with intrinsic obstruction (e.g., ureteral stone or blood clot).
- Nausea and vomiting are typically associated with acute obstruction, most often from an intrinsic obstructing process.
- Oliguria/anuria may occur with complete, bilateral obstruction, or with an obstructed solitary kidney.
- Urinary symptoms are often absent, unless there is an associated condition, including urinary tract infection, distal ureteral stone, or urinary retention. These voiding symptoms include dysuria, urinary urgency and frequency, pelvic pressure, and discomfort.
- Hematuria: May indicate a stone, urinary tract infection, or malignancy.
- Site of obstruction can relate to the presentation: Upper tract obstruction will frequently present with flank pain, but lower tract obstruction is often associated with voiding symptoms.

PHYSICAL EXAMINATION: A complete physical examination is warranted, but may not be helpful in the assessment of hydronephrosis. Areas to pay special attention to include the following:

- Blood pressure measurement.
- Palpable abdominal masses are rare, except in children or very thin patients with massive hydronephrosis. Costovertebral angle tenderness is not a particularly helpful finding. Palpate and percuss for an enlarged bladder.
- Complete genitourinary and pelvic exams:
  1. Pelvic exam will assess for pelvic masses or pelvic organ prolapse, which is rarely associated with ureteral obstruction.
  2. Digital rectal exam will assess for prostatic abnormality or rectal mass.
  3. Residual urine volume may demonstrate incomplete emptying of the bladder. Residual urine volume can be evaluated indirectly by bedside ultrasonography or directly by catheterization.

ETIOLOGY

Hydronephrosis can be caused by extrinsic or intrinsic factors relative to the urinary tract (Table 1). Causes may be grouped as congenital or acquired.

DIAGNOSIS

Diagnostic workup will depend on the age of the patient, acuity of presentation, if hydronephrosis was diagnosed incidentally, and if associated symptoms are present.

DIFFERENTIAL DIAGNOSIS

- Extrarenal pelvis where no true obstruction exists, but is confused with obstruction
- Urinary stones
- Neoplastic disease: Kidney, ureter, bladder, urethra
- Prostatic hyperplasia
- Urethral stricture
- Neurologic disease producing voiding dysfunction
- Urinary reflux
- Urinary tract infection

TABLE 1 Causes of Hydronephrosis

Obstructive	
Intrinsic to the Urinary Tract	Ureter: Ureteropelvic junction obstruction, ureterovesical junction obstruction, stricture, tumor, ureterocele, stone, blood clot, sloughed papilla, infection, hyperplastic polyp
	Bladder: Malignancy, stone, bladder neck obstruction, urine retention
	Prostate: Benign prostatic enlargement, prostatitis, calculus, abscess, malignancy
	Urethra: Stricture, stone, diverticulum, malignancy, posterior urethral valves, phimosis
Extrinsic to the Urinary Tract	Reproductive system:
	Uterus: Pregnancy, prolapse, fibroids, malignancy
	Ovary: Malignancy, cyst, abscess
	Vascular system:
	Aneurysm: Abdominal aorta, iliac vessel
	Aberrant vessels: Ureteropelvic junction
	Venous: Retrocaval ureter, ovarian vein syndrome
	Gastrointestinal system:
	Inflammatory bowel disease, GI malignancy, abscesses, cysts
	Diseases of the retroperitoneum
	Retroperitoneal fibrosis
	Retroperitoneal malignancy (primary or metastatic deposits)
	Hematoma
	Lymphocele
	Iatrogenic injury
Nonobstructive	
	Vesicoureteral reflux
	Extrarenal pelvis
	Megaureter/megacalycosis
	Pyelonephritis

GI, Gastrointestinal.

- Medication effects
- Trauma
- Congenital abnormality of urinary tract
- Urinary retention
- Retroperitoneal fibrosis
- Urinary trauma
- Iatrogenic injuries

LABORATORY TESTS

- **Evaluation of kidney function** by blood urea nitrogen and creatinine. If azotemia is present, bilateral obstruction or unilateral obstruction of a solitary kidney has occurred.
- **Evaluation of electrolyte abnormalities** including hypo- or hypernatremia, hyperkalemia, and low bicarbonate concentration.
- **Urinalysis and sediment examination** may reveal white blood cells, red blood cells, or bacteria in the appropriate setting (e.g., infection, stones). Urine microscopy facilitates crystal identification, which may suggest urinary stone disease. The sediment may be normal in obstructive renal disease.
- **Urine culture** should be sent when urinalysis or presentation suggests urinary tract infection.
- **Urine cytology** when urothelial cancer is suspected.

IMAGING STUDIES

- Ultrasound is an excellent initial test, especially for children and pregnant women. It is a screening test that permits evaluation of the kidneys, portions of the ureters, bladder wall, and bladder volume, and contour of the collecting system and ureters. Point-of-care ultrasound provides early, rapid imaging and aids patient triage and justification for additional imaging. Ultrasound is >90% sensitive and specific for hydronephrosis. The absence of ureteral jets on ultrasound may be an indirect sign of obstruction, but is not definitive (Fig. E1).
- Abdominal, plain film, or kidney, ureter and bladder (KUB) radiographs are of limited value in isolation. These tests complement ultrasound and may be helpful in diagnosing radiopaque kidney or ureteral stones.
- Abdominal CT scan without intravenous contrast medium provides excellent localization of sites of obstruction (Figs. E2 and E3), especially if a ureteral calculus is the cause of obstruction. A normal ureter on an unenhanced CT is considered 2 to 3 mm wide in adults. If kidney function is normal, CT urography (without and then with contrast, and with delayed images of the ureters), provides excellent anatomic information, and is the modality of choice for assessment of possible upper tract tumors or evaluation of incidental hydronephrosis.
- MRI is an alternative to CT. MRI provides detail but cannot directly detect a stone and is expensive. Impaired renal function may preclude gadolinium administration. MRI is considered after other tests are inconclusive or contraindicated, such as in pregnant patients, those with renal insufficiency, and those with contrast allergy.
- Antegrade or retrograde ureterograms/pyelograms are invasive procedures, but can be used if there are contraindications to CT or MRI scans with contrast (e.g., contrast allergy, renal impairment).
- Voiding cystourethrography, frequently used in pediatric patients, can diagnose vesicoureteral reflux and bladder neck or urethral obstruction.
- Diuretic renography (MAG3 renogram) is a functional radioisotopic test that provides differential function of each kidney, and determines if functional obstruction is present.

Rx TREATMENT

ACUTE GENERAL Rx

- Analgesics, antiemetics, and fluids for treatment of pain, nausea, and vomiting
- Antibiotics for urinary tract infection/pyelonephritis

Definitive management:

- Management depends on presence of obstruction, etiology, and location of hydronephrosis. Prompt treatment of infection and relief of obstruction prevent long-term loss of kidney function. Chronic renal obstruction from any cause may produce permanent functional deterioration.
- General principles include the following:
  1. Routine outpatient evaluation for hydronephrosis in asymptomatic or minimally symptomatic patients with no infection, electrolyte derangements, or acute kidney injury.
  2. Surgical treatment is aimed at relieving obstruction when hydronephrosis is associated with urinary tract infection, acute kidney injury, uncontrollable pain, or nausea and vomiting. Surgical treatment is also indicated with complete urinary obstruction from a bilateral obstructing process or unilateral obstruction in a solitary kidney.
  3. Urethral catheter or suprapubic catheter placement is indicated for bladder outlet obstruction.
  4. Ureteral stenting is carried out for decompression of one or both kidneys.
  5. Percutaneous nephrostomy tubes may be required in the setting of extrinsic ureteral compression or when ureteral stenting is not possible or fails.

REFERRAL

Prompt, emergent referral is paramount in the setting of severe symptoms, infection, or impaired renal function.

- Urology for diagnostic and/or therapeutic procedures (pediatric urologist for antenatal or postnatal hydronephrosis)
- Oncology for diagnosed neoplasm
- Gynecology for pregnancy or if female pelvic anatomy is involved
- Nephrology for electrolyte/acid-base disturbances

PEARLS & CONSIDERATIONS

COMMENTS

- Hydronephrosis is not a primary disorder; an underlying etiology must be sought.
- Children often have congenital causes; adults generally have acquired intrinsic or extrinsic causes.
- There are obstructive and nonobstructive causes of hydronephrosis. Further evaluation can be performed without specialty consultation with a computed tomography urogram, magnetic resonance urogram, or diuretic renogram.
- Prompt renal decompression is critical when hydronephrosis is associated with infection, severe kidney injury, and/or electrolyte abnormalities.

PREVENTION

Timely and appropriate management of acute kidney obstruction prevents long-term kidney damage. Hydronephrosis may persist after relief of the obstructing cause.

Wein AJ: Management of upper urinary tract obstruction. In *Campbell-Walsh Urology*, ed 11, Philadelphia, 2016, Elsevier WB Saunders.

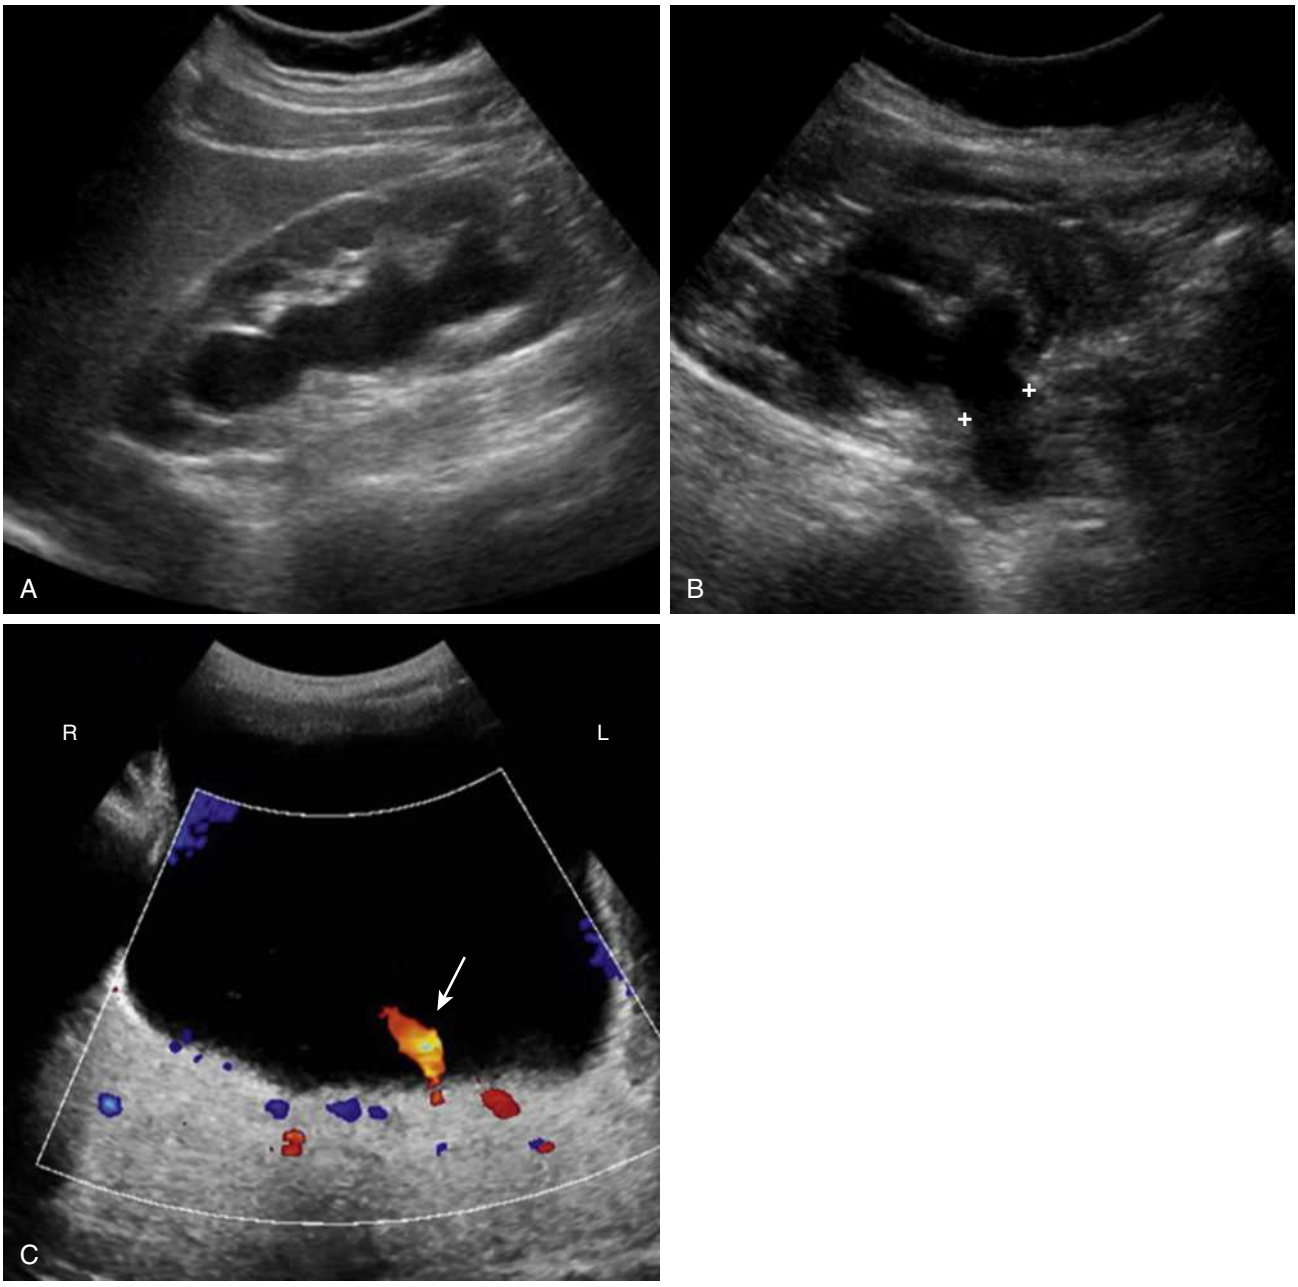

FIG. E1 Renal ultrasound demonstrating hydronephrosis of the right kidney. A, Sagittal image. **B,** Transverse image demonstrating a dilated renal pelvis. **C,** Transverse image of the bladder demonstrating a ureteral jet *(arrow)* on the left side but no ureteral jet on the right, which may suggest obstruction on that side.

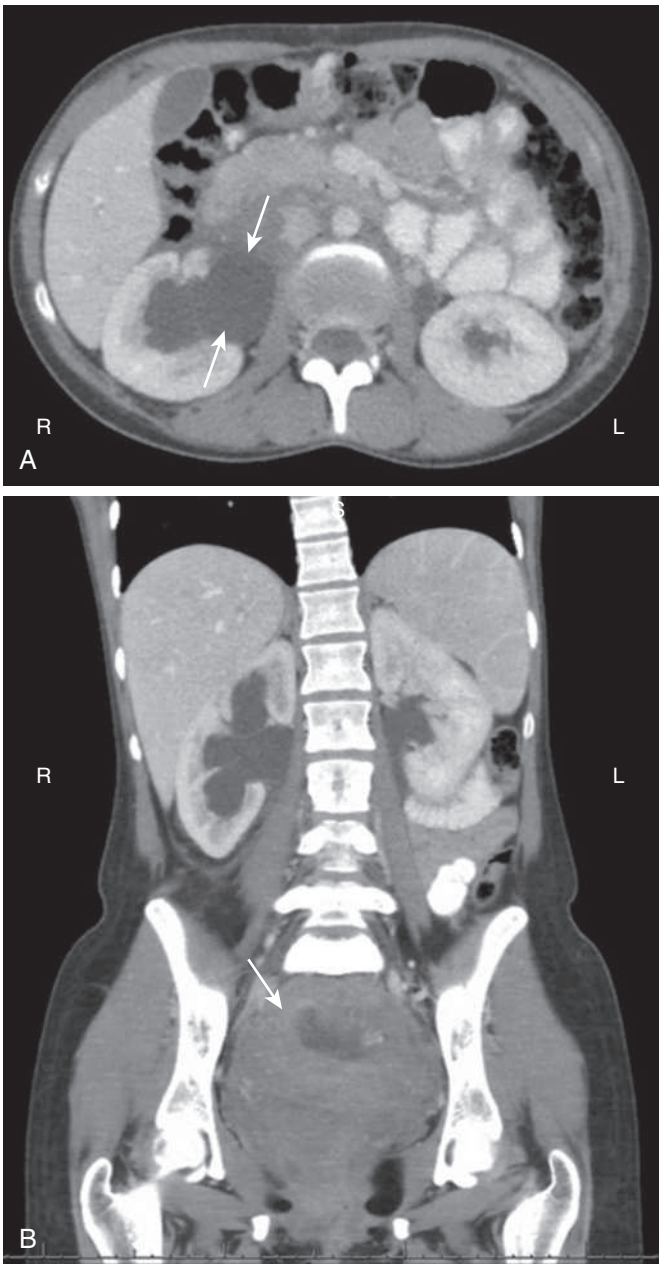

FIG. E2 Computed tomography scan of the abdomen showing a grossly hydronephrotic kidney on the right. A, Cross-sectional image. Arrows highlight the dilated renal pelvis. Sequential sections demonstrate that the ureter was dilated along its length to the distal ureter, where it was being compressed by a large pelvic mass. **B,** Coronal image. This again shows the right-sided hydronephrosis and the large pelvic mass *(arrow).*

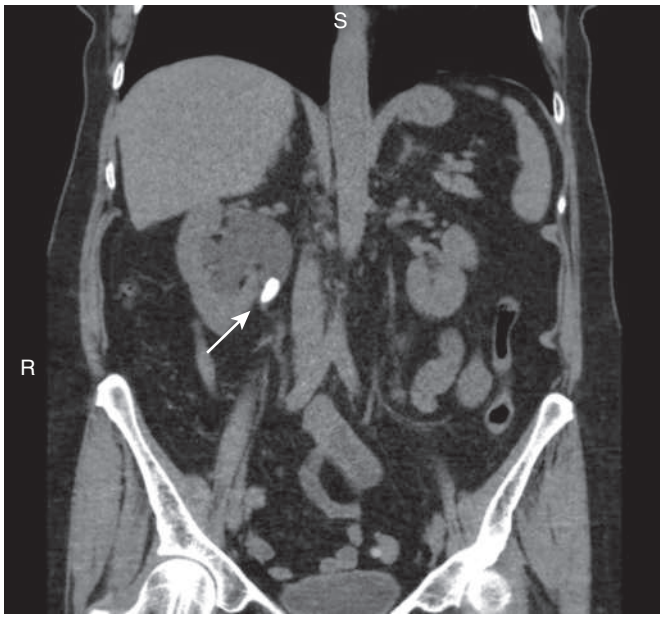

FIG. E3 Coronal computed tomography scan of abdomen showing a grossly hydronephrotic kidney on the right secondary to a large (1.5 cm × 0.9 cm) ureteropelvic junction stone *(arrow).*

BASIC INFORMATION

DEFINITION

Hypercholesterolemia refers to a blood cholesterol measurement ≥200 mg/dl.

SYNONYMS

Hyperlipidemia
Hypercholesteremia
Dyslipidemia
Type II familial hyperlipoproteinemia

ICD-10CM CODE
E78.0 Pure hypercholesterolemia

EPIDEMIOLOGY & DEMOGRAPHICS

- Over 105 million (37%) adults in the U.S. have total blood cholesterol levels higher than 200 mg/dl. Of this group, more than 36 million adults have extremely high-risk cholesterol levels over 240 mg/dl (13%).
- For men over the age of 20 yr, approximately 48% of white men, 45% of black men, and 50% of Hispanic men have high blood cholesterol.
- For women over the age of 20, approximately 50% of white women, 42% of black women, and 50% of Hispanic women have hypercholesterolemia.
- Prevalence of hypercholesterolemia increases with increasing age.
- According to NHANES data for 2009 to 2010, about 47% of adults had at least one of three risk factors for cardiovascular disease—uncontrolled high blood pressure, uncontrolled high levels of low-density lipoproteins (LDL) cholesterol, or current smoking.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- A detailed medication history should be performed because some medications may affect lipid levels (e.g., thiazides, corticosteroids, beta-blockers, and estrogens).
- The physical examination should include measurements of BMI and BP, thyroid and liver assessments, and examining peripheral pulses including carotids for bruits.
- Physical findings, particularly in the familial forms may include:
  1. Tendon xanthomas
  2. Xanthelasma
  3. Arcus corneae
  4. Arterial bruits (young adulthood)

ETIOLOGY

Primary:
- Genetics
- Obesity
- Dietary intake

Secondary:
- Hypothyroidism
- Diabetes mellitus
- Nephrotic syndrome
- Obstructive liver disease: Hepatoma, extrahepatic biliary obstruction, primary biliary cirrhosis
- Alcohol or tobacco use
- Dysgammaglobulinemia (multiple myeloma, SLE)
- Drugs: Oral contraceptives, progesterone, corticosteroids, thiazide diuretics, β-blockers, androgenic steroids, retinoic acid derivatives, protease inhibitors

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Always consider underlying secondary causes for the elevated cholesterol.
- Patients with very high LDL cholesterol usually have genetic forms of hypercholesterolemia (see "Hyperlipoproteinemia, Primary"). Early detection of these cases and family testing to identify similarly affected relatives is important.
- Metabolic syndrome:
  1. A constellation of lipid and nonlipid risk factors of a metabolic origin
  2. Diagnosed when three or more of the following are present: abdominal obesity (waist circumference >40 in in men and >35 in in women); fasting triglycerides >150 mg/dl; HDL <40 mg/dl in males and <50 mg/dl in females; systolic BP >130 mmHg and diastolic BP >85 mmHg; fasting glucose >110 mg/dl

WHO SHOULD BE SCREENED:
- AACE recommends screening of patients >20 yr of age for elevated cholesterol every 5 yr, males >45 yr and females >55 yr of age every 1 to 2 yr, and >65 yr of age every yr up to 75 yr of age regardless of CAD risk status. Patients above 75 yr of age with multiple CAD risk factors should still continue to get screened annually.
- The USPSTF supports routine screening for men aged >35 yr and women aged >45 yr by measurement of nonfasting total and HDL cholesterol alone.
- In 2010, the USPSTF recommended routine screening for overweight and obesity in persons aged <20 yr.
- In 2011, ACC/AHA recommended screening for hypertriglyceridemia by a nonfasting measurement. A nonfasting level of <200 mg/dl is commensurate with an optimal level of <100 mg/dl and no further testing is required. However, a nonfasting level of >200 mg/dl warrants further testing with a fasting lipid profile.

LABORATORY TESTS

- Obtain a lipid profile. A fasting lipid panel has been traditionally preferred over a nonfasting lipid profile; however, this recommendation has come into question, and expert consensus statements from Canada and Europe recommend nonfasting lipid testing as the new standard for lipid measurement. In nonfasting patients, triglyceride levels ≥175 mg/dl should be considered elevated as compared with <150 mg/dl for fasting panels. Fasting lipid panels are preferred for patients with triglycerides over 400 mg/dl.
- Perform a workup for secondary causes if clinically indicated, such as TSH, metabolic profile, LFTs, and fasting glucose.

TREATMENT

NONPHARMACOLOGIC THERAPY

- First line of treatment: Dietary therapy can result in 5% to 15% reduction in LDL cholesterol level.
- Composition of the **TLC diet:**
  1. Total fat 25% to 30% of total calories
  2. Polyunsaturated fat up to 10% of total calories
  3. Monounsaturated fat up to 20% of total calories
  4. Saturated fats <7% of total calories
  5. Carbohydrate 50% to 60% of total calories
  6. Protein 15% of total calories
  7. No more than 200 mg/day of cholesterol
  8. Fiber 20 to 30 g/day
- Increased physical activity: Encourage 30 min of moderately intense physical activity, four to six times a wk (e.g., brisk walking, riding stationary bike, water aerobics)
- Maintenance of a healthy weight
- Avoidance of tobacco products
- Counseling on CAD risk factors (Table 1)
- Plant-based diets (including stanol-containing margarines, oat bran, and nuts) have shown effectiveness in controlling lipids.

ACUTE GENERAL Rx

No acute treatment needed

CHRONIC Rx

- Box 1 summarizes the key recommendations for the treatment of blood cholesterol to reduce ASCVD (atherosclerotic cardiovascular disease) risk in adults.
- The guidelines identify four high-risk groups that benefit from statin therapy:
  1. Patients with clinical ASCVD (Table 2, Fig. 1)
  2. LDL ≥190 mg/dl
  3. DM aged 40 to 75 yr and LDL 70 to 189 mg/dl
  4. 10-yr risk for ASCVD ≥7.5% and LDL 70 to 189 mg/dl

TABLE 1 Risk Factors for Heart Disease

1. Cigarette smoking
2. Hypertension (BP ≤140/90 mm Hg or on medications)
3. Low HDL cholesterol (<40 mg/dl)*
4. Family history of premature CHD (<55 yr in first-degree male relative or <65 yr in first-degree female relative)
5. Age (men ≥45 yr, women ≥55 yr)

*HDL cholesterol >60 mg/dl counts as a negative risk factor; its presence removes one risk factor from the total count.
BP, Blood pressure; *CHD,* congenital heart disease; *HDL,* high-density lipoprotein cholesterol.

BOX 1 2013 ACC/AHA Summary of Key Recommendations for the Treatment of Blood Cholesterol to Reduce ASCVD Risk in Adults

A. Heart-healthy lifestyle habits should be encouraged for all individuals
B. The appropriate intensity of statin therapy should be initiated or continued
   1. Clinical ASCVD*
      a. Age 75 yr or less and no safety concerns: High-intensity statin (class I, level A)
      b. Age 75 yr or safety concerns: Moderate-intensity statin (class I, level A)*
   2. Primary prevention: Primary LDL-C 190 mg/dl or greater
      a. Rule out secondary causes of hyperlipidemia (class I, level B)
      b. Age 21 yr or older: High-intensity statin (class I, level B)
      c. Achieve at least a 50% reduction in LDL-C (class IIa, level B)
      d. LDL-C lowering nonstatin therapy may be considered to further reduce LDL-C (class IIb, level C)
   3. Primary prevention: Diabetes, 40 to 75 yr of age, and LDL-C 70 to 189 mg/dl
      a. Moderate-intensity statin (class I, level A)
      b. Consider high-intensity statin when 7.5% or greater 10-yr ASCVD risk using the Pooled Cohort Equations (class IIa, level B)†‡
   4. Primary prevention: No diabetes, 40 to 75 yr of age, and LDL-C 70 to 189 mg/dl
      a. Estimate 10-yr ASCVD risk using the Risk Calculator based on the Pooled Cohort Equations in those *not* receiving a statin; estimate risk every 4 to 6 yr (class I, level B)
      b. To determine whether to initiate a statin, engage in a clinician-patient discussion of the potential for ASCVD risk reduction, adverse effects, drug-drug interactions, and patient preferences
      c. Reemphasize heart-healthy lifestyle habits and address other risk factors (class IIa, level C)
         i. 7.5% or greater 10-yr ASCVD risk: Moderate- or high-intensity statin (class I, level A)
         ii. 5% to 7.5% 10-yr ASCVD risk: Consider moderate-intensity statin (class IIa, level B)
         iii. Other factors may be considered: LDL-C 160 mg/dl or greater, family history of premature ASCVD, hs-CRP 2.0 mg/L or greater, CAC score 300 Agatston units or greater, ABI less than 0.9, or lifetime ASCVD risk (class IIb, level C)
   5. Primary prevention when LDL-C is less than 190 mg/dl and age is less than 40 or more than 75 yr, or less than 5% 10-yr ASCVD risk
      a. Statin therapy may be considered in selected individuals (class IIb, level C)
   6. Statin therapy is not routinely recommended for individuals with NYHA class II-IV heart failure or who are receiving maintenance hemodialysis
C. Regularly monitor adherence to lifestyle and drug therapy with lipid and safety assessments
   1. Assess adherence, response to therapy, and adverse effects within 4 to 12 wk following statin initiation or change in therapy (class I, level A)
      a. Measure a fasting lipid panel (class I, level A)
      b. Do not routinely monitor ALT or CK unless symptomatic (class IIa, level C)
      c. Screen and treat type 2 diabetes according to current practice guidelines. Heart-healthy lifestyle habits should be encouraged to prevent progression to diabetes (class I, level B)
      d. Anticipated therapeutic response: Approximately 50% or greater reduction in LDL-C from baseline for high-intensity statin and 30% to 50% for moderate-intensity statin (class IIa, level B)
         i. Insufficient evidence for LDL-C or non–HDL-C treatment targets from RCTs
         ii. For those with unknown baseline LDL-C, an LDL-C less than 100 mg/dl was observed in RCTs of high-intensity statin therapy
      e. Less than anticipated therapeutic response:
         i. Reinforce improved adherence to lifestyle and drug therapy (class I, level A)
         ii. Evaluate for secondary causes of hyperlipidemia if indicated (class I, level A)
         iii. Increase statin intensity, or if on maximally tolerated statin intensity, consider addition of nonstatin therapy in selected high-risk individuals (class IIb, level C)§
      f. Regularly monitor adherence to lifestyle and drug therapy every 3 to 12 mo once adherence has been established. Continue assessment of adherence for optimal ASCVD risk reduction and safety (class I, level A)
D. In individuals intolerant of the recommended intensity of statin therapy, use the maximally tolerated intensity of statin (class I, level B). If there are muscle or other symptoms, establish that they are related to the statin (class IIa, level B)

*Clinical ASCVD includes acute coronary syndromes, history of MI, stable or unstable angina, coronary or other arterial revascularization, stroke, TIA, or peripheral arterial disease presumed to be of atherosclerotic origin.
†Estimated 10-yr or "hard" ASCVD risk includes first occurrence of nonfatal MI, CHD death, and nonfatal and fatal stroke as used by the Risk Assessment Work Group in developing the Pooled Cohort Equations on the basis of age, sex, smoking status, total cholesterol level, HDL-C level, systolic blood pressure, and the use of antihypertensive therapy.
‡These factors may include primary LDL-C of 160 mg/dl or greater or other evidence of genetic hyperlipidemias; family history of premature ASCVD with onset at less than 55 yr of age in a first-degree male relative or at less than 65 yr of age in a first-degree female relative; hs-CRP 2 mg/L or greater; CAC score 300 Agatston units or greater or 75th percentile or greater for age, sex, and ethnicity; ABI less than 0.9; or lifetime risk of ASCVD. Additional factors that might aid in individual risk assessment could be identified in the future.
§High-risk individuals include those with clinical ASCVD, an untreated LDL-C 190 mg/dl or greater, suggesting genetic hypercholesterolemia, or individuals with diabetes 40 to 75 yr of age and LDL-C 70 to 189 mg/dl.
ABI, Ankle-brachial index; *ACC,* American College of Cardiology; *AHA,* American Heart Association; *ALT,* alanine aminotransferase, a test of hepatic function; *ASCVD,* atherosclerotic cardiovascular disease; *CAC,* coronary artery calcium; *CHD,* coronary heart disease; *CK,* creatine kinase, a test of muscle injury; *HDL-C,* high-density lipoprotein cholesterol; *hs-CRP,* high-sensitivity C-reactive protein; *LDL-C,* low-density lipoprotein cholesterol; *MI,* myocardial infarction; *NYHA,* New York Heart Association; *RCTs,* randomized controlled trials; and *TIA,* transient ischemic attack.
From 2013 ACC/AHA guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines, *J Am Coll Cardiol* 63(25 Pt B):2889-2934, 2014.

TABLE 2 Atherosclerotic Cardiovascular Disease

1. Coronary heart disease: Acute coronary syndromes, history of myocardial infarction, stable or unstable angina, coronary or other arterial revascularization
2. Stroke or transient ischemic attack
3. Peripheral arterial disease

- The 10-yr risk of ASCVD is calculated with the risk calculator available at http://my.americanheart.org/cvriskcalculator
- ASCVD events are reduced by using the maximum tolerated statin intensity in the above groups shown to benefit the most (Tables 3 and 4).
- Additional factors such as CRP >2 mg/L, primary LDL >160, genetic hyperlipidemias, family history of premature CHD, ABI <0.9, and coronary artery calcium score (CAD) assessed with CT may be used in patients who are not in one of four statin benefit groups and for whom a decision to initiate statin therapy is otherwise unclear. Statins are generally beneficial in patients at intermediate risk and selected patients with borderline risk who have a calcium score that is 100 or higher or who are in

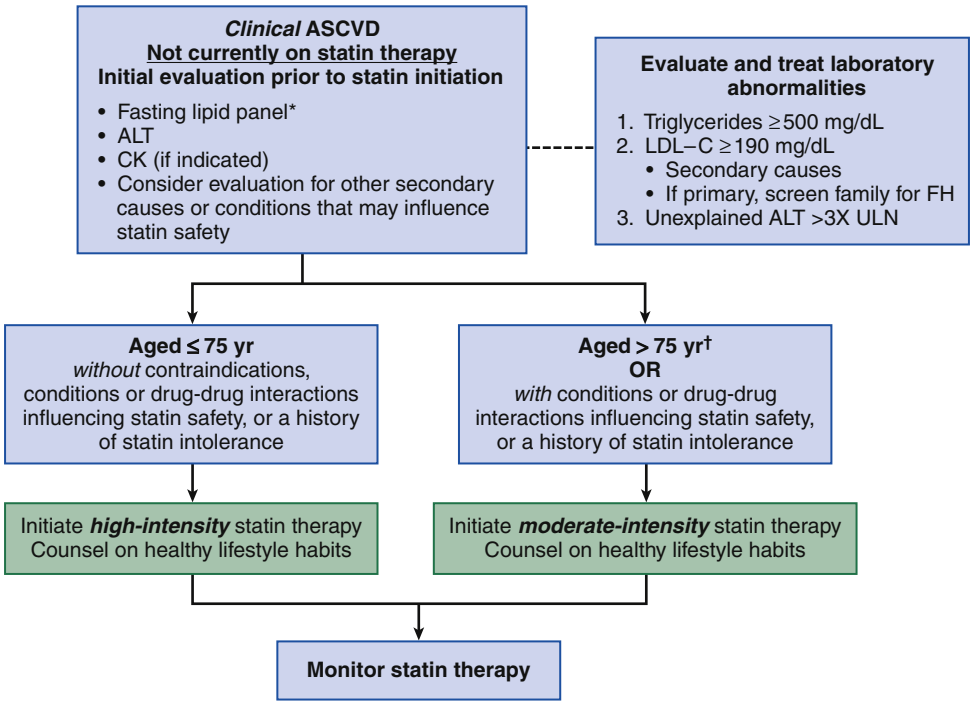

FIG. 1 Initiating statin therapy in individuals with clinical ASCVD. *Fasting lipid panel is preferred. In a nonfasting individual, a nonfasting non-HDL–C >220 mg/dl may indicate genetic hypercholesterolemia that requires further evaluation or a secondary etiology. If nonfasting triglycerides are >500 mg/dl, a fasting lipid panel is required. †It is reasonable to evaluate the potential for ASCVD benefits and for adverse effects and to consider patient preferences in initiating or continuing a moderate- or high-intensity statin in individuals with ASCVD >75 yr of age. *ALT,* Alanine transaminase; *ASCVD,* atherosclerotic cardiovascular disease; *CK,* creatine kinase; *FH,* familial hypercholesterolemia; *HDL–C,* high-density lipoprotein cholesterol; *LDL–C,* low-density lipoprotein cholesterol; *ULN,* upper limit of normal. (Modified from Stone NJ et al: 2013 ACC/AHA guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines, *J Am Coll Cardiol,* 2013. In Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015, Elsevier.)

TABLE 3 Statin Intensity Therapies

High Intensity (Decrease LDL-C ≥50%)	Moderate Intensity (Decrease LDL-C 30%-49%)
Atorvastatin 40-80 mg	Atorvastatin 10-20 mg
Rosuvastatin 20-40 mg	Rosuvastatin 5-10 mg
—	Simvastatin 20-40 mg
—	Pravastatin 40-80 mg
—	Lovastatin 40 mg
—	Fluvastatin XL 80 mg
—	Fluvastatin 40 mg bid
—	Pitavastatin 2-4 mg

bid, Twice a day; *LDL-C,* low-density lipoprotein cholesterol.
From Stone N et al: 2013 ACC/AHA guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines, *J Am Coll Cardiol* 63(25 Pt. B):2889, 2014.

TABLE 4 Statin Benefit Groups and Recommended Therapy

Statin Benefit Group	High Intensity	Moderate Intensity	Additional Testing
Clinical ASCVD	Yes	Consider†	None
Primary LDL-C >190 mg/dl	Yes	Consider†	None
Diabetes without ASCVD and 10-yr risk ≥7.5%*	Yes	Consider†	None
Diabetes without ASCVD and 10-yr risk <7.5%*	Consider‡	Yes	Case-by-case
Primary prevention and 10-yr risk ≥7.5%*	Consider‡	Yes	Case-by-case
Primary prevention and 10-yr risk <7.5%*	Consider‡	Consider‡	Case-by-case

*Based on Pooled Cohort Risk Equations.
†If age >75 yr or not candidate for high intensity.
‡If abnormal high-sensitivity C-reactive protein, coronary artery calcium, ankle-brachial index, lifetime risk.
ASCVD, Atherosclerotic cardiovascular disease; *LDL-C,* low-density lipoprotein cholesterol.
From Boyden TF et al: Implementing new guidelines in the management of blood cholesterol, *Am J Med* 127:705, 2014.

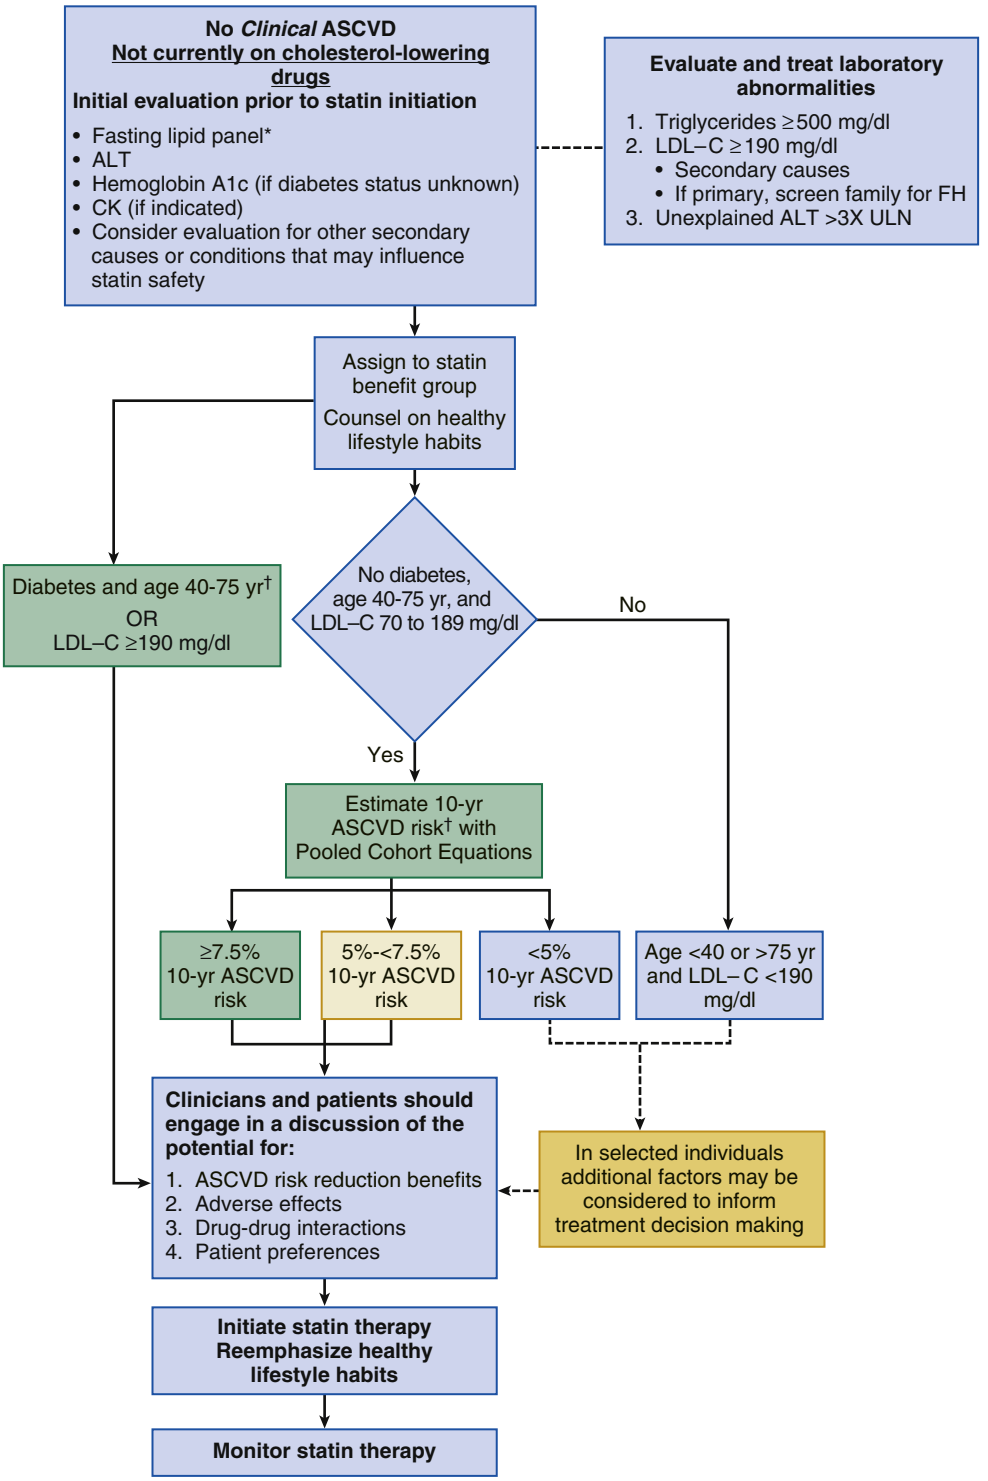

FIG. 2 Initiating statin therapy in individuals without clinical ASCVD. *Fasting lipid panel is preferred. In a nonfasting individual, a nonfasting non-HDL–C>220 mg/dl may indicate genetic hypercholesterolemia that requires further evaluation or a secondary etiology. If nonfasting triglycerides are >500 mg/dl, a fasting lipid panel is required. †The Pooled Cohort Equations can be used to estimate 10-yr ASCVD risk in individuals with and without diabetes. *ALT,* Alanine transaminase; *ASCVD,* atherosclerotic cardiovascular disease; *CK,* creatine kinase; *FH,* familial hypercholesterolemia; *LDL–C,* low-density lipoprotein cholesterol; *ULN,* upper limit of normal. (Modified from Stone NJ et al: 2013 ACC/AHA guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines, *J Am Coll Cardiol,* 2013. In Mann DL et al: *Braunwald's heart disease,* ed 10, Philadelphia, 2015. Elsevier.)

the 75th percentile or higher for their age, sex, and race. Statins should also be considered in persons with scores of 1 to 99, particularly if they are 55 yr of age or older.[1]

- Percent reduction in LDL cholesterol is used as a guide to compliance and adherence to therapy in the 2018 AHA/ACC Revised Clinical Practice Guidelines. Studies have shown that compared with less-intensive LDL-C lowering, more intensive lowering reduces all-cause mortality and cardiovascular mortality; patients with higher baseline LDL-C have greater benefit.
- Moderate-intensity statin therapy should be continued for individuals >75 yr of age for secondary prevention. However, factors such as comorbidities, safety, and priorities of care should be considered before initiating statins for primary prevention of ASCVD.
- Fig. 2 illustrates initiating statin therapy in individuals without clinical ASCVD.
- Adherence to lifestyle and to statin therapy should be reiterated with patients before the addition of a nonstatin drug.
- High-risk patients with a suboptimal response to statins who are unable to tolerate a recommended intensity or who are completely statin intolerant may benefit from the addition of a nonstatin cholesterol-lowering agent such as ezetimibe.
- Table E5 summarizes oral drugs affecting lipoprotein metabolism.
- PCSK9 (proprotein convertase subtilisin/kexin type 9) inhibitors (alirocumab [Praluent], evolocumab [Repatha]) are indicated as adjunct to diet and maximally tolerated statin therapy for the treatment of adults with heterozygous familial hypercholesterolemia or clinical atherosclerotic cardiovascular disease, who require additional lowering of LDL cholesterol. PCSK9 inhibitors lower risk for ischemic cardiovascular events in persons with stable CAD and elevated atherogenic lipoproteins despite statin therapy. These medications are administered by subcutaneous injection and are expensive.
- The management of metabolic syndrome includes weight reduction, increased physical activity, and treatment of hypertension, elevated triglycerides, and low HDL cholesterol.
- According to recent studies, each 40 mg/dl reduction in LDL cholesterol by statin therapy confers a 20% reduction in ASCVD. In other words, a relative risk reduction of 30% in ASCVD by moderate-intensity therapy and 45% by high-intensity therapy has been approximated.
- Recent trials have shown that bempedoic acid, an inhibitor of ATP citrate lyase, reduces LDL cholesterol. The addition of bempedoic acid to maximally tolerated statin therapy did not lead to a higher incidence of overall adverse events than placebo and led to significant lowering of LDL cholesterol.[2]

DISPOSITION AND FOLLOW-UP

- Baseline LFT testing should be done before initiation of statin therapy and as clinically indicated thereafter.
- CK level monitoring is not recommended unless a patient reports muscle weakness or myalgias.
- Statin therapy should be monitored by repeating a lipid profile within 4 to 12 wk after initiation of therapy.
- Counseling about behavioral lifestyle changes and risk factors for CHD should be provided at every follow-up visit.
- Adverse effects of statin-associated diabetes varies by statin intensity: 1 excess case of diabetes per 1000 treated individuals with moderate-intensity statin and 3 excess cases of diabetes per 1000 treated individuals with high-intensity statin per yr has been reported. Myopathy and hemorrhagic stroke incidence is around 1 excess case per 10,000 treated individuals.
- Per new guidelines, those who develop diabetes during statin therapy should be advised to continue it to reduce their risk of ASCVD events and should adhere to a heart-healthy diet, engage in physical activity, cease tobacco use, and maintain a healthy body weight (Table E5).
- Maintain patients on simvastatin 80 mg only if they have been taking this dose for 12 or more mo without evidence of muscle toxicity.
- Do not start new patients on simvastatin 80 mg.
- Place patients who do not meet their LDL goal on simvastatin 40 mg on alternative LDL-C-lowering treatment(s) to reach goal.

REFERRAL

Patients with rare lipid disorders, hyperlipoproteinemias, patients resistant to treatment, on complex regimens, and with evidence of disease progression despite treatment should be referred to a lipid specialist.

PEARLS & CONSIDERATIONS

COMMENTS

- New features in the 2018 clinical practice guidelines compared to the 2013 guidelines support the addition of nonstatin medications (ezetimibe or PCSK9 inhibitors) to statin therapy for secondary prevention in patients at very high risk. In primary prevention, a clinical patient risk discussion is strongly recommended before a decision is made about statin treatment. Among intermediate-risk patients, identification of risk-enhancing factors and coronary calcium testing is recommended when considering the use of a statin.[3]
- Familial hypercholesterolemia (FH) is characterized by elevated cholesterol concentrations early in life. Untreated FH is associated with premature cardiovascular disease in adulthood. Screening can detect FH in children, and lipid-lowering treatment in childhood can reduce lipid concentrations in the short term, with little evidence of harm. A 20-yr follow-up study of statin therapy has shown that initiation of statin therapy during childhood in patients with FH slows the progression of carotid intima media thickness and reduces the risk of cardiovascular disease in adulthood.[4]
- The American Academy of Pediatrics (AAP) guideline (*Pediatrics* 122:198, 2008) recommends consideration toward pharmacologic treatment for children with LDL >190 mg/dl or >160 mg/dl if other risk factors are present.
- *HDL cholesterol efflux capacity* refers to the ability of HDL to accept cholesterol from macrophages, which is a key step in reverse cholesterol transport. It is inversely associated with the incidence of cardiovascular events and may be a useful biomarker when added to traditional risk factors.

TABLE E5 Drugs Affecting Lipoprotein Metabolism

Drug Class	Agents and Daily Doses	Lipid/Lipoprotein Effects	Side Effects	Contraindications
HMG-CoA reductase inhibitors (statins)	Lovastatin (10-40 mg) Pravastatin (10-80 mg) Simvastatin† (5-80 mg) Fluvastatin (20-40 mg) Atorvastatin (10-80 mg) Rosuvastatin (5-40 mg) Pitavastatin (2-4 mg)	LDL↓ 20%-60% HDL↑ 5%-15% TG↓ 7%-30%	Myalgias, myositis Increased liver enzymes New-onset diabetes (with intensive therapy) Unproven concerns about memory loss	Active or chronic liver disease Pregnancy Concomitant use of certain drugs*
Bile acid sequestrants	Colestipol (5-20 g) Colesevelam‡ (2.6-3.8 g) Cholestyramine (4-16 g)	LDL↓ 15%-30% HDL↑ 3%-5% TG No change or increase	Gastrointestinal distress, constipation, drug interaction, hypertriglyceridemia Decreased absorption of fat-soluble vitamins	TG >300 mg/dl GI motility disorder
Omega-3 fatty acids	Fish oils (4-6 g)	TG↓ 45% HDL↑ 13%	Increased bleeding time Nausea	Caution with anticoagulant therapy
Nicotinic acid	Immediate release (niacin) (1.5-3 g) Extended release (Niaspan) (1-2 g)	LDL↓ 5%-25% HDL↑ 15%-35% TG↓ 20%-50%	Flushing Hyperglycemia Hyperuricemia (or gout) Upper GI distress Hepatotoxicity	Chronic liver disease Severe gout Diabetes Peptic ulcer disease Pregnancy/lactation
Fibric acids	Gemfibrozil (600 mg bid) Fenofibrate (45-145 mg)	LDL↓ 5%-20% HDL↑ 10%-20% TG↓ 20%-50%	Dyspepsia Gallstones Myopathy (especially with concomitant use of gemfibrozil and statins)	Severe renal disease (dose adjustment for fenofibrate) Severe hepatic disease Caution with statins Can worsen LDL cholesterol
Ezetimibe (cholesterol absorption inhibitor)	Ezetimibe (10 mg)	LDL↓ 18% HDL↑ 1% TG↓ 8%	Abdominal pain; myalgias	Liver disease Avoid with resins and fibrates

*Cyclosporine, macrolide antibiotics, various antifungal agents, and cytochrome P-450 inhibitors (fibrates and niacin should be used with appropriate caution).
†Dosages of 80 mg of simvastatin are no longer recommended. Potential interactions with amlodipine and ranolazine warrant doses ≤2 mg daily.
‡Colesevelam reduces glucose and A1c ~0.5% and has been approved for treatment of diabetes with dyslipidemia.
GI, Gastrointestinal; *HDL,* high-density lipoprotein cholesterol; *HMG-CoA,* 3-hydroxy-3-methylglutaryl coenzyme A; *LDL,* low-density lipoprotein cholesterol; *TG,* triglyceride.
Modified from The National Cholesterol Education Program, *JAMA* 285:2486, 2001. In Boyden TF et al: Implementing new guidelines in the management of blood cholesterol, *Am J Med* 127:705, 2014.

Hypercoagulable State PTG

BASIC INFORMATION

DEFINITION

Hypercoagulable state is an inherited or acquired condition associated with an increased risk of thrombosis. A classification of hypercoagulable states is described in Table 1.

SYNONYM

Thrombophilia

ICD-10CM CODES

D68.5 Primary thrombophilia
D68.6 Other thrombophilia
D68.8 Other specified coagulation defects
D68.9 Coagulation defect, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE, PREVALENCE, PREDOMINANT SEX, AND AGE: See Table 2. Significant variations in the prevalence rates and thrombotic risks for hypercoagulable states are reported. This may reflect geographic variation in the prevalence of genetic defects, different populations, or the presence of other unidentified thrombophilic risk factors. When thrombosis occurs, it is often associated with an acquired risk factor (e.g., surgery, pregnancy, oral contraceptive [OC] use).

GENETICS:

- Most people with a genetic defect will not have thrombotic disease.
- Approximately half of patients with unprovoked thrombosis have an identifiable inherited thrombophilia. There is a low risk of recurrent thrombosis in patients with a single genetic defect. Multiple genetic defects are not uncommon (1% to 2% prevalence in patients with idiopathic venous thromboembolism [VTE]); a strong synergistic effect occurs when multiple defects are present.

RISK FACTORS: Family history of thrombosis, increasing age, tobacco use, immobility, surgery, prior history of deep vein thrombosis (DVT) pregnancy, hormone replacement therapy, trauma, connective tissue disease, underlying malignancy, medications (megestrol acetate, tamoxifen, oral contraceptives). Potential prothrombotic states are summarized in Table 3.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Inherited thrombophilia is usually associated with VTE, most commonly DVT
- Some acquired thrombophilias are associated with arterial thrombosis. Table 2 describes sites of thrombosis according to coagulation defect
- Pregnancy complications
- Medical conditions associated with increased risk of thrombosis

ETIOLOGY

- Thrombosis is often a multifactorial process with genetic, environmental, and acquired factors. Table E4, Table E5, Table E6, and Table E7 describe causes of acquired and inherited deficiencies in antithrombin, protein C, and protein S.
- Thrombotic risk increases with use of OCs or hormone replacement therapy (HRT) and during the pregnancy/postpartum period.
- Adverse pregnancy outcomes may be caused by thrombosis of the uteroplacental circulation.

TABLE 1 Classification of Hypercoagulable States

Hereditary	Mixed	Acquired
Loss of Function		
Antithrombin deficiency	Hyperhomocysteinemia	Previous venous thromboembolism
Protein C deficiency	Obesity	Pregnancy, puerperium
Protein S deficiency	Cancer	
		Drug-induced:
		Heparin-induced thrombocytopenia
		Prothrombin complex concentrates
		L-asparaginase
		Hormonal therapy
Gain of Function		
Factor V Leiden	Postoperative	
Prothrombin FII G20210A	Myeloproliferative disorders	
Elevated factor VIII, IX, or XI		

Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE 3 Potential Prothrombotic States

Congenital

Deficiency of anticoagulants
AT-III, protein C or protein S, plasminogen
Resistance to cofactor proteolysis
Factor V Leiden
High levels of procoagulants
Prothrombin 20210 mutation
Damage to endothelium

Acquired

Obstruction to flow indwelling lines
Pregnancy
Polycythemia/dehydration
Immobilization
Injury
Trauma, surgery, exercise
Inflammation
IBD, vasculitis, infection, Behçet syndrome
Hypercoagulability
Pregnancy
Malignancy
Antiphospholipid syndrome
Nephrotic syndrome
Oral contraceptives L-Asparaginase

Rare Other Entities

Congenital dysfibrinogenemia
Acquired
Paroxysmal nocturnal hemoglobinuria
Thrombocythemia
Vascular grafts

AT-III, Antithrombin III; *IBD,* inflammatory bowel disease.
From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, WB Saunders.

TABLE 2 Hypercoagulable Conditions

	Prevalence in General Population (%)	Prevalence in Population with Thrombosis (%)	A/V Events	Relative Risk of Thrombosis
FVL mutation	5% of whites; rare in nonwhites	12%-40%	V	Heterozygous: 3-7; homozygous: 80
Prothrombin G20210A mutation	3% of whites; rare in nonwhites	6%-18%	V	3
AT deficiency	0.02%	1%-3%	V	20-50
PC deficiency	0.2%-0.4%	3%-5%	V	7-15
PS deficiency	0.03%-0.1%	1%-5%	V	5-11
Antiphospholipid antibody syndrome	1%-2%	5%-21%	V + A	2-11

A, Arterial; *AT,* antithrombin; *FVL,* factor V Leiden; *PC,* protein C; *PS,* protein S; *V,* venous.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

INHERITED: Factor V Leiden (FVL) mutation:

- Autosomal-dominant mutation with low penetrance
- Causes activated protein C resistance (APCR); 90% of APCR is caused by FVL mutation
- Most common inherited thrombophilia; accounts for 40% to 50% of cases
- OC use in heterozygous carriers is associated with an eightfold increased risk of VTE compared with noncarriers and a thirty-fivefold increased risk of VTE compared with noncarriers not using OCs
- May be associated with cardiovascular disease in select high-risk subgroups

Prothrombin G20210A mutation:

- Autosomal-dominant mutation with low penetrance
- OC use in heterozygous carriers is associated with a sixteenfold increased risk of VTE compared with noncarriers not using OCs
- May be associated with cardiovascular disease in select high-risk subgroups and young patients with ischemic stroke
- Causes increased mRNA accumulation and protein synthesis, leading to elevated prothrombin plasma concentrations

Protein C, protein S, antithrombin (AT) deficiency:

- Autosomal-dominant inheritance; many mutations identified for each of these conditions
- Decreased level (type I deficiency) or abnormal function (type II deficiency)
- First episode of thrombosis is usually in young adults

Protein C and protein S:

- Homozygous condition is very rare; usually associated with lethal thrombosis in infancy
- Associated with warfarin-induced skin necrosis, which occurs secondary to depletion of vitamin K–dependent anticoagulant factors sooner than procoagulant factors in the first few days of therapy

AT deficiency:

- Most thrombogenic of the inherited thrombophilias; 50% lifetime risk of thrombosis.
- Homozygous condition is very rare, probably not compatible with normal fetal development.
- Arterial thrombosis can occur rarely.
- Can cause heparin resistance.

Other possible causes: Non-O blood group, dysfibrinogenemia, elevated thrombin-activatable fibrinolysis inhibitor, elevated factor IX and factor XI levels

ACQUIRED: Antiphospholipid antibody syndrome (APS):

- Most common cause of acquired thrombophilia
- Can present as arterial or venous thrombosis, recurrent pregnancy loss, and adverse pregnancy outcomes
- Thromboembolic events occur in up to 30% of population; high risk of recurrent thrombosis (up to 70% reported)
- See "Antiphospholipid Antibody Syndrome" for more information

Conditions associated with increased risk of thrombosis:

- Prior thrombosis
- Trauma
- Medical illness: Heart failure, respiratory failure, infection, diabetes mellitus, obesity, nephrotic syndrome, inflammatory bowel disease
- Chronic hemolysis–paroxysmal nocturnal hemoglobinuria, atypical hemolytic uremic syndrome, sickle cell anemia
- Pregnancy (sixfold increased risk of VTE), postpartum, OC use (fourfold increased risk, higher risk with third-generation OCs), transdermal contraceptive patch, HRT (twofold increased risk), tamoxifen, raloxifene
- Immobilization, travel
- Surgery (especially orthopedic), central venous catheters
- Hyperviscosity syndromes
- Myeloproliferative disorders
- Malignancy: Disease or treatment related
- Heparin-induced thrombocytopenia and thrombosis
- Smoking

WORKUP

- History (presence of conditions or use of medications predisposing to thrombosis, family history of thrombosis), physical examination, laboratory tests, imaging studies. Routine investigations to evaluate a patient with thrombosis are summarized in Box 1.
- Age-appropriate cancer screening.
- No consensus exists regarding screening for thrombophilia; few cost-effectiveness or outcomes data are available. Thrombophilia screening is probably overused, as results usually do not change management.
- Thrombophilia screening is not recommended for primary prevention of VTE; some advocate testing prior to OC use or pregnancy in women with a strong family history of thrombosis or thrombophilia. Box 2 summarizes recommendations regarding when to perform a thrombophilia screen. Essential tests for thrombophilia screening are described in Box 3.
- Screening not recommended if VTE was associated with an identified risk factor. A possible exception is thrombosis associated with pregnancy, the postpartum period, or with OC use.
- Provoked by weak triggers in a patient with a strong family history and female family members of childbearing age; consider testing for FVL, prothrombin *G20210A* mutation, protein C, protein S, and AT deficiency. Consider testing for APS if extensive DVT or pulmonary embolism (PE).
- Unprovoked VTE:
  1. Screen individuals for APCR, prothrombin *G20210A* mutation, protein C, protein S, AT deficiency, and APS if any of the following are present: <50 yr of age at first episode of thrombosis + strong family history of thrombosis or female family member of childbearing age, thrombosis in unusual anatomic location (cerebral veins or splanchnic veins; if splanchnic veins, consider testing as well for myeloproliferative neoplasms [MPN] and paroxysmal nocturnal hemoglobinuria [PNH]).
  2. Screen all others for APS.
- Arterial thrombosis: Screen for APS.
- NOTE: Routine screening for factor VIII level or hyperhomocysteinemia is not recommended.

BOX 1 Routine Investigations to Evaluate a Patient with Thrombosis

Test	Abnormality	Diagnostic Information
Complete blood count	Elevated hematocrit Increased white count Increased platelet count Leukopenia Thrombocytopenia	Myeloproliferative disorder (e.g., essential thrombocythemia, polycythemia vera); may be found in paroxysmal nocturnal hemoglobinuria; if associated with heparin administration, consider heparin-induced thrombocytopenia
Blood film	Leukoerythroblastic changes	Underlying neoplasm invading bone marrow
Liver function tests	Abnormal tests	May point to malignancy
Renal function	Impaired renal function	Assess prior to anticoagulation with heparin, low-molecular-weight heparin or new oral anticoagulants
Urinalysis	Proteinuria	Nephrotic syndrome; may be associated with venous thromboembolism or renal vein thrombosis
PT and aPTT	Prolonged PT and aPTT	To enable safe anticoagulation to proceed if required Need to exclude lupus anticoagulant

aPTT, Activated partial thromboplastin time; *PT,* prothrombin time.
Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

BOX 2 When to Perform a Thrombophilia Screen

Clinical Scenario
- First episode of unprovoked venous thromboembolism in individuals younger than 40 yr of age
- Thrombosis in an unusual site (e.g., cerebral or mesenteric thrombosis)
- Two or more first-degree relatives with unprovoked thrombosis
- Three or more early pregnancy losses, or one or more fetal deaths after 10 wk gestation

Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

BOX 3 Essential Tests for Thrombophilia Screening

- Basic coagulation screen
  1. International normalized ratio (INR): To exclude warfarin effect—warfarin will lower protein C and S levels
  2. Activated partial thromboplastin time (aPTT): To exclude heparin effect—heparin will lower antithrombin levels
- Functional assay for antithrombin (with heparin to detect type II defects)
- Functional assay for protein C
- Functional assay for protein S (immune assays for total and free protein S)
- APC resistance assay: With genetic test for factor V Leiden for confirmation of abnormal results
- Genetic test for *FIIG 20210A* gene mutation
- Anticardiolipin and β_2 -glycoprotein-1 antibodies (IgG and IgM) and lupus anticoagulant assay

APC, Activated protein C; *Ig,* immunoglobulin.
Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TIMING OF WORKUP:
- Ideally >3 wk after discontinuation of vitamin K antagonists (VKA) and >2 days after discontinuation of direct oral anticoagulant (DOAC) (except for APS, which requires prolonged anticoagulation).
- NOTE: Acute thrombosis, anticoagulation, pregnancy, and many medical conditions can affect the results and must be considered in the timing and interpretation of the workup.

LABORATORY TESTS
- CBC with peripheral smear, electrolytes, calcium, creatinine, blood urea nitrogen (BUN) and liver function tests, prothrombin time/partial thromboplastin time, prostate-specific antigen (in men aged >50 yr), urinalysis.
- Note: Genetic counseling and written informed consent should be obtained before genetic testing. Abnormal nongenetic tests should be repeated after 6 wk to decrease false-positive results.
- APCR: APC-resistance assay (using factor V–deficient plasma). Presence of lupus anticoagulant causes false positives. Follow-up positive APCR assay with genetic test for FVL.
- Prothrombin G20210A mutation testing.
- AT, protein C, and protein S deficiency: Functional assays; if decreased perform antigenic assay to determine type of deficiency. Antigenic assays for protein S should measure free and total levels. In protein C and protein S deficiency, the functional assay may be falsely low in the presence of APCR or elevated factor VIII level and falsely high if lupus anticoagulant is present.
- APS: Any one of the following found on two occasions at least 12 wk apart: Lupus anticoagulant, anticardiolipin antibodies, or anti–B_2-glycoprotein-I antibodies.

IMAGING STUDIES
Chest radiograph and other tests as appropriate to diagnose thrombosis and rule out associated conditions

Rx TREATMENT

NONPHARMACOLOGIC THERAPY
OC/HRT use and smoking should be avoided.

PROPHYLAXIS
- Prophylactic anticoagulation in high-risk situations.
- Patients with AT deficiency may benefit from antithrombin concentrates in high-risk situations.
- Pregnancy prophylaxis: Timing and intensity of therapy is based on the patient's risk (genetic or acquired defect and clinical history). Women with thrombophilia and recurrent adverse pregnancy outcomes may benefit from prophylaxis with heparin (low-molecular-weight heparin most commonly used) and low-dose aspirin.

ACUTE GENERAL Rx
Initial therapy is the same as for individuals with and without thrombophilia, with exceptions for protein C, AT, and APS deficiency as detailed in the following.

Venous thrombosis:
- DOACs such as Xa inhibitors (rivaroxaban and apixaban) have been FDA-approved for treatment in acute DVT and are currently recommended as first-line therapy. They have been found to be noninferior to warfarin, appear easier to use with fewer drug interactions, and have a trend toward less major bleeding.
- In patients unable to take DOACs, begin low-molecular-weight heparin (LMWH) and warfarin simultaneously. Continue heparin for at least 5 days and until international normalized ratio (INR) is therapeutic for 2 consecutive days; continue warfarin for at least 3 mo. Aim for INR of 2 to 3. Unfractionated heparin (UH) or fondaparinux (factor Xa inhibitor) may be used as alternatives to LMWH. LMWH is preferred over UH (except in patients with massive pulmonary embolism, increased risk of bleeding, or renal failure) because of equivalent or superior effectiveness and a better safety profile.
- Thrombophilia is not associated with a higher risk of recurrent VTE during warfarin therapy, with the exception of cancer patients in whom LMWH for 3 to 6 mo is associated with lower rates of recurrence than warfarin therapy.
- In pregnancy, anticoagulate with heparin throughout pregnancy and for at least 6 wk postpartum. Minimum duration of anticoagulation should be 6 mo. LMWH is preferred over UH. Warfarin may be used postpartum.
- Consider thrombolysis or thrombectomy in patients with massive pulmonary embolism or large proximal lower extremity DVT.

Protein C deficiency:
- Warfarin-induced skin necrosis: Discontinue warfarin, give vitamin K, and start heparin anticoagulation. Consider protein C replacement with protein C concentrate or fresh frozen plasma. Warfarin may be restarted at a low dose (2 mg daily for 3 days and increase by 2 to 3 mg daily until target INR is reached). Continue heparin for at least 5 days and until warfarin-induced anticoagulation is achieved.

AT deficiency:
- AT concentrates may be used if difficulty achieving anticoagulation (heparin resistance), severe thrombosis, or recurrent thrombosis despite adequate anticoagulation.

APS:
- Warfarin is superior to rivaroxaban in patients with APS. The RAPS trial randomized patients with APS to receive either rivaroxaban or warfarin and found significantly higher rates of thrombosis in the rivaroxaban group. A subsequent trial noted increased endogenous thrombin potential (a marker of less effective anticoagulation) in APS patients switched to rivaroxaban following initial VKA therapy compared to those continued on warfarin. This studied was not powered to assess clinical efficacy.

Arterial thrombosis:
- Anticoagulation and evaluation for thrombolysis or surgery

CHRONIC Rx
- Optimal duration of anticoagulation remains unknown. Length of therapy may be individualized by assessing the risk of recurrence. Residual thrombosis (on ultrasonography) or elevated D-dimer levels after completion of anticoagulation are associated with an increased risk of recurrence. With these findings, consider prolonging anticoagulation.

TABLE 8 Management of Women with a History of Venous Thrombosis during Pregnancy and the Puerperium

Clinical History	Thrombophilia	Antepartum	Postpartum[a]
Prior VTE due to a transient risk factor	No	Surveillance	Yes
Prior VTE due to pregnancy or estrogens	Yes or no	Prophylactic LMWH	Yes
Prior idiopathic VTE	Yes or no	Prophylactic LMWH	Yes
Recurrent VTE	Yes or no	Treatment dose LMWH	Resume long-term anticoagulation
No prior VTE Positive family history	Antithrombin deficiency; homozygous FII G20210A; or Factor V Leiden; or dual heterozygosity for both mutations	Prophylactic or intermediate dose LMWH	Yes

LMWH, Low-molecular-weight heparin; *VTE,* venous thromboembolism.
[a]Postpartum prophylaxis involves a 6-wk course of prophylactic doses of LMWH or dose-adjusted warfarin (target INR: 2.0 to 3.0).
Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

- Must consider risk and benefit; risk of major bleeding 2% to 3% annually in general population on anticoagulation but higher in the elderly (7% to 9% per yr). Long-term anticoagulation is usually not indicated given the low risk of recurrent thrombosis for most conditions and the bleeding risk associated with anticoagulation.
- Indefinite anticoagulation considered if any of the following:
  1. Life-threatening thrombosis or thrombosis at an unusual site
  2. More than a single genetic defect
  3. Presence of AT deficiency or APS
  4. Unprovoked DVT or PE with low bleeding risk
  5. >1 Provoked DVT or PE with low bleeding risk
- Patients with active cancer may benefit from indefinite anticoagulation.

DISPOSITION

Depends on underlying condition

REFERRAL

Hematology, maternal-fetal medicine, obstetric medicine

PEARLS & CONSIDERATIONS

COMMENTS

- Women with thrombophilic defects but no prior history of venous thromboembolism, or family history of the same, likely do not require antepartum prophylaxis or postpartum treatment, but definitive data are lacking. A summary of these recommendations is provided in Table 8.
- DOACs and warfarin therapy effectively reduce the risk of recurrent VTE; when therapy is discontinued VTE risk increases.
- Rivaroxaban is inferior to warfarin in patients with APS.
- Previous episode of VTE is a major risk factor for recurrence regardless of the presence of thrombophilia. Risk is greatest in the first 2 yr after thrombosis. 20% of all patients with unprovoked VTE have recurrence within 5 yr.
- Genetic risk factors for thrombosis in nonwhites remain largely unknown.
- Interpreting workup: Many medical conditions cause acquired abnormalities.
  1. Acute thrombosis may be associated with lupus anticoagulant, increased anticardiolipin antibodies, and elevated factor VIII levels
  2. Heparin therapy: Antithrombin levels decrease by up to 30%; can affect lupus anticoagulant testing
     a. Warfarin therapy: Cannot measure protein C and protein S (levels and function decrease); antithrombin levels may increase; can affect lupus anticoagulant testing
  3. Protein C, protein S, and antithrombin levels decrease with acute thrombosis (<2 wk), surgery, liver disease, disseminated intravascular coagulation, and chemotherapy. Protein C level also decreases with severe infection but levels increase with age and hyperlipidemia. Protein S and antithrombin levels also decrease with nephrotic syndrome, pregnancy, and estrogen therapy (HRT, OCs)
  4. APCR is increased with pregnancy, estrogen therapy (HRT, OCs), and certain cancers; elevated factor VIII level and antiphospholipid antibodies can cause APCR

PREVENTION

Risk of postthrombotic syndrome decreases if compression stockings are worn for at least 1 yr, starting in the first month after the DVT.

Hyperemesis Gravidarum PTG

BASIC INFORMATION

DEFINITION

Hyperemesis gravidarum refers to a severe and persistent form of nausea and vomiting in pregnancy. While no precise criteria exist to define the severity, it may be characterized by at least a 5% weight loss from prepregnancy weight, dehydration, ketonuria, and electrolyte imbalance. Typical onset occurs at wk 4 to 8 of pregnancy, continuing through wk 14 to 16 of pregnancy.

ICD-10CM CODES

O21.0 Mild hyperemesis gravidarum
O21.1 Hyperemesis gravidarum with metabolic disturbance

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 0.5% to 2% of pregnancies
GENETICS: A genetic predisposition may exist; hyperemesis gravidarum is more common among first-degree relatives of those diagnosed with the condition.
RISK FACTORS: Women with increased placental mass, including molar pregnancy or multiple gestation, family history or personal history of hyperemesis gravidarum, prior miscarriage, nulliparity, young age, hyperthyroidism, gastrointestinal disorders, vestibular disease, motion sickness, long interpregnancy interval, and supertaster status. Alcohol use, smoking, and anosmia may be protective. A female fetus increases the risk by 1.27-fold.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Weight loss of more than 5% from pre-gravid weight
- Symptoms: Nausea, vomiting, spitting, enhanced olfactory senses, food and/or fluid intolerance, lethargy
- Signs: Poor skin turgor, dry mucous membranes, hypotension, tachycardia
- Complications include inadequate caloric and nutritional intake, dehydration, and electrolyte abnormalities, including hyponatremia, hypocalcemia, hypokalemia, and, in severe cases, hypochloremic metabolic acidosis or Wernicke encephalopathy from thiamine deficiency. Severe hyperemesis gravidarum also has been shown to correlate with higher rates of anxiety and depression

ETIOLOGY

Unknown, but likely multifactorial. Theories include interactions between hCG and the thyroid, gestational hyperestrogenemia, and gastric dysrhythmias.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Gastrointestinal conditions: Gastroenteritis, gastroparesis, biliary tract disease, hepatitis, intestinal obstruction, peptic ulcer disease, appendicitis, inflammatory bowel disease
- Genitourinary tract conditions: Pyelonephritis, nephrolithiasis
- Metabolic disease: Hyperthyroidism, hyperparathyroidism, diabetic ketoacidosis, cannabinoid hyperemesis syndrome, porphyria, adrenal insufficiency
- Neurologic conditions: Pseudotumor cerebri, vestibular lesions, migraines, tumors of the central nervous system, cyclic vomiting syndrome
- Miscellaneous: Drug toxicity or intolerance, psychogenic
- Pregnancy-related conditions: Acute fatty liver of pregnancy, preeclampsia

WORKUP

Diagnosis is one of exclusion. History and physical examination along with laboratory tests to rule out other causes of vomiting should be performed.

LABORATORY TESTS

- BMP may reveal hyponatremia, hypokalemia, low serum urea.
- Urinalysis may show elevated specific gravity, ketonuria, or proteinuria.
- Liver enzymes (ALT typically more elevated than AST, both usually reaching only two to three times the upper limit of normal).
- Serum bilirubin (<4 mg/dl).
- Serum amylase or lipase (up to 5× greater than normal).
- CBC may show an increase in hematocrit from volume depletion.
- Magnesium and calcium may be low.
- TSH and free T4 (transient hyperthyroidism occurs in 2/3 of women with hyperemesis gravidarum; this is biochemical hyperthyroidism that usually resolves by 18 wk of gestation; testing and treatment should not be undertaken without additional clinical evidence of intrinsic thyroid disease).

IMAGING STUDIES

- Ultrasound to evaluate for multiple gestation or molar pregnancy
- If the patient is having associated pain, a right upper quadrant ultrasound may be indicated to evaluate biliary tract disease

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoidance of foods and smells that trigger nausea
- Ginger (200 to 500 mg q8h)
- Protein-heavy meals
- Reassurance and support, in some cases intensive cognitive-behavioral therapy

ACUTE GENERAL Rx

- Pyridoxine (vitamin B_6) 10 to 25 mg PO q8h
- Doxylamine 12.5 to 25 mg qhs
- Pyridoxine (10 mg)/doxylamine (10 mg) combination, starting with 2 tablets qhs and adding an additional 1 tablet q A.M. and 1 tablet q P.M. if needed
- Antiemetics including promethazine, prochlorperazine, metoclopramide, and ondansetron have been shown to be generally safe and effective in improving pregnancy outcome
- Corticosteroids (methylprednisolone, prednisone) may be considered after 10 wk of gestation
- IV fluid and electrolyte administration if evidence of deficiency is found
- Thiamine prior to dextrose administration to avoid Wernicke encephalopathy
- Restart oral intake gradually no less than 48 hr after vomiting has stopped

CHRONIC Rx

- If unable to tolerate oral intake, consider replacing with enteral or parenteral feeding
- Repeated IV fluid and electrolyte replacement can be conducted through outpatient visits

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Supportive psychotherapy
- Acupuncture
- Acupressure with use of a wrist band

DISPOSITION

- Infants born from pregnancies complicated by hyperemesis may have a higher risk of being small for gestational age or low birth weight than those not; however, this may be limited to infants of women who have experienced significant weight loss in the setting of hyperemesis.
- Women with hyperemesis gravidarum should be counseled that they have a higher risk than other women of developing similar symptoms in future pregnancies.

PEARLS & CONSIDERATIONS

COMMENTS

Nausea and vomiting in early pregnancy are associated with psychosocial morbidity.

RELATED CONTENT

Hyperemesis Gravidarum (Patient Information)

AUTHORS: **T. Caroline Bank, MD,** and **Anthony Sciscione, DO**

BASIC INFORMATION

DEFINITION

Hypereosinophilic syndrome (HES) refers to overproduction of eosinophils with sustained eosinophil counts over 1500/ml (1.5×10^9/L), in which eosinophilic infiltration of tissues (skin, lungs, heart, liver, spleen, lymph nodes) and mediator release cause organ dysfunction. HES may be primary or have a reactive cause.

SYNONYMS

Idiopathic hypereosinophilic syndrome (IHES)
HES

ICD-10CM CODE
D72.1 Eosinophilia

EPIDEMIOLOGY & DEMOGRAPHICS

PREDOMINANT SEX: Occurs in men more often than women (9:1)
PREDOMINANT AGE: Usually occurs between the ages of 20 and 50 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Clinical presentation of HES may vary from an incidental finding of eosinophilia to sudden onset of cardiac or neurologic symptoms.
- Early presentation includes fatigue, cough, breathlessness, muscle pain, angioedema, rash, and fever.
- Cardiac manifestations (58%) include dyspnea, orthopnea, and signs and symptoms of congestive heart failure (CHF). Includes three stages: Acute necrotic stage secondary to endocardial infiltration of eosinophils, thrombus formation, and fibrotic stage. This may result in a restrictive or dilated cardiomyopathy and/or valvular heart disease.
- Neurologic manifestations (54%) may be of three types:
  1. Thromboembolic (e.g., cardiac emboli or local vascular thrombosis)
  2. CNS dysfunction: Confusion, loss of memory, ataxia, upper motor neuron signs, seizures, and behavior changes
  3. Peripheral neuropathy (most common) may be symmetric or asymmetric, sensory or mixed sensory, and motor deficits
- Pulmonary manifestations (40%) include a chronic persistent nonproductive cough, shortness of breath, and dyspnea on exertion. Diffuse or focal infiltrate may present in 20% of cases. Complications may include pulmonary fibrosis, CHF, or pulmonary embolus.
- Cutaneous manifestations (56%) usually include eczema, lichenifications, urticaria, angioedema, or erythematous pruritic papules and nodules.
- GI manifestations (23%) include diarrhea, but findings of gastritis, colitis, pancreatitis, cholangitis, and hepatitis can occur.
- Ocular manifestations (23%) are thought to be the result of retinal microemboli.
- Vascular manifestations include venous or arterial thrombosis of unknown mechanism such as femoral artery occlusion, intracranial sinus thrombosis, and digital gangrene.

ETIOLOGY

- Primary HES is a myeloproliferative neoplasm (MPN) with molecular activation of platelet-derived growth factor receptor (PDGER). Secondary (reactive) HES occurs in response to an identified stimulus (see "Differential Diagnosis").
- In some cases, a fusion event generating an abnormal and oncogenic tyrosine kinase (FIP1L1-PDGFRA) appears to be causative, especially in males.

DIAGNOSIS

Criteria for the diagnosis of idiopathic HES include:

- Persistent eosinophilia of >1500 eosinophils/mm^3 for more than 6 mo
- Exclusion of other conditions causing eosinophilia (Box E1)
- Signs and symptoms of organ system dysfunction (e.g., heart, liver, lung)

DIFFERENTIAL DIAGNOSIS

The differential diagnosis includes all causes of peripheral blood eosinophilia: Parasitic infections, coccidioidomycosis, cat-scratch disease, asthma, Churg-Strauss syndrome, allergic rhinitis, atopic dermatitis, drug-induced eosinophilia, aspergillosis, eosinophilic pneumonia, hypersensitivity pneumonitis, HIV, eosinophilic gastroenteritis, inflammatory bowel disease, leukemias (CML and CMML), and systemic mastocytosis with eosinophilia.

WORKUP

The workup of a patient who is suspected of having HES should exclude other causes mentioned in the "Differential Diagnosis" section leading to peripheral eosinophilia.

LABORATORY TESTS

- CBC with differential; often the total WBC ranges from 10,000 to 30,000/mm^3 with eosinophilia of 30% to 70%, anemia is present in 50% of the cases, and either thrombocytopenia or thrombocytosis may be noted
- Erythrocyte sedimentation rate (ESR) and rheumatoid factor
- Liver function tests (LFTs), electrolytes, urinalysis, BUN, and creatinine
- HIV assay
- Stools for ova and parasites ×3
- Serologic blood tests for parasitic infections (e.g., *Strongyloides*)
- Total IgE level
- Bone marrow aspirate and biopsy (Fig. E1)
- Duodenal aspirate
- ECG
- Tissue biopsies as indicated
- Serum levels of vitamin B_{12}
- Serum levels of tryptase

IMAGING STUDIES

- Chest radiograph may be clear or show infiltrates, effusions, or fibrotic scarring.
- CT scan of chest, abdomen, and pelvis.
- Echocardiogram (or cardiac MRI for early cardiac involvement) can assess for ventricular function and valvular pathology including regurgitation and thrombi formation.

TREATMENT

Treatment is initiated only if there is evidence of organ involvement. In primary (neoplastic) HES, treatment of underlying disorders can improve eosinophilia.

NONPHARMACOLOGIC THERAPY

In patients with hypereosinophilia without organ involvement, serial echocardiograms, blood chemistries, and pulmonary function tests are recommended at 6-mo intervals.

ACUTE GENERAL Rx

- In patients with organ involvement without FIP1L1-PDGFRA fusion, initial therapy is with prednisone 1 mg/kg/day or 60 mg/day in adults.
- Patient's symptoms and peripheral eosinophil counts are monitored.
- Doses may be tapered to alternate-day prednisone use in patients whose eosinophil counts have been suppressed.

CHRONIC Rx

- Steroid-refractory patients with FIP1L1-PDGFRA fusion can be treated with imatinib.
- If the disease continues to progress, vincristine, etoposide, interferon-α, cyclosporine, and leukapheresis are alternative choices.
- Anticoagulation and/or antiplatelet agents are often used in patients with HES.
- If all else fails, bone marrow transplantation may be considered.

DISPOSITION

- Before the use of cardiac imaging (echo) and cardiac surgeries (valve replacement), patients with HES had a poor prognosis with a mean survival time of 9 mo and a 3-yr survival rate of 12%.
- Deaths usually result from CHF, endocarditis, and systemic emboli.
- 5-yr and 15-yr survival rates are 80% and 42%, respectively.

REFERRAL

HES is a rare and complicated disorder requiring a multidisciplinary approach.

AUTHOR: **Fred F. Ferri, MD**

BOX E1 Diseases, Syndromes, and Conditions Commonly Associated with Peripheral Blood Eosinophilia or Tissue Eosinophilia

Infectious Agents

Parasitic

- Tropical eosinophilia
- Visceral larval migrans (VLM, toxocariasis)
- Helminth infections
- Filariasis *(Wuchereria bancrofti, Brugia malayi)*
- Onchocerciasis
- Schistosomiasis
- Fascioliasis
- Paragonimiasis
- Strongyloidiasis
- Trichinosis
- Hookworm
- Ascariasis
- Echinococcosis/hydatid disease

Nonparasitic

- Coccidioidomycosis
- Chlamydial pneumonia of infancy
- Scarlet fever and pneumococcal pneumonia (convalescent phase)
- Cat-scratch disease
- Cryptococcosis (CSF eosinophilia) in HIV

Allergic Diseases

- Asthma (atopic and intrinsic, nasal polyps, aspirin intolerance syndromes)
- Bronchopulmonary aspergillosis
- Allergic rhinitis
- Urticarias (acute allergic and chronic idiopathic)
- Atopic dermatitis
- Acute drug (hypersensitivity) reactions (interstitial nephritis, cholestatic hepatitis, exfoliative dermatitis)

Respiratory Tract Disorders

- Hypersensitivity pneumonitis (rare)
- Allergic bronchopulmonary aspergillosis
- Eosinophilic pneumonia
- Transient pulmonary infiltrates (Löffler syndrome)
- Prolonged pulmonary infiltrates with eosinophilia (PIE syndromes)
- Tropical pulmonary eosinophilia (TPE)
- Bronchiectasis
- Cystic fibrosis

Endocrinologic Disorders

- Addison disease

Gastrointestinal Diseases

- Inflammatory bowel disease (IBD)
- Eosinophilic gastroenteritis, eosinophilic esophagitis (EE)
- Allergic gastroenteritis (young children)
- Celiac disease (when associated with EE)

Toxic Reactions to Ingested Agents

- Eosinophil myalgia syndrome (L-tryptophan)
- Toxic oil syndrome

Reactions to Cytokine Therapies

- IL-2 and IL-2 plus lymphokine-activated killer (LAK) cells
- GM-CSF for chemotherapy-induced neutropenia

Cutaneous Disorders

- Atopic dermatitis
- Immunologic skin diseases
- Scabies
- Eosinophilic cellulitis (Wells syndrome)
- Episodic angioedema with eosinophilia
- Chronic idiopathic urticaria
- Bullous pemphigoid
- Herpes gestationis

Immunodeficiency Syndromes

- Wiskott-Aldrich syndrome
- Selective IgA deficiency with atopy
- Hyper-IgE recurrent infection syndrome (Job syndrome)
- Swiss-type and sex-linked combined immunodeficiency
- Nezelof syndrome
- Graft-versus-host disease (GVHD)

Connective Tissue Diseases

- Vasculitis or collagen vascular disorders
- Hypersensitivity vasculitis
- Allergic granulomatosis with angiitis (Churg-Strauss syndrome)
- Serum sickness
- Eosinophilic fasciitis
- Sjögren syndrome
- Rheumatoid arthritis (severe)

Neoplastic and Myeloproliferative Diseases and Syndromes

- Ovarian carcinoma
- Solid tumors (mucin secreting, epithelial cell origin)
- Eosinophilic leukemia
- Idiopathic hypereosinophilic syndrome (HES)
- Systemic mastocytosis
- Lymphomas (T cell, Hodgkin)
- Chronic myelogenous leukemia, acute myelogenous leukemia, MDS (myelodysplastic syndrome)
- T-cell lymphocytic leukemia
- Myelomonocytic leukemia with bone marrow eosinophilia (M4Eo, inversion 16)
- Angioimmunoblastic lymphadenopathy
- Angioblastic lymphoid hyperplasia (Kimura disease)

Rare Causes

- Chronic active hepatitis
- Chronic dialysis
- Acute pancreatitis
- Postirradiation
- Hypopituitarism

CSF, Cerebrospinal fluid; *GM-CSF,* granulocyte-macrophage colony-stimulating factor; *HIV,* human immunodeficiency virus; *Ig,* immunoglobulin; *IL,* interleukin.

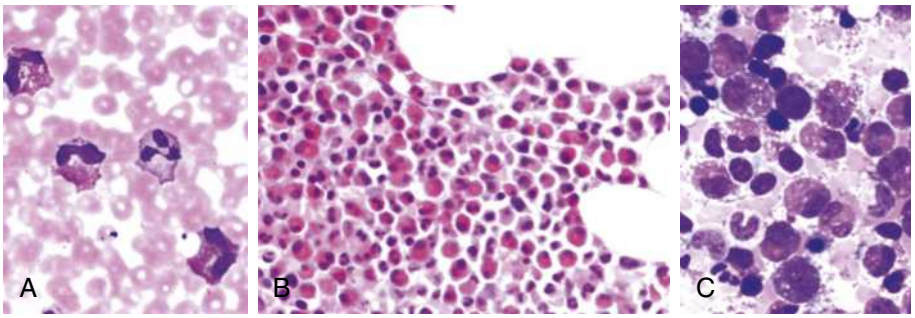

FIG. E1 Hypereosinophilic syndrome. The illustration is from the case of a 38-yr-old woman who was found to have a marked eosinophilia when she presented with headaches, nausea, and vomiting. The white blood cell count was 16,900/μl, with 36% eosinophils **(A).** The bone marrow was hypercellular and showed sheets of eosinophils **(B).** On the aspirated material **(C),** eosinophils and eosinophilic precursors accounted for more than 70% of the cells. The patient had no obvious infectious process and no allergies. There was no malignancy associated with eosinophilia, such as T-cell lymphoma, Hodgkin lymphoma, or other myeloid disease. Peripheral blood lymphocyte phenotyping showed no abnormal T-cell subset. Cytogenetic analysis showed a normal female karyocyte, and fluorescence in situ hybridization analysis for del 4q12 showed no deletion of CHIC2. (From Hoffman R et al: *Hematology: basic principles and practice,* ed 5, Philadelphia, 2009, Churchill Livingstone.)

BASIC INFORMATION

DEFINITION

Hyperglycemic hyperosmolar syndrome (HHS) is a life-threatening complication of diabetes mellitus characterized by marked hyperglycemia, dehydration, and hyperosmolality with or without mental obtundation, in the absence of significant ketoacidosis.

SYNONYMS

HHS
Hyperosmolar hyperglycemic syndrome
Diabetic hyperosmolar syndrome
Hyperglycemic hyperosmolar nonketotic syndrome
Hyperglycemic hyperosmolar nonketotic coma
Hyperosmolar hyperglycemic state
Nonketotic hyperosmolar syndrome

ICD-10CM CODES

E08.00	Diabetes mellitus due to underlying condition with hyperosmolarity without nonketotic hyperglycemic-hyperosmolar coma (NKHHC)
E08.01	Diabetes mellitus due to underlying condition with hyperosmolarity with coma
E09.00	Drug or chemical induced diabetes mellitus with hyperosmolarity without nonketotic hyperglycemic-hyperosmolar coma (NKHHC)
E09.01	Drug or chemical induced diabetes mellitus with hyperosmolarity with coma
E11.00	Type 2 diabetes mellitus with hyperosmolarity without nonketotic hyperglycemic-hyperosmolar coma (NKHHC)
E11.01	Type 2 diabetes mellitus with hyperosmolarity with coma
E13.00	Other specified diabetes mellitus with hyperosmolarity without nonketotic hyperglycemic-hyperosmolar coma (NKHHC)
E13.01	Other specified diabetes mellitus with hyperosmolarity with coma

EPIDEMIOLOGY & DEMOGRAPHICS

HHS is a rare condition that most commonly affects patients with type 2 diabetes mellitus. Approximately 20% of patients have no history of diabetes. Elderly individuals with new-onset diabetes or those with poorly controlled type 2 diabetes predisposed to extracellular fluid volume depletion (so-called dehydration) are at increased risk for HHS. Mortality from HHS is estimated at 5% to 20%, a greater mortality rate than for diabetic ketoacidosis.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Polyuria, polydipsia, weight loss, weakness
- Mental status changes that can range from full alertness to coma
- Focal neurologic signs (e.g., hemiplegia, hemianopsia) or seizures (focal or generalized), aphasia, visual hallucinations
- Symptoms of coexisting illnesses or comorbidities that may have precipitated the event
- Signs of extracellular fluid volume depletion, including dry mucous membranes, poor skin turgor, sunken eyes, hypotension, and tachycardia
- Normothermia or hypothermia despite the presence of infection, due to peripheral vasodilation

ETIOLOGY

HHS can be precipitated by various conditions:

- Infection (most common precipitant)
- Insulin deficiency (undiagnosed diabetes, inadequate insulin, or medication nonadherence)
- Inflammatory conditions (e.g., acute pancreatitis, acute cholecystitis)
- Ischemia/infarction (e.g., myocardial infarction, stroke, bowel ischemia)
- Kidney failure
- Severe dehydration (e.g., burns, heatstroke)
- Drugs (e.g., steroids, thiazides, atypical antipsychotics, sympathomimetics including cocaine, alcohol, pentamidine)

A relative insulin deficiency provides enough insulin to inhibit ketogenesis but is insufficient to inhibit hepatic gluconeogenesis, glycogenolysis, or peripheral glucose uptake, with consequent hyperglycemia. With underlying illness, counterregulatory hormone excess leads to further blood glucose elevation. The resultant extreme hyperglycemia leads to osmotic diuresis. If adequate hydration is not maintained, dehydration and worsening renal function ensue. Diminished renal filtration further impairs glucose excretion, thus exacerbating the hyperglycemia, dehydration, and hyperosmolality.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Diabetic ketoacidosis
- Stroke (especially in the elderly with neurologic abnormalities)
- Hypovolemic or septic shock
- Encephalopathy

WORKUP

After the initial history is obtained, perform a physical exam that includes immediate evaluation of airway, breathing, circulation, mental status, volume status, and signs suggestive of precipitating event including infection, myocardial infarction, or stroke.

LABORATORY TESTS

- Hyperglycemia: Blood glucose >600 mg/dl (Box 1)
- Serum osmolality: >320 mOsm/kg, typically
- Complete metabolic panel, including serum creatinine, blood urea nitrogen (BUN), electrolytes, glucose
- Serum sodium: May be low, normal, or high. Hyperglycemia increases plasma osmolality that translocates intracellular water to the extracellular compartment, decreasing serum sodium. Serum sodium can be corrected by adding 1.6 mmol/L to the measured serum sodium for each 100 mg/dl rise in serum glucose above 100 mg/dl. Marked osmotic diuresis induced by hyperglycemia may cause the serum sodium level to be normal or high
- Serum potassium and phosphate: Total body potassium and phosphate deficits typically occur due to urinary losses from osmotic diuresis. However, these levels may be acutely normal or high due to extracellular shift secondary to insulin deficiency and hyperosmolality
- Anion gap and serum lactate: Anion gap may be normal or elevated in the setting of lactic acidosis
- Arterial blood gas: pH >7.3
- Serum and urine ketones: Negative or small
- Serum bicarbonate: >15 mmol/L
- Hemoglobin A_{1c} (if not performed in past 3 mo)
- Complete blood count with differential (may indicate presence of underlying infection [leukocytosis >25,000 mm^3], inflammatory condition, hemoconcentration. A leukocytosis of 10,000 to 15,000 mm^3 is expected from the stress of illness alone)
- Urinalysis, urine/sputum/blood cultures as indicated based on physical exam findings to evaluate the precipitating illness and other comorbidities

IMAGING STUDIES

ECG, chest radiograph, and other imaging studies as indicated to evaluate the precipitating causes

BOX 1 Diagnostic Testing Criteria for Patients with Hyperglycemic Hyperosmolar State

Glucose higher than 600 mg/dl
Normal pH (classically, however, patients are often mildly acidotic)
No significant ketosis*
Serum osmolarity
- >320 mOsm/L with any mental status changes, *or*
- >350 mOsm/L

*Serum acetoacetate is often present, typically an absent or low β-hydroxybutyrate level.
From Adams JG et al (eds): *Emergency medicine: clinical essentials,* ed 2, Philadelphia, 2013, WB Saunders.

Rx TREATMENT

ACUTE GENERAL Rx Aggressive fluid resuscitation, intravenous insulin, and electrolyte correction are the mainstays of treatment. Patients with HHS are very ill, and many are elderly. Elderly patients may require slower correction of osmolality to limit cerebral edema.

AGGRESSIVE INTRAVENOUS FLUID REPLACEMENT: Due to trivial ketonemia and the insulin sensitivity of most HHS patients, initial treatment is intravenous fluid alone without insulin. Insulin used prior to intravenous hydration or early in resuscitation risks a precipitous drop in serum osmolality. In the absence of cardiac compromise or end-stage renal disease, infuse 0.9% normal saline (NS) at an initial rate of 1 L/h. A lower rate of 250 to 500 ml/hr may be adequate in the absence of severe dehydration. If the corrected serum sodium is elevated, 0.45% NS may be infused instead. Reassess corrected sodium needs by frequent checks and calculation. Recommended sodium decline is 0.5 mmol/L/hr and should not surpass 10 to 12 mmol/L per day. Use measured or calculated osmolality to guide the rate of fluid resuscitation for gradual normalization of osmolality. Once serum glucose decreases to 300 mg/dl, change the intravenous fluid to 5% dextrose with 0.45% NS at 150 to 250 ml/hr.

INSULIN: Once glucose is no longer significantly improving with fluids alone, reassess patient's fluid status and initiate intravenous insulin. Administer initial bolus of intravenous regular insulin 0.1 units/kg followed by 0.1 units/kg/hr infusion or a continuous infusion of 0.14 units/kg/hr without initial bolus. If serum glucose declines by less than 50 to 75 mg/dl in the first hour, increase the insulin infusion rate. Once the serum glucose reaches 300 mg/dl, decrease the insulin infusion rate to 0.02 to 0.05 units/kg/hr to maintain serum glucose between 200 to 300 mg/dl until resolution of HHS.

POTASSIUM REPLACEMENT: Insulin therapy shifts potassium intracellularly, frequently causing hypokalemia. If serum potassium at presentation is between 3.3 and 5.2 mmol/L, infuse 20 to 30 mmol of potassium chloride (KCl) with each liter of intravenous fluid to maintain serum potassium between 4 and 5 mmol/L. If the serum potassium concentration at presentation is <3.3 mmol/L, replace potassium by administering KCl infusion at 20 to 30 mmol/h, and withhold insulin until the serum potassium concentration is >3.3 mmol/L. If the serum potassium at presentation is >5.2 mmol/L, monitor serum potassium level every 2 hours without intravenous potassium supplementation.

PHOSPHORUS AND MAGNESIUM REPLACEMENT:

- Phosphorus and magnesium replacement are not routinely recommended. There are no studies of the utility of phosphate administration during treatment of HHS. Very low phosphorus levels may limit adenosine triphosphate (ATP) generation, thus limiting adequate diaphragm function. In patients with cardiac dysfunction, respiratory depression, or anemia and serum phosphate <1 mg/dl, add 20 to 30 mmol/L potassium phosphate to intravenous fluids.
- Monitor serum glucose hourly and serum electrolytes, BUN, and creatinine every 2 to 4 hours until resolution of HHS.

TRANSITION TO SUBCUTANEOUS INSULIN: Normalization of serum osmolality and mental status indicates resolution of HHS. At this point, a transition to subcutaneous insulin should be performed. Overlap the initiation of subcutaneous intermediate- or long-acting insulin and discontinuation of intravenous insulin by 2 to 4 hours to ensure adequate insulin levels and prevent rebound hyperglycemia. In patients with a known history of diabetes, their home insulin regimen may be initiated if adequate prior to presentation. In patients with poorly controlled diabetes, the subcutaneous insulin dose can be determined based on their stable insulin drip requirement. Insulin-naive patients may be started on basal-bolus insulin therapy either by calculation of total daily dose of 0.5 to 0.8 units/kg (split as half-basal and half-bolus; administer one-third total bolus for each meal) or by their individual stable insulin drip requirements. Further subcutaneous insulin dose titration is based on subsequent blood glucoses. Resolution of glucotoxicity and inciting condition(s) will decrease insulin requirements. The underlying infection/inflammatory condition or precipitating event must be adequately treated.

CHRONIC THERAPY: Most patients will need insulin at discharge, at least short term. Patients whose diabetes was previously well controlled on oral agents may resume oral therapy after blood glucose stabilization by insulin.

DISPOSITION Most patients require management in an emergency care setting, such as the intensive care unit or in a step-up facility.

PEARLS & CONSIDERATIONS

COMMENTS

- When patients with ESRD experience development of HHS, special management considerations are needed. Aggressive fluid resuscitation is unnecessary in anuric ESRD patients, because most patients cannot produce the osmotic diuresis associated with normal kidney function. Note that urinary potassium and phosphorus losses will not occur, thereby limiting the need for supplementation. Lower continuous insulin infusion rates are required in ESRD patients because of decreased insulin clearance. Hemodialysis is typically delayed until serum glucoses are corrected. Precipitous decreases in serum glucose from insulin administration and hemodialysis may result in rapid shifts in tonicity, predisposing cerebral edema.
- Education of the patient, family, and caregivers at chronic care facilities regarding optimal glycemic control, limiting modifiable risk factors for HHS, and prevention of dehydration is paramount.

AUTHORS: **Jessica E. Shill, MD,** and **Stanley Linder, DO**

BASIC INFORMATION

DEFINITION

- Hyperhidrosis is the excessive production of sweat beyond the body's physiologic need for thermoregulation.
- There are two types of hyperhidrosis: primary and secondary. Primary hyperhidrosis is the idiopathic, bilateral, and symmetric sweating from focal areas. Secondary hyperhidrosis is either generalized or focal excessive sweating due to an underlying cause (e.g., diet, medication, or medical condition).
- Primary hyperhidrosis affects many aspects of daily life, which can be detrimental to emotional well-being, self-esteem, interpersonal relationships, as well as work and productivity. Despite this, only one third of those affected consult a physician about their problem. Primary care physicians are essential in the initial diagnosis and treatment of this condition. Early detection and treatment can significantly improve a patient's quality of life, with treatment efficacy between 90% and 95%.

SYNONYM

Excessive perspiration

ICD-10CM CODES

L74.513 Primary hyperhidrosis
L74.52 Secondary focal hyperhidrosis

EPIDEMIOLOGY & DEMOGRAPHICS

According to recent epidemiologic data, hyperhidrosis affects approximately 4.8% of the U.S. population (15.3 million people), and prevalence in both genders is approximately equal. However, women are more likely to discuss the condition with their physician.

PEAK INCIDENCE: The average age of onset is 25 yr.

PREVALENCE: The condition is most common among people aged 25 to 64 yr.

PREDOMINANT SEX AND AGE: Equal proportions male and female.

GENETICS: Unknown.

RISK FACTORS: None known for primary, but secondary has numerous causes (see Table 1).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- History:
  1. Pattern of sweating: Frequency, stress exacerbation, volume, duration, body areas involved, symmetry, triggers, and presence or absence during sleep
  2. Impact on daily life
  3. Family history
  4. Medications that could induce sweating
  5. Excessive intake of coffee or other stimulants
  6. Review of systems to evaluate for systemic disease: Fever; weight loss; anorexia; palpitations; other signs of thyroid, malignant, or neurologic diseases
- Physical examination: Evidence of excessive sweating and location on patient's body

DIAGNOSIS

The initial diagnostic step is to evaluate whether the patient's symptoms represent primary or secondary hyperhidrosis.

- Primary: Greater than 90% of cases are primary. Criteria for diagnosis include focal and visible excessive sweating for greater than 6 months without any apparent cause, as well as at least two of the following:
  1. Impairment of daily activities
  2. Bilateral and symmetric sweating (axilla [most common], palms, soles, face, or scalp)
  3. Occurrence at least once per week
  4. Onset younger than 25 yr
  5. No abnormal nocturnal sweating
  6. Positive family history

  NOTE: If four criteria are met, the discrimination between primary and secondary increases (positive predictive value, 0.99; negative predictive value, 0.85)
- Secondary: Less than 10% of cases but with numerous underlying causes, which can be divided between focal and generalized sweating patterns.

Focal:

- Neurologic (neuropathy, spinal injury, Horner syndrome, Arnold-Chiari malformation)
- Gustatory sweating after eating spicy foods

Generalized:

- Medications (cholinergic agents, selective serotonin reuptake inhibitors/serotonin–norepinephrine reuptake inhibitors, selective estrogen receptor modulators, insulin, sulfonylureas, niacin, sildenafil, etc.)
- Toxicity (recreational drugs, alcohol, drug/alcohol withdrawal)
- Endocrine (hypoglycemia, hyperthyroidism, hyperpituitarism, pheochromocytoma, menopause, pregnancy, acromegaly)
- Neurologic (Parkinson disease, cerebrovascular accident)
- Malignancy (lymphoma, carcinoid)
- Psychiatric (panic attack, social anxiety, generalized anxiety disorder)
- Cardiopulmonary (acute respiratory failure, congestive heart failure, chronic obstructive pulmonary disease, myocardial infarction)
- Infection and fever
- Table 1 summarizes all causes of hyperhidrosis

Hyperhidrosis

DIFFERENTIAL DIAGNOSIS

- Primary hyperhidrosis
- Fever
- Anxiety disorder
- Heart attack
- Hyperthyroidism
- Hypoglycemia
- Malignancy
- Menopause
- Heat exposure
- Obesity

WORKUP

No further workup is necessary to diagnose primary hyperhidrosis; secondary hyperhidrosis will require more specific testing to evaluate the underlying cause.

LABORATORY TESTS

There are no specific laboratory tests for primary hyperhidrosis. Underlying causes of secondary hyperhidrosis might dictate further laboratory workup.

IMAGING STUDIES

None

Rx TREATMENT

- Primary hyperhidrosis:
  1. Topical:
     a. Aluminum chloride 20% to 25% (first line in mild cases) can produce mild localized burning at application sites.
     b. Glycopyrronium cloth (Qbrexza) is a premoistened cloth containing the long-acting anticholinergic agent glycopyrronium. It is applied once daily for the treatment of excessive underarm sweating (primary axillary hyperhydrosis). It is an expensive alternative first-line treatment useful in severe cases.
     c. Aldehyde agents (formaldehyde, glutaraldehyde) can cause allergic sensitization and localized skin irritation.
  2. Botulinum toxin A injection (first line in severe cases) is safe and effective but expensive; preferred option for axillary hyperhidrosis.
  3. Systemic treatments (oral anticholinergics, beta-blockers, clonazepam).
- Secondary hyperhidrosis:
  1. Diagnose and treat the underlying condition.

NONPHARMACOLOGIC THERAPY

- Electrical current (iontophoresis): Introduction of charged ions into skin to disrupt eccrine gland secretion
- Microwave therapy: Destroys eccrine glands through cellular thermolysis
- Surgery (endoscopic sympathectomy): Destruction of the sympathetic ganglia innervating areas of excessive sweating

DISPOSITION

Hyperhidrosis is a chronic medical condition that will need long-term treatment with either topical medications, oral medications, or surgical intervention. Discuss with the patient which treatment option is best for the patient.

REFERRAL

If initial treatments are ineffective, referral to a dermatologist can be considered.

BASIC INFORMATION

DEFINITION

Abnormal elevation of potassium (K^+) in the blood associated with either normal or altered total body stores of potassium. Normal K^+ level in the blood is 3.5 to 5.0 milliequivalents per liter (mEq/L). Hyperkalemia can be defined as mild (levels 5.1 to 6.0 mEq/L), moderate (levels 6.0 to 7.0 mEq/L), and severe (levels >7.0 mEq/L). Levels higher than 7 mEq/L can lead to significant hemodynamic and neurologic consequences, whereas levels exceeding 8.5 mEq/L can cause respiratory paralysis or cardiac arrest and quickly be fatal.

SYNONYM

High potassium

ICD-10CM CODE
E87.5 Hyperpotassemia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE & PREVALENCE:

- Overall incidence and prevalence of hyperkalemia is unknown. The rate is low in uncomplicated hypertensives on the inhibitors of renin-angiotensin-aldosterone system (RAASi), but it rises in the setting of other comorbidities listed below.
- Rarely detected in the general population, it is seen in only 2.6% of emergency room visits and 3.5% of hospital admissions in a Canadian study, with similar results in two U.S. studies.
- Chronic kidney disease (CKD) patients are most prevalent at 10%. Increased risk depends on the underlying conditions present. Is also seen with end-stage kidney disease (ESKD), acute kidney injury (AKI), cardiovascular disease (CVD), diabetes mellitus (DM), or metabolic acidosis (especially associated with non-gap inorganic acidosis), and on medications such as RAASi and mineralocorticoid receptor inhibitors (MRA) and other potassium-sparing diuretics.
- The prevalence of ICD-10 diagnosis for hyperkalemia was found to be very low (14.6%).

PREDOMINANT SEX & AGE:

- More common with increasing age due to increased prevalence of etiological factors such as CKD, DM, CVD, and concomitant use of medications that predispose to hyperkalemia.
- Lower socioeconomic groups also have an increased prevalence, where monitoring of drug therapy and control of DM and hypertension are often inadequate.

GENETICS: Other syndromes that may be associated with hyperkalemia include:

- Pseudohypoaldosteronism type II (familial hyperkalemic hypertension, also known as Gordon syndrome):
  1. Rare inherited form of hyperkalemia characterized by hypertension, hyperchloremic metabolic acidosis, and hyperkalemia with normal GFR.
  2. Mutations of several genes can be seen affecting sodium, potassium, and chloride transport in the tubule of the kidney.
  3. All forms respond to treatment with thiazide-like diuretics.
- Hyperkalemic periodic paralysis:
  1. Autosomal dominant mutation resulting in flaccid generalized weakness and hyperkalemia
- Glomerulopathy with fibronectin deposits (GFND):
  1. Autosomal dominant disorder manifested by proteinuria, hypertension, and type IV RTA
- Disorders of steroid metabolism and mineralocorticoid receptors:
  1. 21-hydroxylase deficiency and aldosterone synthase deficiency both associated with low aldosterone levels
- Congenital hypoaldosteronism:
  1. Autosomal recessive mutation associated with low aldosterone and salt wasting
  2. Increased serum ratio of 18-hydroxycorticosterone-to-aldosterone
- Nephronophthisis:
  1. Manifested by enlargement of kidneys, inflammatory portal fibrosis, and development of ESKD. Results in progressive interstitial fibrosis and tubulopathy.
- Disorders of chloride homeostasis:
  1. Autosomal recessive mutation causing isolated hyperchlorihidrosis with excessive salt wasting in sweat resulting in severe hyponatremic dehydration and hyperkalemia.

RISK FACTORS: Primary risk factor is CKD, especially if eGFR is <45 ml/min/1.73m^2 more commonly associated with diabetes mellitus type 1 or 2, or urinary tract obstruction with obstructive nephropathy (especially if associated with chronic interstitial nephritis).

Medications associated with hyperkalemia:

- Potassium-sparing diuretics (e.g., spironolactone, triamterene, amiloride, eplerenone)
- Nonsteroidal antiinflammatory drugs (NSAIDs)
- Angiotensin-converting enzyme inhibitors (ACEIs)
- Angiotensin receptor blockers (ARBs)
- Direct renin inhibitors
- Calcineurin inhibitors (cyclosporine and tacrolimus)
- Pentamidine
- Digoxin (toxicity especially in CKD)
- Trimethaphan-sulfamethoxazole
- Heparin
- Ketoconazole
- Metyrapone
- Herbs

Clinical risk factors:

- Male sex
- Non-black
- DM
- CVD
- CHF
- AKI
- CKD
- Acidosis (nonorganic)
- Urinary obstruction

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Most patients presenting with hyperkalemia are asymptomatic, with the abnormal laboratory study discovered inadvertently. The symptoms when present are nonspecific and mostly related to muscular or cardiac dysfunction.

- Muscle paralysis
- Dyspnea
- Palpitations
- Chest pain
- Nausea or vomiting
- Paresthesias

The physical exam typically does not alert the physician to a diagnosis of hyperkalemia, other than bradycardia, if present, or muscle tenderness accompanied by muscle weakness, suggesting rhabdomyolysis. Flaccid paralysis and/or depressed or absent deep tendon reflexes may be present.

ETIOLOGY

- Potassium is maintained in a narrow range of normal (3.8 to 5.0 mEq/L) by redundant and highly efficient homeostatic mechanisms that simultaneously control internal K^+ redistribution while regulating net K^+ excretion especially in the face of increased K^+. When a defect occurs in one or both of these two processes, a net rise in extracellular K^+ concentration occurs, resulting in hyperkalemia. We often see a blunting of the redistribution process with insulin deficiency, decrease in aldosterone production or action, decreased adrenergic activity, and osmolar disturbances associated with an increase in extracellular osmolality such as with hyperglycemia.
- The kidney is responsible for most of the regulation of potassium absorption and excretion (95%), which is dependent on the functional renal mass, thus the prominent association with CKD and reduced renal mass. Kidney failure or failure of the renal tubule to augment K^+ secretion plays a role in the maintenance of hyperkalemia. The importance of cell shifts is illustrated by the observation that if only 2% of potassium is shifted out of the cells to the extracellular fluid, it would raise the level from 4 mEq/L to 8 mEq/L, which would be critical.
- CKD is the single most important condition predisposing to hyperkalemia due to progressively decreasing GFR (falling clearance) and development of tubulointerstitial dysfunction (lower tubular secretion). Patients with progressive CKD are commonly associated with CVD, DM, HBP, and proteinuria, and they therefore are instructed to consume a diet very low in sodium, typically associated with a higher potassium intake. Low-sodium diets may be compensated for by an increase in salt-substitute intake, in many cases without the patients realizing that potassium chloride may further increase potassium intake. Another condition not uncommonly associated with CKD acutely increasing the risk of hyperkalemia is AKI, which, in addition to acutely reducing the capacity of the kidney to excrete a potassium load, can be associated

with an acute potassium load, especially if in the presence of tissue breakdown (e.g., rhabdomyolysis), gastrointestinal bleeding, or transfusions with outdated blood. Metabolic acidosis commonly acutely worsens in AKI, facilitating shift of potassium out of cells. These processes can often result in the development of severe and life-threatening hyperkalemia.

- DM (characterized by insulin deficiency and hypertonicity when uncontrolled, both of which shift potassium out of cells) and CVD (especially myocardial infarctions, left ventricular hypertrophy, and congestive heart failure, often associated with various pharmacologic interventions that may induce or worsen hyperkalemia). CVD often clusters with CKD and hence their concomitant presence may contribute to a higher prevalence of hyperkalemia. Among the relevant CVD medications, recall that β_2-2 receptor blockers inhibit renin production (decreasing ability of potassium to shift into cells); heparin inhibits aldosterone production (decreasing ability to excrete a potassium load); and digitalis impairs potassium excretion (by blocking Na-K-ATPase, which is important in potassium secretion by the tubule). The magnitude of impact on potassium by these medications, however, is limited, typically in the range of ~0.2 to 0.5 mEq/L. A much more relevant class is RAASi and potassium-sparing diuretics (Amiloride), with hyperkalemia seen in <2 % of patients without CKD, increasing to 5% with dual RAASi therapy, and up to 10% in the presence of CKD (especially stages >3b). In those patients at risk for hyperkalemia, it is recommended not to use dual RAASi therapy and to be very cautious with the use of RAASi and MRA.
- Congestive heart failure (CHF). Almost 4 out of 10 CHF patients in a population-based cohort study in Denmark developed hyperkalemia, many with recurrent episodes. Hyperkalemia risk was strongly associated with stage of CKD and use of spironolactone especially in addition to a renin-angiotensin system blocking medication.

TABLE 1 Differential Diagnosis of Hyperkalemia

- Pseudohyperkalemia
- Cellular redistribution from intra- to extracellular space
  1. Mineral acid acidosis (not endogenous organic acidosis)
     a. Hyperkalemia inhibits ammoniagenesis, reducing net acid secretion and compounding metabolic acidosis
  2. Hypertonicity (hyperglycemia, sucrose, mannitol)
  3. DM: Insulin deficiency
  4. Hyperkalemic periodic paralysis
  5. β2-adrenergic antagonists
  6. α-adrenergic agonists
  7. Drugs
     a. Glucagon
     b. Digoxin overdose
     c. Aminocaproic acid-A
     d. Tetrodotoxin
     e. Succinyl choline
  8. Rebound after labile
  9. Extreme exercise
  10. Crush and tissue injury
     a. Rhabdomyolysis
     b. Hemolysis
     c. Tumor lysis syndrome
- Decreased renal excretion
  1. CKD
     a. Use of nonsteroidal antiinflammatory drugs (NSAIDs)
  2. ESKD
  3. Type 4 renal tubular acidosis
     a. Diabetes mellitus
     b. Obstructive nephropathy
     c. Amiloride
     d. Trimethoprim
     e. Pentamidine
     f. Suxamethonium
     g. Volume depletion
     h. HIV infections
- Excess intake (rare except in advanced CKD or ESKD)
  1. Salt substitute (typically KCl)
  2. Potassium-enriched foods (melons, citrus juice, raw coconut juice has 44.3 mEq/L [44.3 mmol/L], noni juice has 56 mEq/L [56 mmol/L] K)
  3. River bed clay (red clay) very enriched, with 100 mEq K/100 g clay
- Mineralocorticoid deficiency (Addison disease)
  1. Hypoaldosteronism: Primary or secondary
  2. HIV infection
- Defect of tubular function or voltage defect resulting in hyperkalemia and hypertension:
  1. Genetic
     a. Pseudohyperaldosteronism type 2
- Also known as familial hyperkalemic hypertension or Gordon syndrome
  1. Acquired
     a. Calcineurin inhibitors (tacrolimus and cyclosporine)

CKD, Chronic kidney disease; *DM,* diabetes mellitus; *ESKD,* end-stage kidney disease; *KCl,* potassium chloride.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Hyperkalemia develops due to three mechanisms: redistribution, decreased secretion, and increased intake. (In the presence of normal renal and adrenal function, it is very difficult to ingest enough potassium to become hyperkalemic, so hyperkalemia is rarely seen in people without advanced CKD.) The differential diagnosis is listed in Table 1.

WORKUP

Fig. 1 illustrates a clinical approach to hyperkalemia. The following steps should be followed in the workup of hyperkalemia:

- R/O pseudohyperkalemia: An in vitro phenomenon caused by mechanical release of potassium from cells during phlebotomy or specimen processing. This may be seen with severe leukocytosis (>70,000/cm^3 or thrombocytosis (platelet count >500,000 cm^3), severe fist clenching during phlebotomy, prolonged application of a tight tourniquet, and use of a small-bore needle. The diagnosis is made when serum potassium concentration exceeds the plasma potassium concentration by >0.5 mEq/L (>0.5 mmol/L). Contamination with potassium EDTA in certain tubes can spuriously increase plasma potassium concentration accompanied by a very low plasma calcium concentration.
- If no predisposition to hyperkalemia, repeat the blood test before taking action, unless ECG changes are present.
- Perform an ECG to look for the hallmark changes seen with hyperkalemia, which commonly have a sequential progression that historically seemed to correlate with the potassium level, if present. Some studies seem to indicate inconsistent findings of the ECG in hyperkalemia, especially with K^+ levels <6.5 mEq/L and more predictive at levels >7.2 to 9.4 mEq/L.
  1. Early ECG changes seen with serum potassium level of 5.5 to 6.5 mEq/L: Peaked T waves (Fig. E2), especially in the precordial leads; shortened QT interval; and occasionally ST segment depression.
  2. K >6.5 mEq/L: Widening of the QRS complex (nonspecific intraventricular conduction delay [IVCD]) of >120 milliseconds that does not meet the criteria for right or left bundle branch block. If you see an IVCD, think hyperkalemia. May also see amplified R waves.

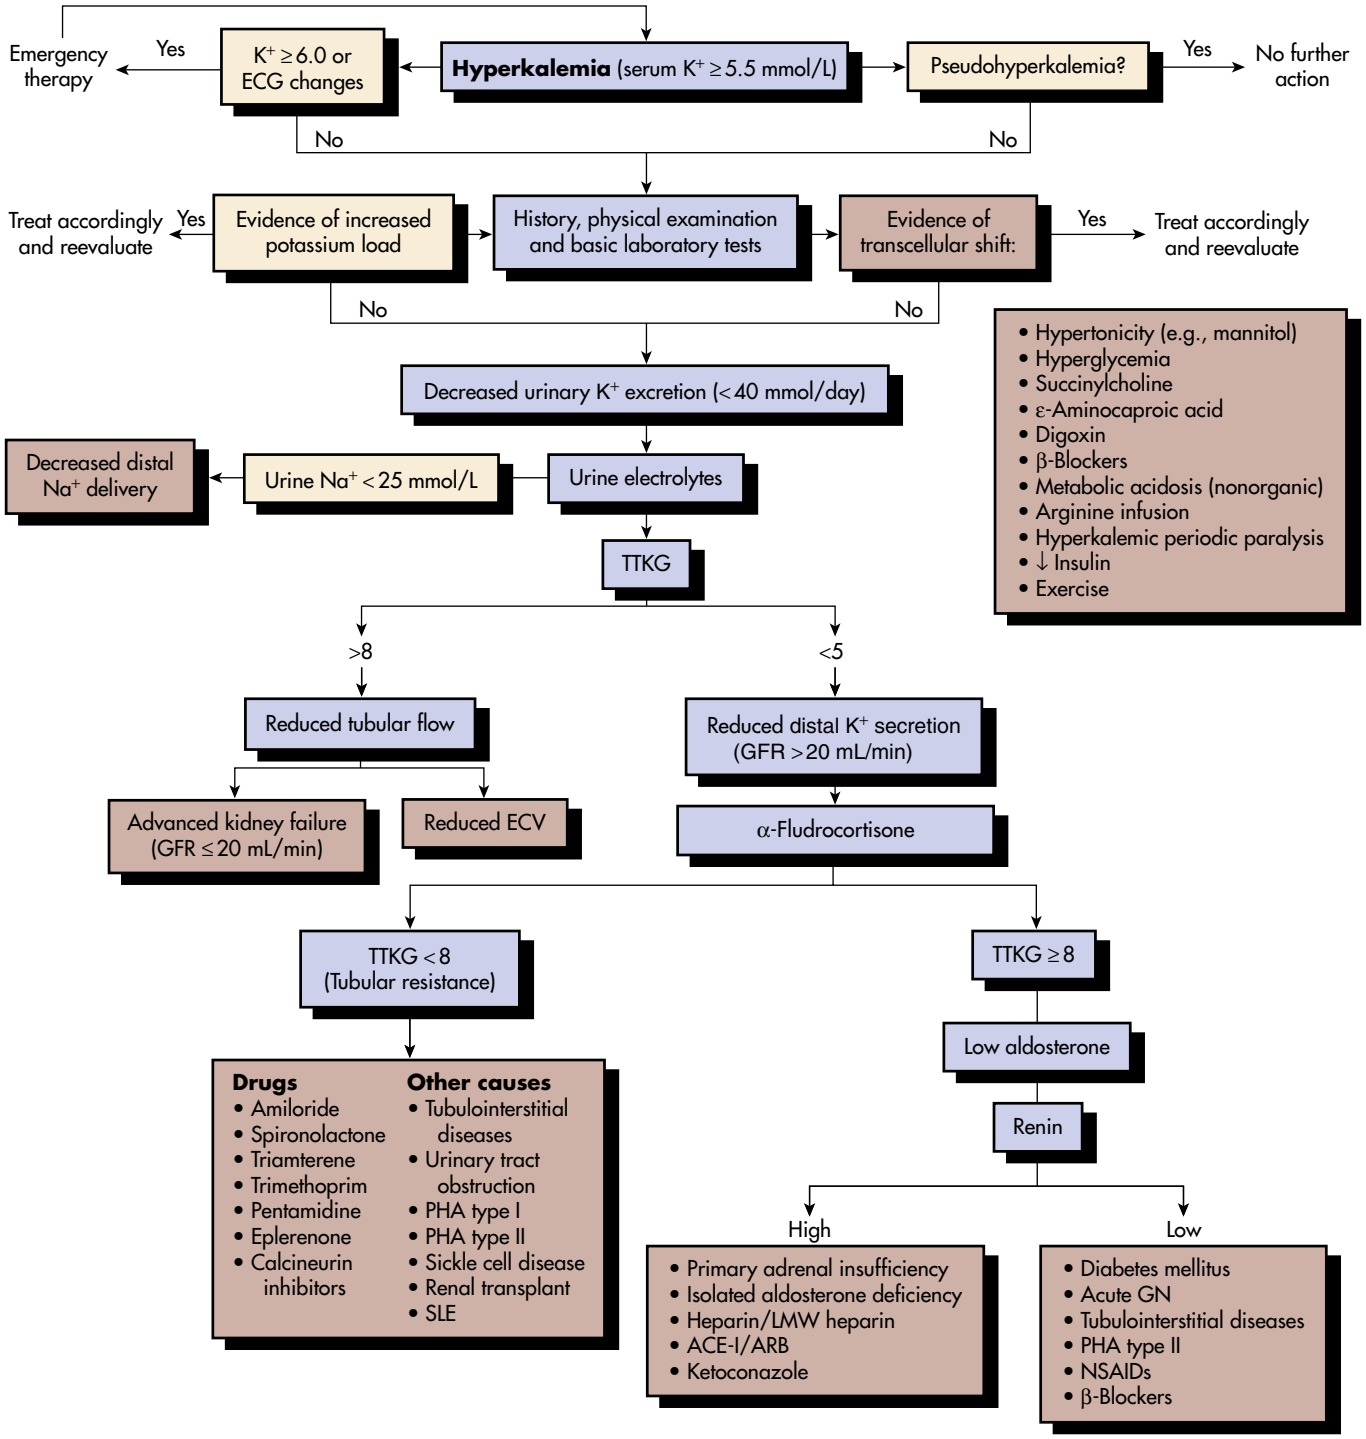

FIG. 1 Clinical approach to hyperkalemia. *ACE-I,* Angiotensin-converting enzyme inhibitor; *ARB,* angiotensin II receptor blocker; *CCD,* cortical collecting duct; *ECG,* electrocardiogram; *ECV,* effective circulatory volume; *GFR,* glomerular filtration rate; *GN,* glomerulonephritis; *HIV,* human immunodeficiency virus; *LMW heparin,* low-molecular-weight heparin; *NSAID,* nonsteroidal antiinflammatory drug; *PHA,* pseudohypoaldosteronism; *SLE,* systemic lupus erythematosus; *TTKG,* transtubular potassium gradient. (From Skorecki K et al: *Brenner & Rector's the kidney,* ed 10, Philadelphia, 2016, Elsevier.)

3. K >7 mEq/L: Associated with decreased amplitude of P waves with increase in PR interval and development of bradycardia, which is associated with atrioventricular blocks.
4. K >8.0 mEq/L: Develops absence of P waves and the progressively widened QRS eventually merges with the T waves, forming a sine wave pattern followed by ventricular fibrillation or asystole.

In hemodialysis patients with hyperkalemia, T wave "tenting" was nonpredictive of serum K^+ level, especially in the elderly and diabetics. There have even been case reports of severe hyperkalemia with no ECG changes.

- Look for the symptoms or physical findings noted above and then do the basic studies:
  1. ECG
  2. Urine potassium, sodium, and osmolality
  3. Complete blood count and platelet count
  4. Basic metabolic profile with a calculated estimated GFR (eGFR) (CKD alone should

not develop hyperkalemia until eGFR is <20 to 25 ml/min.)

5. Depending on the history and results of the initial blood tests, the following may be indicated:
   a. Glucose to r/o hypertonicity in uncontrolled diabetics
   b. Digoxin level if patient is on digoxin
   c. Arterial or venous blood gas if acidosis is suspected
   d. Urinalysis if renal insufficiency is present to r/o AKI or acute glomerulonephritis
   e. Serum cortisol and aldosterone levels to check for deficiency when other causes are eliminated
   f. Serum uric acid and phosphorus to r/o tumor lysis syndrome
   g. Serum creatinine phosphokinase (CPK) and calcium measurements for rhabdomyolysis
   h. Urine myoglobin test (if you see a very + dipstick of urine for blood and no RBCs, be suspicious of this) for crush injury and rhabdomyolysis

- Accurately assess kidney function with a serum creatinine and calculated GFR to define the risk of hyperkalemia as well as the acid base status, especially identifying the presence of a non-anion gap mineral metabolic acidosis.
- Look for the presence of a non-anion gap mineral metabolic acidosis associated with the hyperkalemia typically diagnosing a type 4 RTA. This is typically seen with a hyporeninemic hypoaldosterone state (seen in diabetic nephropathy of chronic interstitial nephropathy) or obstructive nephropathy.
- Determine the presence of a renal origin for hyperkalemia using the urine potassium concentration.

This will determine the presence of a renal tubule dysfunction in a hyperkalemic patient. There are four types of urine chemistry analysis available to determine this: (1) Urine potassium (K) concentration, (2) the fractional excretion of potassium, (3) the urine potassium/creatinine ratio, and (4) the "transtubular potassium gradient" (TTKG). See Table 2 for the expected values of each in both renal and nonrenal causes of hyperkalemia.

LABORATORY TESTS

- Serum electrolytes, BUN, and creatinine
- Urinalysis and urine protein–creatinine ratio
- Serum and plasma potassium
- Plasma and urine osmolality
- Serum and urine creatinine
- Cortisol level
- Aldosterone level
- 18-hydroxycorticosterone

IMAGING STUDIES

- Ultrasound of the kidneys and bladder
- CT scan of the abdomen

Rx TREATMENT

- Supportive measurements such as fluids, pacing, and pressers do not work in the setting of hyperkalemia. In acute, severe, life-threatening hyperkalemia, the approach is divided into two components. First stabilize the myocardium to prevent a fatal arrhythmia. Giving IV calcium is cardioprotective in the setting of hyperkalemia, commonly reversing all hyperkalemic ECG changes within seconds of administration. However, it does not decrease the potassium levels; therefore, other therapies are needed to reduce the potassium level.
- Before giving calcium, make sure digoxin toxicity is not present, as calcium administration can be fatal in the face of digoxin-induced hyperkalemia.
- The aggressiveness of the treatment should be directly related to the rapidity with which the hyperkalemia developed, the absolute level of the potassium, and the evidence of toxicity by symptoms and/or examination and ECG changes. The more rapid the rise in potassium, the higher the level; and the more severe the cardiotoxicity depicted by the ECG changes, the more aggressive the therapy should be.

TABLE 2 Defining Renal Origin of Hyperkalemia

Application of TTKG, FE_K, and Urine K:Cr Ratio
Expected values for TTKG* or FE_K
Nonrenal forms of hyperkalemia
TTKG >5-7, FE_K >10%
Urine K:Cr ratio >30 mEq/L
Spot urine $[K^+]$ >25 mEq/L
Renal hyperkalemia
TTKG <5 or FE_K <10% (inappropriately low)
Urine K:Cr ratio <30 mEq/g Cr
Urine $[K^+]$ <25 mEq/24 h

*Prerequisites for use: UNa >25 mEq/L and urine not dilute.
Cr, Creatinine; *FE_K,* fractional excretion of K^+; *TTKG,* transtubular potassium gradient.
Formulae:
TTKG = (Urine K ÷ [Urine osmolality/Plasma osmolality]) ÷ Plasma K
FE_K = ([urine K^+]/[serum K^+])/(urine creatinine/serum creatinine)
Multiply by 100 for percentage

NONPHARMACOLOGIC THERAPY

- The mainstay of therapy should be educating the patient and the family regarding a low-potassium diet (<3 g/day), as well as providing a list of high-potassium foods to avoid.
- Maintaining adequate hydration and preventing volume depletion, which limits potassium excretion by the kidney.

ACUTE GENERAL Rx

In patients with severe hyperkalemia, treatment (Fig. 3) is as follows:

- IV calcium (Fig. 4) to ameliorate cardiac toxicity (if not digoxin toxic).
- Identify and remove sources of potassium intake.
- IV glucose and insulin infusion to enhance cellular uptake of potassium.
  1. Make sure to monitor closely for several hours for hypoglycemia, especially in advanced CKD patients.
- Correct severe acidosis with IV sodium bicarbonate.
- Consider beta-adrenergic agonist therapy (e.g., nebulized albuterol, 10 mg via venti mask), which is preferred over alkali therapy in patients with renal failure.
- Increase potassium excretion with administration of loop diuretic IV or cation-exchange medications mentioned previously.
  1. Medications that increase potassium excretion in addition to IV saline and loop diuretics include use of an aldosterone analogue (e.g., 9-alpha fludrocortisone acetate [Florinef]) in patients with hyporeninemia or hypoaldosteronism or patients with solid organ transplant on CNI and hyperkalemia.
- Emergency dialysis in potentially lethal hyperkalemia unresponsive to conservative measures or with acute kidney failure.
- Once the hyperkalemia has been corrected chronic management should be initiated to maintain a normal potassium with dietary restriction, adjusting/stopping medications associated with hyperkalemia, or use of the newer ion exchange resins sodium zirconium cyclosilicate and patiromer that are more palatable and better tolerated than sodium polystyrene sulfate.

CHRONIC Rx

In the presence of a moderate elevation of potassium and no ECG abnormalities:

- Correct the source of increase potassium (e.g., inhibited excretion or increased intake)
- Increase potassium excretion using cation exchange resin (Table 3) or diuretics:
  1. Historical therapy is sodium polystyrene sulfate with or without sorbitol. This may fall to the wayside in the face of the newer therapies with more consistent results and less potential toxicity (dose is 15 g to 30 g orally and may be repeated in 3 to 4 hours). *Caution:* Using large doses repeatedly may cause sodium overload and can potentially decompensate a patient with congestive heart failure. Do not give as an enema (especially with sorbitol). Rare cases of intestinal necrosis have been reported with use.
  2. Patiromer is a non-reabsorbed oral calcium-containing potassium-binding polymer suspension (dose 8.4 to 25.2 g daily).
     a. Shown to lower serum potassium in hyperkalemia associated with diabetic nephropathy and CHF on RAASi.
     b. Calcium is the ion exchanger (not sodium), and it can form calcium carbonate in the colon and affect absorption of some medications, especially ciprofloxin, levothyroxine, and metformin. Administer at least 3 hours before or after all oral medications.
     c. Can bind magnesium and be associated with hypomagnesemia; recommend monitoring magnesium levels intermittently in chronic use.
  3. Sodium zirconium cyclosilicate is a non-absorbed inorganic polymer selectively exchanging potassium for sodium and hydrogen ions (dose 10 g tid for up to 48

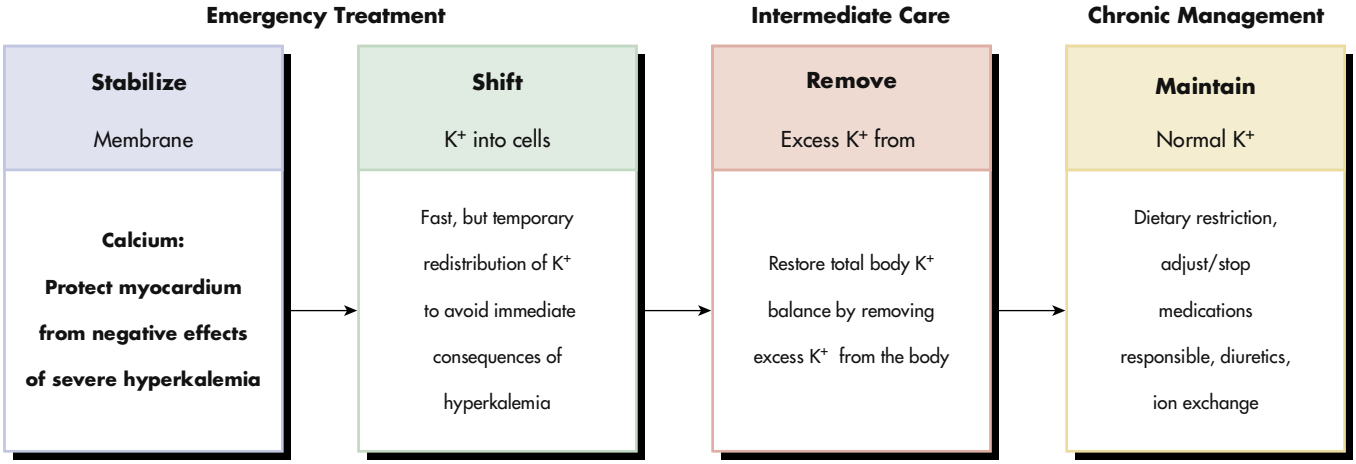

FIG. 3 Management of hyperkalemia.

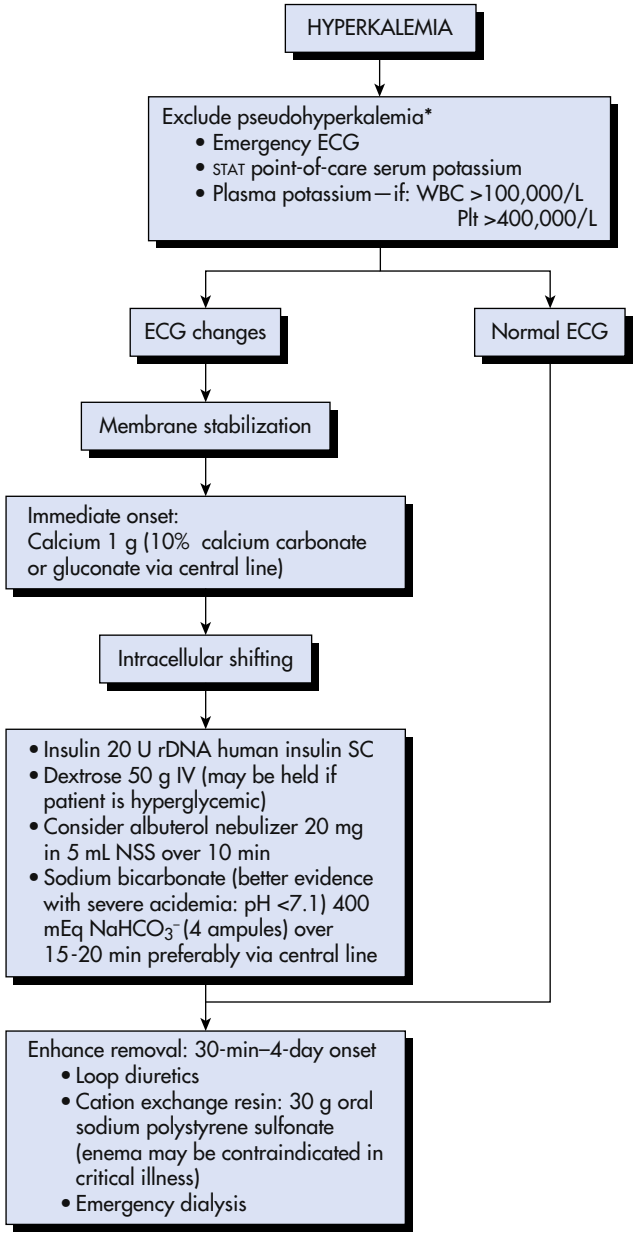

*May be unnecessary in appropriate clinical situation

FIG. 4 Algorithm for treatment of hyperkalemia. *ECG,* Electrocardiogram; *IV,* intravenously; *NSS,* normal saline solution; *Plt,* platelet count; *rDNA,* ribosomal deoxyribonucleic acid; *SC,* subcutaneously; *stat,* at once; *WBC,* white blood cell count. (From Ronco C et al: *Critical care nephrology,* ed 3, Philadelphia, 2019, Elsevier.)

TABLE 3 Available Potassium Ion Exchange Resins

	Sodium Polystyrene Sulfate	Patiromer	Sodium Zirconium Cyclosilicate
Dosage	15-30 g 1-4 times/day	8.4 g, 16.8 g, or 25.2 g Once daily	10 g, 3 times daily for up to 48 hr; then 5 g every other day to 15 g daily
Counterion	Sodium	Calcium	Sodium
Average daily sodium load	495-1980 mg	0 mg	400-2400 mg
Concomitant dose separation with other oral medications	3 hours separation (6 hours in patients with gastroparesis)	3 hours separation	2 hours separation

hours followed by 5 g every other day to 15 g daily for chronic use).
   a. Sodium is the ion exchanger and can be associated with sodium overload if large doses are used for prolonged time.
   b. Also must be administered at least 2 hours before or after all oral medications.

Management of nonurgent hyperkalemia:
- Discontinue or reduce medications that interfere with potassium excretion.
  1. Stop RAASi (special care if in combination)
  2. Stop spironolactone, eplerenone, amiloride, triamterene
  3. Stop all NSAIDs (including OTC) and COX-2 inhibitors
  4. Herbal medicine: stop Chan su and Noni juice
  5. If possible, address whether patient is on a calcineurin inhibitor (CNI)
- Prescribe a low-potassium diet (70 mEq/day).
- Give a loop diuretic (or thiazide of CNI-induced hyperkalemia).
- If bicarbonate <22, give $NaHCO_3$ tablets (650 mg tablet [7.6 mEq] or Shohl solution (sodium citrate) (3 to 60 ml tid).
- Patiromer or sodium zirconium cyclosilicate avoids use of SPS for chronic hyperkalemia.
  1. None of the ion exchange resins should be used for urgent hyperkalemia, some ongoing studies looking at sodium zirconium cyclosilicate
- May be able to continue RAASi with either patiromer or sodium zirconium cyclosilicate.

DISPOSITION
- Patients with acute symptomatic hyperkalemia with ECG changes should be admitted to a hospital in a monitored bed/intensive care unit.
- Asymptomatic patients with no ECG changes can be treated as outpatients and educated extensively regarding a low-potassium diet with close follow-up including a repeat potassium in 24 to 48 hr, depending on the severity, and a wk later.

REFERRAL
Patients with associated hypertension, proteinuria, CKD, or persistent hyperkalemia should be referred to a nephrologist for more intensive evaluation and to assess for a genetic etiology.

PEARLS & CONSIDERATIONS

COMMENTS
- Ensure that specimen is not hemolyzed.
- When in doubt, repeat the test.
- Rule out pseudohyperkalemia.
- Risk associated with comparable levels of hyperkalemia is higher in individuals with normal kidney function compared with those with increasingly severe CKD.
- Do not give IV calcium or insulin/dextrose if no ECG changes for hyperkalemia.
- Don't forget to educate and encourage dietary restriction of potassium. (Avoid salt substitutes.)
- Evaluate for urinary obstruction, especially in diabetics (neurogenic bladder) and in elderly males (prostatic hypertrophy).

PREVENTION
- Avoid dual therapy with ARB and ACEI or direct renin inhibitor.
- In patients with type 4 RTA, educate to reduce high-potassium food intake during their seasons (e.g., tomatoes, citrus fruits), avoid travel to areas where these foods are endemic and avoid volume depletion.
- In CKD patients or in patients with type 4 RTA, avoid using a salt substitute (which is potassium chloride).

PATIENT & FAMILY EDUCATION
Education regarding potassium content of foods is of high, practical importance. A renal nutritionist should review the patient's medical records for potential dietary interventions.

BASIC INFORMATION

DEFINITION

- Primary hyperlipoproteinemia is a group of genetic disorders of the lipid transport proteins in the blood that manifests as abnormally elevated levels of cholesterol, triglycerides, or both in the serum of affected patients.
- Usually defined as total cholesterol, LDL, triglycerides, or lipoprotein A levels above 90th percentile or HDL or apo A-1 levels below the 10th percentile for the general population. Fig. E1 illustrates the structure of lipoproteins. Plasma lipoprotein composition is described in Table E1.

SYNONYM

Hyperlipidemia

ICD-10CM CODES

E78.0	Pure hypercholesterolemia
E78.2	Mixed hyperlipidemia
E78.1	Pure hyperglyceridemia
E78.4	Other hyperlipidemia
E78.3	Hyperchylomicronemia

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The most common types are lipoprotein A excess, hypertriglyceridemia, and combined hyperlipidemia.

- Incidence of heterozygous familial hypercholesterolemia: 1:500
- Incidence of homozygous familial hypercholesterolemia: 1:1 million
- Familial hypercholesterolemia: Autosomal-dominant disorder
- Familial combined hyperlipidemia: Possibly an autosomal-dominant disorder
- Multifactorial predilection: Apparent in majority of affected individuals

GENETICS:

- Familial lipoprotein lipase deficiency: Autosomal recessive, resulting in an elevation in the plasma chylomicrons and triglycerides
- Familial apoprotein CII deficiency: Autosomal recessive, resulting in increased serum chylomicrons, very low-density lipoprotein (VLDL), and hypertriglyceridemia
- Familial type 3 hyperlipoproteinemia: Single-gene defect requiring contributory factors to manifest
- Familial hypercholesterolemia: Autosomal-dominant defect of the LDL receptor, resulting in an elevated serum cholesterol level and normal triglycerides
- Familial hypertriglyceridemia: Common, autosomal-dominant defect resulting in elevated VLDL and triglycerides
- Multiple lipoprotein–type hyperlipidemia: Autosomal dominant, manifesting as isolated hypercholesterolemia, isolated hypertriglyceridemia, or hyperlipidemia
- Polygenic hypercholesterolemia: Multifactorial
- Polygenic hyperalphalipoproteinemia: Autosomal dominant or polygenic, causing an elevated high-density lipoprotein
- A classification of lipoprotein disorders and their clinical findings and management are summarized in Table 2

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Familial lipoprotein lipase deficiency: Recurrent bouts of abdominal pain in infancy, eruptive xanthomas, hepatomegaly, splenomegaly, lipemia retinalis
- Familial apoprotein CII deficiency: Occasional eruptive xanthomas
- Familial type 3 hyperlipoproteinemia: Xanthoma striata palmaris or tuberoeruptive xanthomas, xanthelasmas, arterial bruits at a young age, gangrene of the lower extremities at a young age
- Familial hypercholesterolemia: Tendon xanthomas, arcus corneae, xanthelasma
- Familial hypertriglyceridemia: Associated obesity; eruptive xanthomas can develop with exacerbations

ETIOLOGY

- Genetic defects causing lipid abnormalities
- Environmental influences, including diet, drugs, and alcohol intake

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Secondary causes of hyperlipoproteinemias:

- Hypothyroidism
- Diabetes mellitus
- Pancreatitis
- Autoimmune hyperlipoproteinemia
- Nephrotic syndrome
- Biliary obstruction; Table E3 describes the differential diagnosis of hyperlipidemia and dyslipidemia

WORKUP

- Family history for premature cardiac disease
- Personal history of recurrent pancreatitis
- Detailed physical examination

LABORATORY TESTS

- Standard lipid profile; Table 4 summarizes laboratory findings in lipid disorders
- If normal, further testing with measurement of lipoprotein A, apo B, and apo A-1
- Lipoprotein electrophoresis and ultracentrifugation (for phenotypic classification)
- Workup for secondary causes: TSH, fasting glucose, liver function, renal function, urinary protein

TREATMENT

NONPHARMACOLOGIC THERAPY

- Cornerstone of treatment: Dietary therapy
  1. TLC diet (**t**herapeutic **l**ifestyle **c**hanges): See "Hypercholesterolemia" topic
- Risk factor reduction includes smoking cessation, treatment of hypertension, exercise
- Familial lipoprotein lipase deficiency and familial apoprotein CII deficiency: Fat-free diet
- Remainder of cases, except those with polygenic hyperalphalipoproteinemia: Fat- and cholesterol-restricted diets

ACUTE GENERAL Rx

No acute treatment is needed.

CHRONIC Rx

- Familial lipoprotein lipase deficiency, polygenic hyperalphalipoproteinemia, or familial apoprotein CII deficiency: No chronic drug therapy.
- Familial type 3 hyperlipoproteinemia: Usually responds well to secondary causes being treated and diet therapy; if not, fibric acids may be tried.
- Familial hypercholesterolemia: Statins, bile acid sequestrants, or niacin. Ezetimibe can be added to statins to achieve LDL goals. Alirocumab and evolocumab are subcutaneously injected PCSK9 (protein convertase subtilisin kexin type 9) inhibitors available as an adjunct diet and maximally tolerated statin therapy for adults with heterozygous familial hypercholesterolemia (HeFH). They can be added to statins and ezetimibe.
- Familial hypertriglyceridemia: Fibric acids (fenofibrate), niacin, omega-3 PUFA-containing fish oil capsules. Icosapent ethyl, a highly purified eicosapentaenoic acid ester, has been shown to lower triglyceride levels and cardiovascular risk in patients with hypertriglyceridemia.
- Multiple lipoprotein–type hyperlipidemia: Drug therapy aimed at the predominant lipid abnormality noted.
- Recent data suggest in patients with lipoprotein abnormalities that treatment goals should be based on non-HDL cholesterol rather than LDL cholesterol.
- The FDA has approved mipomersen and lomitapide in patients with homozygous familial hypercholesterolemia already taking maximum doses of other lipid-lowering drugs. Both medicines are hepatotoxic and very expensive.
- Recent trials with bempedoic acid, an inhibitor of ATP citrate lyase that lowers LDL cholesterol, have shown to significantly lower LDL when bempedoic acid was added to maximally tolerated statin therapy.

DISPOSITION

- Those with polygenic hyperalphalipoproteinemia: Excellent prognosis for longevity
- Those with familial hypercholesterolemia, familial type 3 hypercholesterolemia, or multiple lipoprotein–type hyperlipidemia: Even with aggressive treatment, at high risk for accelerated atherosclerosis and coronary artery disease

PEARLS & CONSIDERATIONS

COMMENTS

- Patient information is available through the American Heart Association.
- Lipid-lowering drug therapy is recommended for children ≥10 yr whose LDL-C levels remain extremely elevated after 6 mo to 1 yr of dietary modification. Drug therapy also can be considered for children with LDL-C levels of ≥190 mg/dl.

Hypernatremia

BASIC INFORMATION

DEFINITION

Hypernatremia is a clinical disorder that results from net water deficit (i.e., dehydration). It is identified when the serum sodium concentration (S_{Na}) exceeds the upper limit of normal (145 mEq/L). Hypernatremia does not reflect the net total body sodium content or extracellular fluid volume status. Consequently, patients may be hypovolemic, hypervolemic, or euvolemic when hypernatremic.

SYNONYMS

Hyperosmolality
Hypertonicity
High serum sodium concentration

ICD-10CM CODES

E87.0	Hyperosmolality and/or hypernatremia
E86.0	Dehydration

EPIDEMIOLOGY & DEMOGRAPHICS

The prevalence of hypernatremia varies based on the defined population and clinical setting. In the outpatient setting, it is reported at the extremes of age. Sixty percent of hypernatremia cases develop in hospitalized patients, and about 80% of these cases occur in intensive care units.

Among noncritical hospitalized patients, the prevalence rate of hypernatremia is 0.2% to 2.5%. The incidence is greater in critically ill and elderly patients, and the prevalence rate ranges from 10% to 26% in this population. Hypernatremia is independently associated with mortality.

RISK FACTORS:

- Age >60 yr
- Acute kidney injury on admission
- Altered mental status
- Mechanical ventilation
- Enteral tube feeding
- Negative fluid balance
- Hyperglycemia/uncontrolled diabetes mellitus
- Hypertonic bicarbonate or mannitol administration
- Hypokalemia
- Hypercalcemia
- Underlying polyuric disorders

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms generally correlate with the severity of hypernatremia, rapidity of development, and underlying cause. In the elderly, symptoms do not generally develop until the S_{Na} is >160 mEq/L.
- In mild hypernatremia, symptoms can include generalized muscle weakness, restlessness, anorexia, nausea, and vomiting.
- With severe hypernatremia, symptoms can begin with lethargy and irritability with progression to confusion, seizures, and, rarely, coma.
- In extreme scenarios, particularly in infants, hypernatremia-induced brain cell shrinkage can lead to intracranial bleeding from vascular stretching and consequent vessel rupture.
- Polydipsia and polyuria may be present in certain types of hypernatremia such as diabetes insipidus.
- Key elements of the history should focus on respective fluid and water intakes and losses, urine output, insensible losses, thirst response, and accessibility to water and fluids.
- Clinicians should evaluate the extracellular fluid volume status of patients. Classifying volume status will assist in determining the etiology and management of hypernatremia (Fig. 1).

ETIOLOGY

The etiology of hypernatremia is understood through the Edelman equation (refer to "Hyponatremia"). As a result, hypernatremia can be a clinical end-result of either net water deficit or excessive sodium intake. Renal water regulation and thirst stimuli are key physiologic components that prevent hypernatremia.

- To prevent hypernatremia, water is retained and urine concentrated by the kidneys under the influence of antidiuretic hormone or arginine vasopressin (AVP). Impairment of AVP secretion, reduction of the medullary concentration gradient, or an inability of AVP

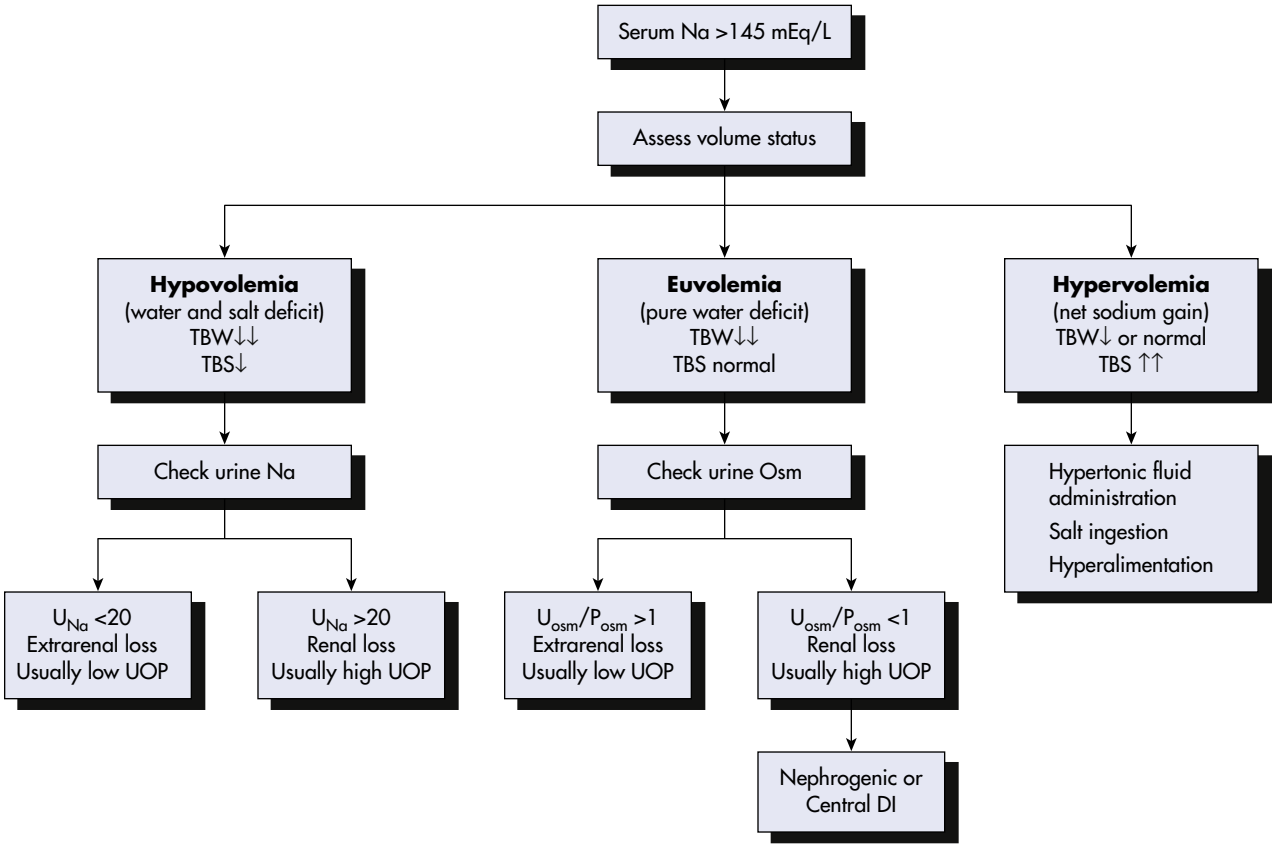

FIG. 1 Diagnostic approach to hypernatremia. *DI,* Diabetes insipidus; *Na,* sodium; *Osm,* osmolality; *TBS,* total body salt; *TBW,* total body water; *UOP,* urine output. (Adapted from Gilbert SJ, Weiner DE: *National Kidney Foundation primer on kidney disease,* ed 6, Philadelphia, 2017, WB Saunders.)

to stimulate insertion of aquaporin channels into the luminal membranes of collecting duct cells leads to excessive renal water losses and hypernatremia.

- Elevated plasma osmolality from hypernatremia triggers a thirst response by the hypothalamus. If water intake exceeds water loss or net solute gain, hypernatremia is avoided. Hypernatremia develops when the thirst response is impaired or when there is a lack of access to water, a common circumstance for mechanically ventilated patients and the elderly with cognitive impairments and physical limitations.

Hypernatremia can be classified in the following manner:

- Excessive water loss
  1. Gastrointestinal losses
     a. Vomiting or nasogastric losses
     b. Ileostomy
     c. Pancreaticobiliary fistula
     d. Diarrhea
     e. Laxatives
  2. Renal losses
     a. Osmotic diuresis
        (1) Osmotic diuretics (mannitol, sorbitol, glycine)
        (2) Glucosuria (hyperglycemia, SGLT2 inhibitor administration)
        (3) Urea diuresis (e.g., steroid use, high-protein diet, hypercatabolic state)
        (4) Postobstructive and post–acute tubular necrosis (post-ATN) diuresis
     b. Water diuresis
        (1) Central diabetes insipidus (CDI)
           (a) Genetic
              i. Autosomal dominant
              ii. Autosomal recessive
           (b) Acquired (e.g., post trauma, iatrogenic, craniopharyngioma, metastatic cancers, encephalitis)
           (c) Sarcoidosis
           (d) Multifocal Langerhans cell histiocytosis
           (e) Eosinophilic granulomatosis
        (2) Nephrogenic diabetes insipidus (NDI)
           (a) Genetic
              i. Arginine vasopressin receptor 2 (AVPR2) or aquaporin 2 (AQP2) gene mutations
              ii. Autosomal dominant polycystic kidney disease
              iii. Familial hypocalciuric hypercalcemia: Mutated calcium-sensing receptor
           (b) Acquired
              i. Chronic kidney disease
              ii. Post-ATN diuresis
              iii. Hypokalemia
              iv. Hypercalcemia (diverse causes)
              v. Drugs (e.g., lithium, amphotericin, ifosfamide, demeclocycline)
              vi. Gestation (increased placental vasopressinase)
- Impaired water intake
  1. Adipsia or hypodipsia
     a. Septooptic dysplasia
     b. Craniopharyngioma
  2. Impaired access to water
     a. Mechanical ventilation
     b. Dementia
     c. Cognitive impairment (e.g., dementia)
- Excessive sodium intake
  1. Hypertonic saline or sodium bicarbonate administration
  2. Salt tablet ingestion
  3. Salt-water drowning

An alternative classification based on the volume status of the patient is provided in Table 1.

TABLE 1 Causes of Hypernatremia

Hypovolemic Hypernatremia

Renal Loss
- Loop diuretics
- Post-AKI diuresis
- Postobstructive diuresis
- Osmotic diuresis (hyperglycemia, mannitol, urea)

Extrarenal Loss
- Gastrointestinal (diarrhea, nasogastric suctioning, vomiting)
- Skin (sweating, burns)

Euvolemic Hypernatremia

Renal Loss
- Diabetes insipidus (ADH-dependent mechanism)
  1. Central DI (complete or partial)
  2. Nephrogenic DI (X-linked recessive with defect in V2 receptor or aquaporin, unresponsive to ADH)
  3. Gestational DI
- Acquired Nephrogenic DI
  1. Electrolyte disturbances (hypercalcemia, hypokalemia)
  2. Drug-induced (amphotericin B, lithium, foscarnet)
  3. Chronic kidney disease (medullary cystic disease, sickle cell anemia, amyloidosis, Sjögren syndrome)
  4. Malnutrition

Extrarenal Loss
- Increased insensible loss (fevers, sweating, tachypnea)
- Decreased intake
  1. Primary hypodipsia
  2. Reset osmostat
  3. Decreased access to water (altered mental status, iatrogenic)
- Water loss into cells (seizures, exercise)

Hypervolemic Hypernatremia
- Excessive sodium administration (saline or bicarbonate)
- Hyperalimentation
- Salt ingestion
- Mineralocorticoid excess
- Hypertonic dialysis

ADH, Antidiuretic hormone; *AKI,* acute kidney injury; *DI,* diabetes insipidus.

Adapted from Gilbert SJ, Weiner DE: *National Kidney Foundation primer on kidney disease,* ed 6, Philadelphia, 2017, WB Saunders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Dehydration refers to net water deficits, and its clinical result is hypernatremia. Conversely, volume depletion occurs as a result of net loss of total body sodium and water, which results in decreased intravascular volume. Recognizing dehydration and volume depletion as distinct entities that may coexist has management implications. For example, euvolemic hypernatremia is due to pure water loss, and replacing water deficit is adequate therapy. This strategy is not appropriate in hypovolemic hypernatremia because volume (sodium and potassium) and water losses require replacement.

WORKUP

- Workup of hypernatremia begins with a detailed history and physical examination. Historical features that reveal volume depletion and/or dehydration are crucial and include a family history of diabetes insipidus and medication or drug use.
- In hospitalized patients, careful assessments of cumulative fluid intake and fluid losses must be made.
- In adults, hypernatremia usually develops from net water loss and inability to access water (e.g., altered mentation, mechanical ventilation). If access to water is not restricted, etiologies that impair thirst center function should be considered.
- In the presence of polyuria, the underlying etiology should be sought.

LABORATORY TESTS

- Serum chemistry: S_{Na} with serial repetition based on clinical scenario (e.g., 2 to 12 h). Frequent monitoring facilitates an appropriate correction rate of S_{Na} and evaluation of the response to therapy. Derangements of other electrolyte and renal parameters frequently accompany hypernatremia.
- Urine osmolality (U_{osm}): In the presence of a functioning hypothalamic-pituitary axis, a rise in plasma osmolality results in AVP-mediated urinary concentration (U_{osm} exceeds P_{osm}, typically >600 to 700 mOsm/kg). Thus, U_{osm} may signal the presence of DI.
  1. Low U_{osm} (<300 mOsm/kg) suggests hypernatremia from CDI or NDI. After an initial diagnostic workup is conducted, differentiation between CDI and NDI is required, as outlined in the "Diabetes Insipidus" section.
  2. High U_{osm} is usually from extrarenal water losses.
- Urine sodium (U_{Na}) and urine potassium (U_K): U_{NA} assists in the determination of intravascular volume (Fig. 1). Together, U_{NA} and U_K help to quantify urine electrolyte-free water clearance to guide therapy as explained later. Electrolyte-free water has no effective osmolality at equilibrium and is water comprised of no electrolytes with or without urea. Urinary parameters should be monitored every 12 to 24 h until S_{Na} is adequately corrected.

TREATMENT

- Treatment of hypernatremia requires the replacement of the existing water deficit and ongoing daily electrolyte-free water losses.
- Volume replacement may be required, and may take precedence when volume depletion is present.

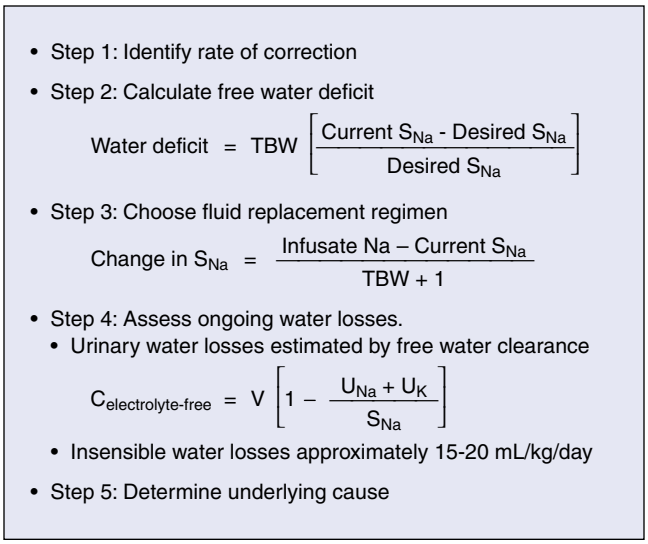

FIG. 2 Approach to treatment of hypernatremia. $C_{electrolyte\text{-}free}$, Electrolyte-free water clearance; *Na,* sodium; S_{Na}, serum sodium; *TBW,* total body water; U_K, urine potassium; U_{Na}, urine sodium; *V,* urine volume. (Adapted from Gilbert SJ, Weiner DE: *National Kidney Foundation primer on kidney disease,* ed 6, Philadelphia, 2017, WB Saunders.)

- A stepwise approach to the therapy of hypernatremia is depicted in Fig 2.
  1. Step 1: Identify the rate of correction, rate of rise of S_{Na}.
     a. Although the exact risk is unknown, too-rapid correction of chronic hyponatremia (>48 h) can have deleterious neurologic consequences, namely cerebral edema.
     b. Based on clinical data from infants and critically ill adults, chronic hypernatremia should not be corrected faster than 10 to 12 mEq/L per day or an average of 0.5 mEq/L per hour. This rate would apply to most nonhospitalized elderly patients, because hypernatremia develops over several days.
     c. In rare individuals with acute hypernatremia (e.g., intentional or accidental massive sodium ingestions), the S_{Na} may be rapidly corrected (within 24 h) to normal S_{Na} levels.
  2. Step 2: Calculate free water deficit.
     a. Free water deficit is the volume of free water required to correct the current S_{Na} to the target S_{Na}. This is estimated with the following formula:
        (1) Water deficit = TBW × [(current S_{Na}/target S_{Na}) – 1].
     b. In the preceding formula, TBW is the estimated total body water. Target S_{Na} is the S_{Na} that should be achieved in a 24-h period as determined in step 1.
     c. As a general estimate, TBW estimates are 50% to 60% of lean body weight in men and women.
  3. Step 3: Choose fluid replacement regimen.
     a. In patients with a pure water deficit, the calculated water deficit in step 2 should be replaced as either enteral water or intravenous D_5W. Do not infuse pure water by the intravenous route to prevent hemolysis.
     b. When possible, the enteral route should be used during hydration therapy to avoid overly rapid glucose infusions that may induce hyperglycemia, which promotes an osmotic diuresis. This pathophysiologic sequence may occur as D_5W infusion rates are increased to greater than 300 ml/h.
     c. The rate of replacement (ml/h) of the water deficit is obtained by dividing the calculated water deficit volume by 24 h. However, the ongoing rate of water losses must be addressed simultaneously.
     d. Because hypovolemia is present in more than 50% of cases of hypernatremia, concurrent volume replacement with isotonic fluid should be administered (0.9% sodium chloride [NaCl]) when appropriate. An alternative strategy is to use a single infusion of 0.45% saline solution that replaces salt and water. For example, 1 L of 0.45% NaCl adds 500 ml of water and 500 ml of 0.9% NaCl to the total body water.
     e. The change in S_{Na} with 1 L of a particular replacement fluid can be predicted by the following formula:
        (1) Change in S_{Na} = ($Na_{Infusate}$ – current S_{Na}) / (TBW + 1).
     f. This formula applies to the one-time administration of a 1-L infusate with a sodium concentration ($Na_{Infusate}$). $Na_{Infusate}$ concentrations for 0.45% saline, 0.9% saline, and 3% saline are, respectively, 77, 154, and 513 mEq/L.
  4. Step 4: Assess ongoing water losses.
     a. Ongoing daily water losses must be determined and added to the water deficit volume. Water losses occur from urinary water excretion and insensible losses from the skin, stool, and respiratory tract. Failure to account for these losses will result in undercorrection of hypernatremia.
     b. Urinary losses can be estimated by the electrolyte-free water clearance equation in Fig. 2.
     c. Insensible water losses can be estimated as 15 to 20 ml/kg/day.
- If hypernatremia is due to hypervolemia, consider the addition of loop diuretics to remove excess sodium.
- Evaluate for any underlying cause of hypernatremia and treat accordingly.
- Replace other electrolyte deficits such as potassium, and potassium deficits generally should be addressed before correction of hypernatremia.
- Repeat steps 1 through 4 until S_{Na} is reduced to approximately 140 to 145 mEq/L.
- The preceding formulas represent only guidance. Largely due to errors intrinsic to TBW estimation and fluid losses, underestimation or overestimation is common. Therefore, trend analysis of S_{Na} is critical. Serial measurements of S_{Na} must be evaluated with subsequent treatment based on results. Laboratory evaluations may be required at relatively brief intervals, that is, every 2 h during initial management.

DISPOSITION

Management of hypernatremia generally warrants inpatient admission because patients have underlying conditions that impair the thirst response.

REFERRAL

Nephrology consultation for management of hypernatremia and evaluation of underlying causes is appropriate. Endocrinology consultation may be warranted if diabetes insipidus is suspected.

PEARLS & CONSIDERATIONS

COMMENTS

- Hypernatremia is a problem of water deficit that is associated with an impaired thirst mechanism.
- Volume deficits may be present simultaneously.
- The rate of correction of S_{Na} includes determination of ongoing water losses and the water deficit.

BASIC INFORMATION

DEFINITION

Hyperparathyroidism is an endocrine disorder caused by excessive secretion of parathyroid hormone (PTH) from the parathyroid glands. Autonomous production of PTH resulting in hypercalcemia defines primary hyperparathyroidism. Secondary hyperparathyroidism occurs when the parathyroid glands appropriately increase PTH production in response to low calcium or vitamin D states. Primary hyperparathyroidism is the focus of this section.

ICD-10CM CODES

E21.0	Primary hyperparathyroidism
E21.1	Secondary hyperparathyroidism, not elsewhere classified
E21.2	Other hyperparathyroidism
E21.3	Hyperparathyroidism, unspecified
N25.81	Secondary hyperparathyroidism of renal origin

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Four cases per 100,000 persons per yr. Although malignancy is the most common cause of hypercalcemia in hospitalized patients, primary hyperparathyroidism is the most common cause of hypercalcemia in the outpatient setting.

PREVALENCE: Varies by country and race with approximately nine cases/1000 persons in the United States.

PREDOMINANT SEX AND AGE: Higher prevalence in women (female:male ratio 3 to 4:1) and older age (peaks in the seventh decade of life).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The majority of patients with primary hyperparathyroidism are asymptomatic. Diagnosis is usually considered in patients after an incidental discovery of elevated calcium or PTH levels on biochemical screening or during the evaluation for decreased bone mass. The development of symptoms varies with severity and rapidity of disease progression and reflects both the hypercalcemic and hyperparathyroid components of the disease process.

- Cardiovascular: Hypertension, shortened QT interval, bradycardia, arrhythmia, valvular calcification, left ventricular hypertrophy, increased mean carotid intima-media thickness
- GI: Anorexia, nausea, vomiting, constipation, abdominal pain, peptic ulcer disease, pancreatitis
- Genitourinary (GU): Nephrolithiasis, nephrocalcinosis, renal insufficiency, polydipsia, polyuria, nocturia, nephrogenic diabetes insipidus, renal tubular acidosis
- Musculoskeletal: Weakness, myopathy, bone pain, osteopenia, osteoporosis, gout, pseudogout, chondrocalcinosis, osteitis fibrosa cystica, subperiosteal bone resorption (Fig. E1)
- CNS: Confusion, anxiety, fatigue, lethargy, obtundation, depression, coma
- Other: Pruritus, metastatic calcifications, band keratopathy

ETIOLOGY

- Most cases of primary hyperparathyroidism are sporadic, but hyperparathyroidism can be associated with rare familial conditions such as multiple endocrine neoplasia (MEN-1 and MEN-2). Mutations in certain genes have been linked to tumor development in both sporadic and familial cases such as hyperparathyroidism-jaw tumor syndrome. Higher prevalence of hyperparathyroidism is noted with head and neck irradiation, chronic low calcium or vitamin D status, and lithium therapy.
- Pathologic characteristics include adenoma (80%), hyperplasia (15% to 20%), or carcinomas (<1%).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary hyperparathyroidism:
  1. Adenoma (80%)
  2. Hyperplasia (15% to 20%)
  3. Carcinomas (<1%)
- Secondary hyperparathyroidism precipitated by conditions that result in hypocalcemia:
  1. Renal calcium loss (i.e., medication: Loop diuretics and hypercalciuria)
  2. Calcium deficiency
  3. Vitamin D deficiency
  4. Malabsorption
  5. Chronic kidney disease (most common)
  6. Pseudohypoparathyroidism (PTH resistance)
  7. Inhibition of bone resorption (i.e., bisphosphonates and denosumab)
- Other causes of hypercalcemia include:
  1. Medications: Thiazide diuretics, lithium therapy
  2. Vitamin D intoxication, milk-alkali syndrome
  3. Familial hypocalciuric hypercalcemia (FHH)
  4. Renal failure (tertiary hyperparathyroidism)
  5. Thyrotoxicosis
  6. Granulomatous disorders (e.g., sarcoidosis)
  7. Malignancy (e.g., lung cancer, lymphoma, multiple myeloma, bone metastasis)
  8. Prolonged immobilization

WORKUP

- Typically, primary hyperparathyroidism is confirmed with an elevated serum calcium and PTH level.
  1. Two measurements of serum calcium are required for the confirmation of hypercalcemia. Total calcium should be corrected for low albumin utilizing the formula: Corrected Calcium = Serum Calcium + 0.8 × 4 − serum albumin. If a reliable laboratory is available, ionized calcium should be considered, especially in conditions associated with acid-base disturbances or low albumin states. Patients with primary hyperparathyroidism can also present with normal calcium levels (normocalcemic primary hyperparathyroidism).
  2. The serum intact PTH (iPTH) level is the single best test to evaluate the etiology of hypercalcemia. PTH is elevated or in the high normal range (i.e., inappropriately normal for an elevated calcium state) in primary hyperparathyroidism. PTH is decreased in most other conditions associated with elevated calcium.
- Other causes of hypercalcemia should be ruled out. These are typically associated with low PTH levels. Exceptions include lithium use and FHH.
  1. Review medication history to determine lithium, thiazide, vitamin D, or calcium intake.
  2. Check 24-hour urine calcium:creatinine to rule out FHH. Urine calcium is very low (<100 mg) and calcium clearance/creatinine clearance ratio is <0.01 in FHH. PTH can be normal or high in FHH.
  3. Consider PTH-related peptide (PTHrP) to evaluate hypercalcemia related to malignancies and vitamin D 1,25 to assess hypercalcemia secondary to granulomatous diseases or lymphomas.
  4. Multiple myeloma and bone metastasis can also result in a high calcium state and therefore must be appropriately evaluated.
- Rule out other causes of elevated PTH (i.e., secondary hyperparathyroidism). Serum calcium is typically low or low-normal in secondary hyperparathyroidism.
  1. Check calcium and 25 OH-vitamin D to rule out deficiency states.
  2. Check serum creatinine to assess renal function and 24-hour urine calcium and creatinine to evaluate renal loss.

LABORATORY TESTS

- Serum calcium (ionized or corrected calcium): Normal or elevated in primary hyperparathyroidism
- Serum phosphorus: Low or low-normal in primary hyperparathyroidism
- PTH: Elevated or high-normal in primary hyperparathyroidism
- Serum creatinine and estimated glomerular filtration rate (eGFR)
- 24-hour urine calcium and creatinine
- PTHrP and 1,25 OH-vitamin D levels 25 OH-vitamin D level
- ECG may reveal shortening of the QT interval secondary to severe hypercalcemia (>12 mg/dl)

IMAGING STUDIES

- Parathyroid localization with technetium-99m sestamibi (Figs. E2 and 3) can identify potential adenomas to help with surgical planning.
- Parathyroid ultrasound (Fig. 4) and computed tomography (CT) are also used to localize the parathyroid adenoma.

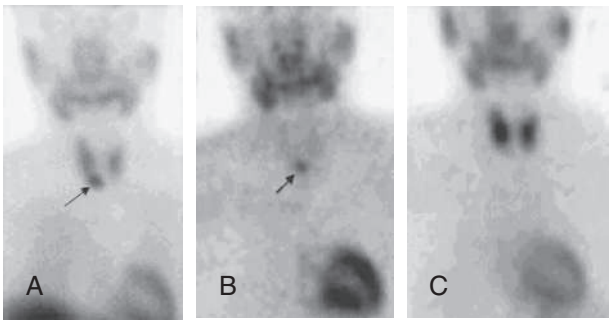

FIG. 3 Parathyroid adenoma. 99m Tc-MIBI images at 10 min **(A)** and 3 h **(B)** showing a persistent focus of activity inferior to the right lobe of the thyroid; 99m TcO 4 image **(C)** shows normal thyroid uptake but the adenoma is not visualized. (From Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

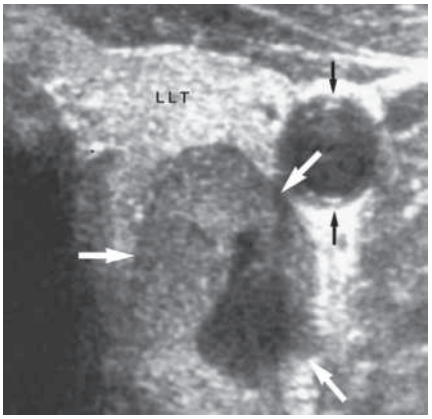

FIG. 4 High-resolution US of the left lobe of the thyroid (LLT) anterior to a parathyroid adenoma *(white arrows).* There is a small area of cystic degeneration within the posterior aspect of the adenoma. Carotid artery *(black arrows).* (From Adam A et al: *Grainger & Allison's diagnostic radiology,* ed 5, 2007, Churchill Livingstone; in Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

FIG. 6 Secondary hyperparathyroidism. Lateral radiograph of the thoracic spine demonstrating increased sclerosis along the end-plates and increased lucency of the central part, giving a "rugger jersey" spine appearance. Also note deformity of the vertebral bodies, with loss of height and increased diameter, in addition to wedge-shaped deformities at the upper thoracic spine related to decreased stability and weakness of the abnormal bone. (From Adam A et al: *Grainger and Allison's diagnostic radiology,* ed 6, 2015, Elsevier; in Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

- Bone mineral density (BMD) imaging of the spine, hip, and forearm (distal third of radius) is recommended for all patients with hyperparathyroidism in order to assess the risk for osteoporosis and fragility fractures. Plain radiographic abnormalities are illustrated in Figs. E5 and 6. Cortical bone loss (i.e. forearm) is greater than trabecular bone loss (i.e. hip and spine) in hyperparathyroidism.
- Renal ultrasound can be considered to assess asymptomatic renal stones.

Rx TREATMENT

Modality of treatment depends on disease progression and which patients are more likely to suffer end-organ effects of hyperparathyroidism or benefit the most from surgery. Fig. 7 illustrates an algorithm for managing persistent or recurrent hyperparathyroidism.

- Surgery is the only definitive treatment for symptomatic primary hyperparathyroidism. Surgery can normalize calcium levels, decrease the risk for kidney stones, improve bone mineral density and fracture risk, and enhance quality of life measures.
  1. Indications for parathyroidectomy (Box 1):
     a. All patients younger than 50 yr
     b. Hypercalcemia (Ca >1 mg/dl above upper limit normal)
     c. Creatinine clearance <60 ml/min
     d. 24-h urine for calcium >400 mg/dl (>10 mmol/dl)
     e. Presence of nephrolithiasis or nephrocalcinosis by x-ray, ultrasound, or CT
     f. Osteoporosis
        (1) Bone mineral density (BMD) by dual-energy x-ray absorptiometry (DXA): T-score ≤2.5 at lumbar spine, total hip, femoral neck, or distal third of radius
        (2) Vertebral fracture by x-ray, CT, MRI, vertebral fracture assessment (VFA) by DXA
  2. Surgical approaches include:
     a. Minimally invasive parathyroidectomy has increased in popularity. The surgeon will identify and remove the abnormal gland that was identified on preoperative imaging. This technique has limited dissection and has improved recovery time. Intraoperative monitoring of PTH level is done to ensure the removal of the abnormal gland. Fall of PTH level by 50%, into the normal range, is expected within 10 to 15 min after removal of the abnormal gland.
     b. Bilateral neck exploration under general anesthesia is the traditional surgical approach. All parathyroid glands are identified and compared. An experienced endocrine surgeon cures >95% of patients undergoing bilateral neck exploration. Potential complications include transient and permanent hypocalcemia secondary to hypoparathyroidism and recurrent laryngeal nerve injury.
- Ablation therapy (e.g., ethanol, angiographic, radiofrequency) can be considered in patients who are not surgical candidates. Limited data are available on efficacy and side effects. Repeat ablations may be required if hypercalcemia persists.
- Medical management:
  1. Avoid medications that precipitate hypercalcemia (e.g., thiazide or lithium)
  2. Because inadequate calcium and vitamin D status stimulates PTH, it is not necessary to significantly restrict calcium and vitamin D intake. Vitamin D replacement safely improves vitamin D level and decreases PTH level without significantly increasing serum calcium level and urinary calcium excretion. Repletion of vitamin D is recommended in patients whose levels are <30 mg/dl (75 mmol/L). Dietary calcium intake should be approximately 1000 mg/day.
  3. Encourage physical activity since immobilization increases bone resorption.
  4. Recommend adequate hydration (at least 2 L) to minimize the risk of nephrolithiasis.
     a. For patients who are not surgical candidates or who refuse surgery, pharmacologic options are available. The choice of pharmacologic agents is dependent on the desired goal. Cinacalcet (Sensipar) is an oral calcimimetic agent that activates the calcium sensing receptor in the para-

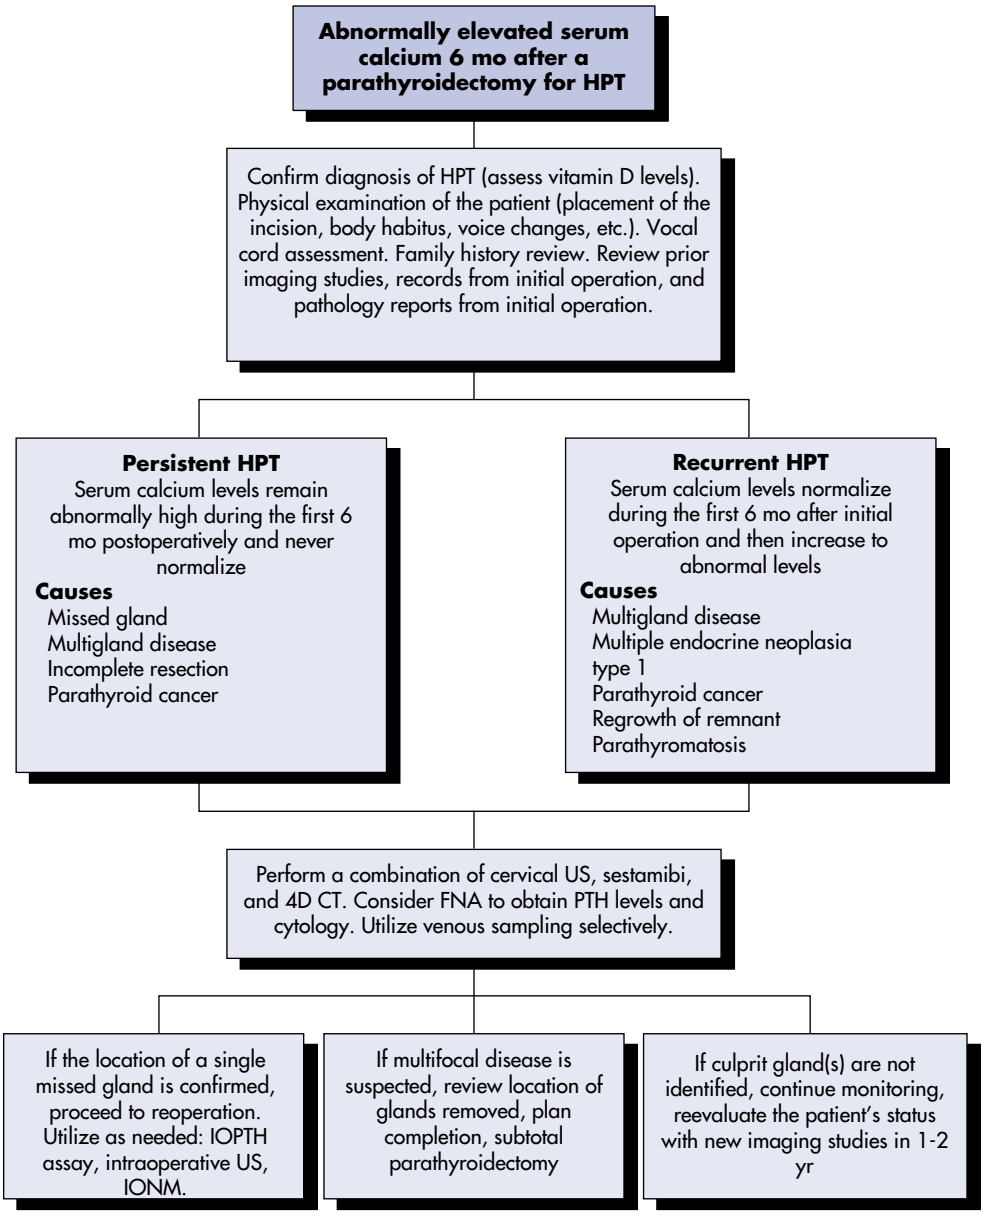

FIG. 7 Algorithm for managing persistent or recurrent hyperparathyroidism (HPT). *4D CT*, Four-dimensional computed tomography; *FNA*, fine-needle aspiration; *IONM*, intraoperative neurophysiologic monitoring; *IOPTH*, intraoperative parathyroid hormone; *PTH*, parathyroid hormone; *sestamibi*, technetium (^{99m}Tc) sestamibi imaging; *US*, ultrasonography. BOX 1 Indications for Parathyroidectomy in Patients With Secondary and Tertiary Hyperparathyroidism

Indications for Parathyroidectomy in Patients with Secondary Hyperparathyroidism (SHPT)

SHPT refractory to medical therapy:
- Parathyroid hormone >1000 pg/ml
- Calcium × Phosphorus product >55

Renal osteodystrophy
Calciphylaxis
Other retractable symptoms, including uremic pruritus, persistent anemia, bone pain, muscle pain, abdominal pain, fatigue, and weakness

Indications for Parathyroidectomy in Patients With Tertiary Hyperparathyroidism

Severe hypercalcemia (calcium >12.5 mg/dl)
Persistent hypercalcemia ≥2 yr after renal transplantation, associated with:
- Decline in renal function, without graft rejection
- Nephrolithiasis
- Progressive bone disease
- Pancreatitis

From Cameron JL, Cameron AM: *Current surgical therapy*, ed 12, Philadelphia, 2017, Elsevier.

thyroid gland. It decreases PTH production and subsequently normalizes or decreases serum calcium levels, without significant BMD changes. It is indicated for the treatment of severe hypercalcemia in patients with primary hyperparathyroidism who are unable to undergo surgery. It is also indicated for the treatment of secondary hyperparathyroidism associated with chronic kidney disease and for hypercalcemia associated with parathyroid carcinoma.

b. Agents such as bisphosphonates (e.g., alendronate, zoledronate) that inhibit bone resorption and increase BMD should be considered when improvement in BMD is the primary goal in patients with hyperparathyroidism.

- Medical monitoring is recommended for asymptomatic primary hyperparathyroidism. The majority of patients do not manifest disease progression during observation. However, approximately 25% of asymptomatic patients require surgery over a 10-yr follow-up period.
  1. Indications for medical monitoring:
     a. Clinically asymptomatic and >50 yr old
     b. Serum calcium level only mildly elevated (<1 mg/dl above upper limit normal)
     c. GFR >60 ml/min and no nephrolithiasis or nephrocalcinosis
     d. No evidence of osteoporosis
     e. Medically unfit for surgery or refusing surgery
- Symptoms should be assessed regularly. Serum calcium, PTH, creatinine, and eGFR should be checked semiannually. DXA performed at three sites every 1 to 2 yr or vertebral fracture assessment of the spine is clinically indicated (e.g., height loss, back pain).

ACUTE GENERAL Rx

Severe and/or symptomatic hypercalcemia may require hospitalization, especially if serum calcium >12 mg/dl. Acute management of hypercalcemia includes:

- Vigorous hydration with IV normal saline (2 to 4 L/day). Fluid status must be monitored in patients with cardiac dysfunction or renal insufficiency in order to avoid fluid overload.
- Bisphosphonates can effectively decrease calcium levels. Zoledronate (4 mg IV over 15 min) or pamidronate (60 to 90 mg IV over 4 hours) are both effective. Onset of action is 24 to 48 hours.
- Calcitonin (4 units/kg IM/SC every 12 hours) may be used with bisphosphonates to achieve a more rapid reduction of calcium levels. Onset of action is within hours.

PEARLS & CONSIDERATIONS

COMMENTS

- Parathyroidectomy should be considered for all patients with symptomatic hyperparathyroidism. If surgery is contraindicated or not desired, cinacalcet and bisphosphonates can be used.
- Asymptomatic patients can be monitored with serial calcium, creatinine, eGFR, and bone mineral density measurements. Disease progression may result in surgery.
- Most patients can be managed medically by limiting factors that result in hypercalcemia (e.g., dehydration, immobilization, thiazide diuretics) and maintaining normal calcium and vitamin D intake.
- Patients with osteopenia and high fracture risk may require antiresorptive therapy such as bisphosphonates.

BASIC INFORMATION

DEFINITION

Hypersensitivity pneumonitis (HP) is a group of immunologically mediated pulmonary diseases, with or without systemic manifestations (e.g., fever, weight loss), caused by the inhalation of an antigen to which the patient is sensitized and hyperresponsive. Sensitization and exposure alone in the absence of symptoms do not define the disease.

SYNONYMS

HP - Extrinsic allergic alveolitis (EAA)
Bird fancier's lung
Farmer's lung
Malt worker's lung
"Ventilation" pneumonitis
Maple bark-stripper's lung
Sauna taker's lung
Hot tub lung

ICD-10CM CODES

J67.x Hypersensitivity pneumonitis due to specific organic dusts
J67.9 Hypersensitivity pneumonitis due to unspecified organic dust

EPIDEMIOLOGY & DEMOGRAPHICS

- Estimates of the prevalence and incidence of HP vary considerably and depend on the definition and methods used to establish the diagnosis.
- Clinical presentation depends on the intensity of exposure, environmental conditions, and genetic risk factors that remain poorly understood.
- More than 300 causative agents have been identified, and the number continues to grow.
- Causative agents in residential and occupational exposures include birds, mold, humidifiers, fountains, steam irons, dry sausage molds, moldy cheese, contaminated wood, biofilm contained within wind instruments (e.g., trombone, saxophone), and organic and inorganic chemicals, including metalworking fluids.
- It is likely that genetic factors are also involved that result in an exaggerated lung response to an offending agent. The major histocompatibility complex is the most studied thus far.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Vary depending on frequency and intensity of antigen exposure.

- Acute: Fever, cough, malaise, and dyspnea 4 to 6 hours after an intense exposure. Symptoms resolve with removal of the inciting agent, typically within 12 to 24 hours
- Often misdiagnosed initially as a viral illness or asthma
- Subacute: Insidious onset of productive cough, dyspnea on exertion, anorexia, and weight loss, usually from a heavy, sustained exposure
- Chronic: Gradually progressive cough, dyspnea, malaise, and weight loss, usually from low-grade or recurrent exposure
- Physical examination: Hypoxemia, cyanosis, rales, possible fever

ETIOLOGY

- Numerous environmental agents, often encountered in occupational settings.
- Common sources of antigens: "Moldy" hay, silage, grain, or vegetables; bird droppings or feathers (including those found commonly in down pillows, blankets, and upholstered furniture); low-molecular-weight chemicals (e.g., isocyanates); pharmaceutical products.
- Fig. E1 illustrates the pathogenesis of hypersensitivity pneumonitis.

DIAGNOSIS

- Accurate diagnosis is important for differentiating HP from other interstitial lung diseases because the prognosis and treatment may differ.
- The clinical syndrome of acute HP is indistinguishable from an acute respiratory infection with a history of illness occurring within hours of exposure to an antigen.
- Need high index of suspicion.
- Detailed occupational and home exposure history is required.
- Lung biopsy is often necessary for diagnosis.

DIFFERENTIAL DIAGNOSIS

Acute Stages	Chronic Stages
Allergic bronchopulmonary aspergillosis	Idiopathic pulmonary fibrosis (IPF)
Pulmonary embolism	Bronchiectasis
Asthma	Chronic bronchitis
Aspiration pneumonia	Nonspecific interstitial pneumonia (NSIP)
Bacterial pneumonia	Connective tissue–related lung disease
Fungal or mycobacterial pneumonia	Sarcoidosis
Bronchiolitis obliterans–organizing pneumonia	
Eosinophilic pneumonia	
Churg-Strauss syndrome	
Wegener granulomatosis	

WORKUP

No single radiologic, physiologic, or immunologic test is specific for the diagnosis of HP. HP must be suspected in any patient presenting with cough, dyspnea, fever, and malaise. A thorough history focusing on potential exposures is essential. Table 1 describes examples of occupational causes of HP.

Environmental and occupational history questions should ask about grain dusts, animal handling, food processing, cooling towers, fountains, metal-working fluids, symptom improvement away from exposure, pets (particularly

TABLE 1 Examples of Occupational Causes of Hypersensitivity Pneumonitis

Occupation	Cause
Farmer	Thermophilic actinomycetes in moldy hay
Metal worker	Contamination of metal-working fluids with microorganisms such as *Mycobacteria immunogens* or fungi
Worker exposed to humidifiers	Contamination with microorganisms such as protozoa or fungi
Sugarcane worker	Moldy sugarcane (bagassosis)
Maple bark stripper	Fungi
Chicken or turkey worker	Avian proteins
Pharmaceutical worker	Penicillin
Food handler	Soybeans
Office worker	Microorganisms contaminating air conditioners or humidifiers
Swimming pool attendant	Fungal contamination in sprays around pool area
Animal worker	Rat proteins
Mushroom worker	Fungi
Wheat farmer or handler	Weevil-infested flour
Greenhouse worker	Fungi
Workers spraying urethane paint or adhesives/sealants (or less often, other workers using diisocyanate)	Methylene diphenyl diisocyanate, hexamethylene diisocyanate, toluene diisocyanates
Chemical worker using plastics, resins, paints	Trimellitic anhydride

From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.

birds), hobbies involving chemicals, feathers, or fur, organic dusts, presence of humidifiers, dehumidifiers, or hot tubs/saunas, leaking or flooding indoors, visible fungal growth in living or working environment, feather pillows, bedding, or upholstered furniture.

Major diagnostic criteria:

- History of compatible clinical symptoms, physical exam, changes on chest radiograph or high-resolution CT (HRCT) of the chest, and pulmonary function tests. Particularly suspicious if symptoms appear to worsen within hours after antigen exposure
- Confirmation of exposure to the offending agent by history, investigation of the environment, serum precipitin tests to potential agents (often referred to as a "hypersensitivity panel" by many labs)
- BAL fluid lymphocytosis (if performed)
- Compatible histologic changes by lung biopsy (if performed): Poorly formed granulomas or mononuclear cell infiltrate
- Positive natural challenge (reproduction of symptoms and laboratory abnormalities after exposure to the suspected environment) or controlled inhalation challenge

LABORATORY TESTS

- Routine laboratory tests do not make the diagnosis, but typically the erythrocyte sedimentation rate, C-reactive protein, lactate dehydrogenase, and leukocyte count are increased; elevated immunoglobulins IgG and IgM are nonspecific; rheumatoid factor (RF) and immune complexes are often positive; peripheral eosinophil count and serum IgE are generally normal.
- Lactate dehydrogenase (LDH) is increased and tends to decrease with improvement.
- Pulmonary function tests: Restrictive ventilatory pattern is typically seen. Decreased FEV_1, decreased forced vital capacity, decreased total lung capacity, decreased diffusion capacity, and decreased static compliance.
- Arterial blood gases show mild hypoxemia (worsens with exercise).
- A-a gradient shows slight increase.
- Serum precipitin test for IgG antibodies against offending antigen may be positive in serum. Precipitins are sensitive but not specific for HP (asymptomatic patients may have IgG antibodies in serum). HP may also be present without a positive precipitin test.
- Skin testing is generally not helpful in establishing a diagnosis.

IMAGING STUDIES

Chest x-ray: Nonspecific; may be normal in early stage.

- Acute/subacute: Bilateral interstitial and alveolar nodular infiltrates in a patchy or homogeneous distribution.
- Chronic: Diffuse reticulonodular infiltrates and fibrosis.

High-resolution chest CT scan (Fig. 2): No pathognomonic features but demonstrates airspace and interstitial patterns in the acute and subacute stage. The chronic stage reveals honeycombing, air trapping, and bronchiectasis.

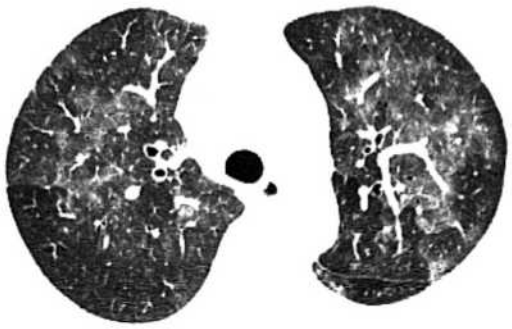

FIG. 2 In this patient with hypersensitivity pneumonitis, patchy ground-glass opacity is visible bilaterally. (From Mason RJ: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, WB Saunders.)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Early recognition and avoidance of the causative antigen

ACUTE GENERAL Rx

- Glucocorticoids accelerate initial lung recovery but may have no effect long term (from a controlled study in farmer's lung). No prospective, randomized, placebo-controlled trials for other types of HP or subacute and chronic stages.
- Prednisone 0.5 to 1 mg/kg usually over 1 to 2 wk then tapered over 4 wk. Some patients, particularly those with subacute or chronic presentation, may require a longer course of therapy.

DISPOSITION/PROGNOSIS

Prognosis is generally better in patients with acute or subacute HP. Prognosis is worse in those with older age, desaturation during exercise, and findings of severe fibrosis by lung biopsy.

Acute: 4 to 48 hours

- Clinical: Fever, chills, cough, hypoxia, malaise
- HRCT: Ground-glass infiltrates
- Immunopathology: Poorly formed, noncaseating granulomas or mononuclear cell infiltration in a peribronchial distribution, frequently with giant cells
- Prognosis: Good

Subacute: Wks to 4 mo

- Clinical: Dyspnea, cough, episodic flares
- HRCT: Micronodules, air trapping
- Immunopathology: More well-formed, noncaseating granulomas, bronchiolitis, organizing pneumonia, and interstitial fibrosis
- Prognosis: Good

Chronic: 4 mo to yr

- Clinical: Dyspnea, cough, fatigue, weight loss
- HRCT: Fibrosis (possible), honeycombing, emphysema
- Immunopathology: Granulomatous inflammation may be seen in addition to bronchiolitis obliterans (with or without organizing pneumonia) and honeycombing and fibrosis, lymphocytic infiltration, centrilobular and bridging fibrosis, neutrophil-mediated air space destruction, giant cells
- Prognosis: Generally poor

REFERRAL

- Bronchoscopy: BAL provides useful supportive data in the diagnosis of HP. Usually reveals intense lymphocytosis (typically T cells >50%) of predominantly CD8+ suppressor cells. In the acute stage, neutrophils predominate, but as the disease progresses to chronic form, the ratio of CD4+ to CD8+ cells increases. When fibrosis is present the number of neutrophils increases.
- Lung biopsy: The histopathologic features of HP are distinctive but not pathognomonic. Bronchiolitis and interstitial pneumonitis with granuloma formation typically is seen. Variable degrees of interstitial fibrosis are seen in the chronic form. Chronic HP may be difficult to distinguish from IPF or NSIP pathologically.
- Laboratory inhalation challenge: Testing to prove a direct relation between a suspected antigen and disease; extract of antigen is inhaled by nebulizer.

PEARLS & CONSIDERATIONS

A clinical prediction rule using six features has high specificity and sensitivity for the diagnosis of acute and subacute HP:

- Exposure to a known offending agent
- Positive specific precipitating antibody
- Recurrent episodes of symptoms
- Inspiratory crackles
- Symptoms occurring 4 to 8 hr after exposure
- Weight loss

HP occurs more frequently in smokers than nonsmokers (likely from an immunosuppressive effect).

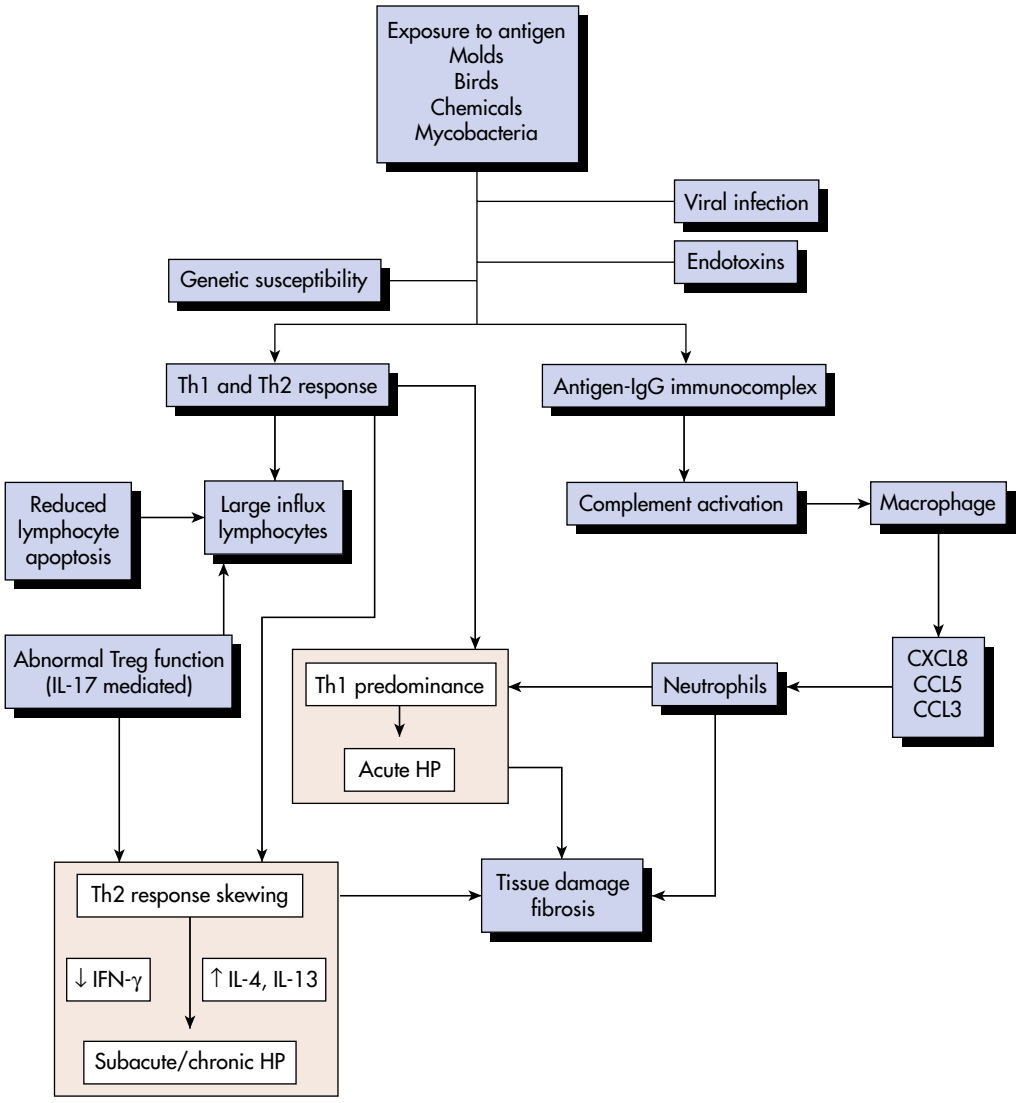

FIG. E1 Pathogenesis of hypersensitivity pneumonitis (HP). Chronic and repeated exposure to antigens in genetically susceptible individuals triggers an inflammatory process. A T-helper (Th) 1 response predominates in the early stages, whereas Th2 skewing occurs in later stages, both leading to tissue damage from inflammatory propagation and cytokine release. Lung tissue lymphocytes are increased because of decreased lymphocyte apoptosis and impaired regulatory T cell (Treg) function (mediated by interleukin [IL]-17). Early inflammatory changes include IgG binding to antigen and complement pathways with macrophage activation and secretion of chemoattractants (CXCL8, CCL5, CCL3) that induce neutrophilic airway infiltration and tissue destruction. *IFN,* Interferon; *Ig,* immunoglobulin. (From Adkinson NF et al: *Middleton's allergy principles and practice,* ed 8, Philadelphia, 2014, WB Saunders.)

BASIC INFORMATION

DEFINITION

Hypersplenism is a syndrome characterized by splenomegaly, cytopenias (one or more of the following: Anemia, thrombocytopenia, or leukopenia), and compensatory hyperplastic bone marrow. These cytopenias are correctable with splenectomy.

ICD-10CM CODE
D73.1 Hypersplenism

EPIDEMIOLOGY & DEMOGRAPHICS

Most often seen in patients with liver disease, hematologic malignancy, and infection.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms depend on the size of the spleen, rate of growth, and underlying disease
- History: Early satiety, abdominal discomfort or fullness, acute left upper quadrant (LUQ) pain (infarction, sequestration crisis), referred pain to left shoulder
- Physical examination: Splenomegaly (normal spleen usually not palpable), LUQ tenderness, presence of a rub in LUQ (suggestive of splenic infarct), stigmata of cytopenias

ETIOLOGY

- The spleen is an important component of the hematologic and immune systems (antigen processing and antibody synthesis). The spleen is responsible for the modification (removal of particles and parasites) and clearance of senescent or poorly deformable red blood cells (RBCs). It also filters blood, removing foreign particles (microorganisms) and other particulates (e.g., complement- or antibody-coated cells) from the circulation. The spleen is a platelet reservoir, storing 30% of platelet mass. It can become the site of hematopoiesis in certain disease states. The spleen's normal activities are augmented when enlarged.
- Splenomegaly increases the proportion of blood channeled through the red pulp, causing inappropriate splenic pooling of both normal and abnormal blood cells. The size of the spleen determines the amount of cell sequestration. Up to 90% of platelets may be pooled in an enlarged spleen. Prolonged sequestration leads to increased destruction of RBCs. Platelets and white blood cells (WBCs) have about normal survival time even when sequestered and may be available if needed.
- Splenomegaly exacerbates cytopenias by dilution, possibly due to plasma volume expansion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Hypersplenism can be caused by splenomegaly of almost any cause.

- Splenic congestion: Cirrhosis (portal hypertension); congestive heart failure; portal, splenic, or hepatic vein thrombosis
- Hematologic causes: Hemolytic anemia, spherocytosis, elliptocytosis, sickle cell anemia, thalassemia, extramedullary hematopoiesis, chronic transfusions, following use of granulocyte colony-stimulating factor
- Infections: Viral (hepatitis, infectious mononucleosis, cytomegalovirus, HIV/AIDS), bacterial (endocarditis, sepsis, tuberculosis, salmonella, brucella), parasitic (babesiosis, malaria, leishmaniasis, schistosomiasis, toxoplasmosis), fungal
- Malignancy: Acute or chronic leukemia, lymphoma, myeloproliferative diseases (polycythemia vera, essential thrombocythemia, myelofibrosis), splenic or metastatic tumors
- Inflammatory diseases: Rheumatic fever, rheumatoid arthritis (Felty syndrome), systemic lupus erythematosus, sarcoid, serum sickness
- Infiltrative diseases: Amyloidosis, Gaucher disease, Niemann-Pick disease, glycogen storage disease

WORKUP

History (including travel), physical examination, laboratory tests, imaging studies

LABORATORY TESTS

- CBC with differential: Cytopenias, neutrophilia (infection)
- Peripheral smear: RBC and WBC morphology (abnormal cells may suggest infection, malignancy, bone marrow disease, rheumatologic disease), organisms (bacteria, malaria, babesiosis)
- Bone marrow aspiration/biopsy: Hyperplasia of cytopenic cell lines; hematologic, infiltrative, or infectious disorders
- Tests to diagnose suspected cause of splenomegaly: Liver function, hepatitis serology, HIV, rheumatoid factor, antinuclear antibody, tissue biopsy
- NOTE: Red cell mass (^{51}Cr assay) may be used to assess severity of anemia. RBC mass measurement will differentiate true anemia (decrease in RBCs) from dilutional anemia (plasma volume expansion)

IMAGING STUDIES

Choice of imaging study depends on suspected underlying pathology.

- Ultrasound: Splenic size, presence of cyst or abscess
- CT with contrast: Estimate volume, obtain structural information: Cyst, abscess, malignancy
- MRI: Most useful for assessing vascular lesions and infections
- Nuclear medicine: Liver-spleen scan: Assess anatomy and function; may suggest presence of portal hypertension
- Consider additional tests as suggested by history and exam: Chest radiograph, echocardiogram, PET scan

TREATMENT

ACUTE GENERAL Rx

- Treat underlying disease
- Splenectomy is considered if:
  1. Indicated for the management of the underlying cause
  2. Persistent symptomatic disease (severe cytopenia) not responding to therapy
  3. Necessary for diagnosis

RISKS:

- Infections (especially encapsulated organisms): Risk greatest in the first 2 yr after splenectomy. Asplenic patients have a twofold to threefold increase of sepsis and infection-related mortality. Attempts to decrease risk include:
  1. Immunization with pneumococcal (PCV13 and PPSV23), meningococcal (MenACWY and MenB), and *Haemophilus influenza* type b (Hib) vaccines (if not previously vaccinated) at least 2 wk before splenectomy. Preferred: PCV13 vaccination followed by PPSV23 vaccination at least 8 wk later. If already immunized with PPSV23, PCV13 vaccine should be given at least 1 yr later. Revaccination with PPSV23 in 5 yr and again after age 65 yr (and 5 yr after most recent dose). Revaccination for meningococcal (MenACWY) every 5 yr. Annual inactivated or recombinant influenza vaccination. NOTE: If unable to vaccinate 2 wk before splenectomy, vaccinate 2 wk after surgery. Ensure all age-appropriate vaccinations are up to date.
  2. Prophylactic antibiotics after splenectomy in highest-risk patients.
  3. Patient education regarding the importance of rapid initiation of antibiotics and seeking emergent care at the first sign of infection.
- Thromboembolic complications, especially high risk of portal vein thrombosis.
- Possible increased risk of atherosclerotic heart disease and cancer.
- Splenectomy should not be performed if the spleen is the main site of hematopoiesis as a result of bone marrow failure (e.g., myelofibrosis).
- Other options include partial splenectomy, partial splenic artery embolization, radiofrequency ablation, portosystemic shunting (for congestive splenomegaly).

DISPOSITION

- Cytopenias are usually correctable with splenectomy; normal cell counts return within a few weeks.
- Splenectomy may alleviate portal hypertension.
- Prognosis depends on the underlying disease.

REFERRAL

Hematology

PEARLS & CONSIDERATIONS

Thrombocytopenia in hypersplenism is usually moderately severe (>50 × 10^9/L) and asymptomatic; severe thrombocytopenia (<20 × 10^9/L) suggests another diagnosis.

BASIC INFORMATION

DEFINITION

Normal blood pressure (BP) in adults can be defined as systolic BP <120 mm Hg and diastolic BP <80 mm Hg. Elevated blood pressure is defined as systolic BP between 120 and 129 mm Hg or diastolic BP <80 mm Hg. Hypertension can be divided into stage 1: systolic BP from 130 to 139 mm Hg or diastolic BP from 80 to 89 mm Hg and stage 2: systolic BP ≥140 mm Hg or diastolic BP ≥90 mm Hg. This definition is based on accurate measurements and average of ≥2 readings on ≥2 occasions.

SYNONYMS

Essential hypertension
Idiopathic hypertension
High BP

ICD-10CM CODES	
I10	Essential (primary) hypertension
I15.0	Renovascular hypertension
I15.1	Hypertension secondary to other renal disorders
I15.2	Hypertension secondary to endocrine disorders
I15.8	Other secondary hypertension
I15.9	Secondary hypertension, unspecified
O10.919	Unspecified pre-existing hypertension complicating pregnancy, unspecified trimester
I67.4	Hypertensive encephalopathy

EPIDEMIOLOGY & DEMOGRAPHICS

- In the U.S., 50% of people age 60 to 69 yr and approximately 75% of people >70 yr of age are affected. Worldwide, it is estimated that 41% of people ages 35 to 70 yr have hypertension, and only 46.5% of them are aware of it.
- Peak prevalence increases with age and is highest among non-Hispanic black adults in the U.S.
- Hypertension is linked with a higher risk of heart attack, stroke, heart failure, and kidney disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Physical examination may be entirely within normal limits except for the presence of elevated BP. A proper initial physical examination on a hypertensive patient should include the following:

- The BP should be measured with an appropriately sized cuff (bladder of the cuff should cover at least two thirds of the circumference of the arm) and in both arms (the higher of the readings being used). Table 1 describes blood pressure cuff size and error in measurement.
- The BP should be measured twice on each visit, and separated by at least 1 to 2 min to allow the return of trapped blood.
- The patient should be seated in a calm environment for at least 5 min with the arm in which BP is measured rested on support level with the heart.
- Postural BP change should always be recorded in the elderly to diagnose postural hypotension. This is assessed by taking BP in supine (after 5-min rest) and standing (after 2 min) positions. A drop of ≥20 mm Hg in systolic, a drop of ≥10 mm Hg diastolic BP, or symptoms of cerebral hypoperfusion is suggestive of postural (orthostatic) hypotension.
- A diagnosis of hypertension (HTN) may be established if the BP is markedly elevated (>180/110 mm Hg) or has evidence of end organ damage; otherwise such a diagnosis should wait until BP is found elevated on >2 readings on >2 different occasions.
- Nonoffice (home, workplace, 24-hr ambulatory) BP determination to establish the pattern of HTN (sustained, "white coat," or "masked" HTN) in selected patients.
- Measure heart rate, height, weight, body mass index, and waist circumference.
- Some general clinical clues for when to screen for secondary HTN include:
  1. Severe or resistant HTN
  2. An acute rise in BP developing in a patient with previous stable BP
  3. Age less than 30 yr, non-obese, non-black with no family history of HTN
  4. Sudden onset or accelerated hypertension
  5. Age of onset before puberty. If above is suspected, additional tests for secondary HTN should be done including renin, aldosterone, cortisol levels, 24-hr urine metanephrines, and serum catecholamines
- Physical examination should include searching for secondary causes, and sequelae of hypertension.
- Examine skin for the presence of café-au-lait spots (neurofibromatosis), uremic appearance (renal failure), and violaceous striae (Cushing syndrome).
- Perform careful funduscopic examination; check for papilledema, retinal exudates, hemorrhages, arterial narrowing, arteriovenous compression.
- Examine neck for carotid bruits, distended neck veins, and enlarged thyroid gland.
- Perform extensive cardiopulmonary examination: Check for a laterally displaced point of maximal intensity, an S3 or S4, and valvular murmurs.
- Palpate abdomen for renal masses (pheochromocytoma, polycystic kidneys), and auscultate for bruit over the aorta and renal arteries.
- Examine arterial pulses (dilated or absent femoral pulses and BP greater in upper extremities than lower extremities suggest aortic coarctation).
- Look for truncal obesity (Cushing syndrome) and pedal edema (congestive heart failure [CHF]).
- Table 2 provides a guide to evaluation of identifiable causes of HTN.
- Table 3 summarizes clinical clues to guide the investigation in young patients with hypertension that has a potentially hereditary cause.

ETIOLOGY

- Essential (primary) HTN (85%)
- Drug induced or drug related (5%)
  1. NSAIDs
  2. Oral contraceptives
  3. Corticosteroids
- Renal HTN (5%)
  1. Renal parenchymal disease (3%)
  2. Renovascular HTN (RVH) (<2%)
- Endocrine (<2%)
  1. Primary aldosteronism (at least 5%)
  2. Pheochromocytoma (0.2%)
  3. Cushing syndrome and long-term steroid therapy (0.2%)
  4. Hyperparathyroidism or thyroid disease (0.2%)
- Coarctation of the aorta (0.2%)

DIAGNOSIS

WORKUP

- The objective for the initial evaluation of HTN is to establish the diagnosis and stage of HTN. Table 4 summarizes initial laboratory evaluation of the hypertensive patient.
- Gather office and nonoffice BP readings, assess presence of target organ damage

TABLE 1 Blood Pressure Cuff Size and Error in Measurement*

	Arm Circumference		
Cuff Bladder Size	**28 cm or less**	**29-42 cm**	**43 cm or more**
Regular (12 × 23 cm)	Accurate	Overestimates SBP by 4-8 mm Hg DBP by 3-6 mm Hg	Overestimates SBP by 16-17 mm Hg DBP by 10-11 mm Hg
Large (15 × 33 cm)	Underestimates SBP by 2-3 mm Hg DBP by 1-2 mm Hg	Accurate	Overestimates SBP by 5-7 mm Hg DBP by 2-4 mm Hg
Thigh (18 × 36 cm)	Underestimates SBP by 5-7 mm Hg DBP by 1-3 mm Hg	Underestimates SBP by 5-7 mm Hg DBP by 2-4 mm Hg	Accurate

DBP, Diastolic blood pressure reading; *SBP,* systolic blood pressure reading.
**Overestimation* means that hypertension may be diagnosed in someone with normal blood pressure; *underestimation* means that the blood pressure reading may be normal in someone who actually has high blood pressure. See text for further discussion.
From McGee S: *Evidence-based physical diagnosis,* ed 4, Philadelphia, 2018, Elsevier.

TABLE 2 Guide to Evaluation of Identifiable Causes of Hypertension

Suspected Diagnosis	Clinical Clues	Diagnostic Testing
Chronic kidney disease	Estimated GFR <60 ml/min/1.73 m^2 Urine albumin-to-creatinine ratio ≥30 mg/g	Renal sonography
Renovascular disease	New elevation in serum creatinine, marked elevation in serum creatinine with ACEI or ARB, drug-resistant hypertension, flash pulmonary edema, abdominal, or flank bruit	Renal sonography (atrophic kidney), CT or MR angiography, invasive angiography
Coarctation of the aorta	Arm pulses > leg pulses, arm BP > leg BP, chest bruits, rib notching on chest radiography	MR angiography, TEE, invasive angiography
Primary aldosteronism	Hypokalemia, drug-resistant hypertension	Plasma renin and aldosterone, 24-hr urine aldosterone and potassium after oral salt loading, adrenal vein sampling
Cushing syndrome	Truncal obesity, wide and blanching purple striae, muscle weakness	1 mg dexamethasone-suppression test, urinary cortisol after dexamethasone, adrenal CT
Pheochromocytoma	Paroxysms of hypertension, palpitations, perspiration, and pallor; diabetes	Plasma metanephrines, 24-hr urinary metanephrines and catecholamines, abdominal CT or MR imaging
Obstructive sleep apnea	Loud snoring, large neck, obesity, somnolence	Polysomnography

ACEI, Angiotensin-converting enzyme inhibitor; *ARB,* angiotensin receptor blocker; *BP,* blood pressure; *CT,* computed tomography; *GFR,* glomerular filtration rate; *MR,* magnetic resonance; *TEE,* transesophageal echocardiography.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.

TABLE 3 Clinical Clues to Guide the Investigation in Young Patients with Hypertension That Has a Potentially Hereditary Cause

Specific Conditions	Possible Causes of Familial Hypertension	Clinical Clues
Catecholamine-Producing Tumors		
Pheochromocytoma/paraganglioma	Familial cases are responsible for <30% of cases, including MEN2A and MEN2B, von Hippel-Lindau disease, neurofibromatosis, and familial paraganglioma syndromes (SDH complex mutations)	Paroxysmal palpitations, headaches, diaphoresis, pale flushing; syndromic features of any of the associated disorders
Neuroblastomas (adrenal) Aortic or renovascular lesions	1%-2% of neuroblastomas are familial	
Coarctation of the aorta	Overrepresented in families but no familial distribution	Asymmetry between upper- and lower-extremity BP, radial-formal pulse delay; associated with Turner syndrome, Williams syndrome, and bicuspid aortic valve
Renal artery stenosis caused by fibromuscular dysplasia or inherited arterial wall lesions	<10% familial with AD pattern	Abnormal renal vascular imaging results; vascular disease in the carotid territory at an early age; common in neurofibromatosis and Williams syndrome; also present in tuberous sclerosis, Ehlers-Danlos syndrome, and Marfan syndrome
Parenchymal kidney disease GN	Alport disease (X-linked, AR, or AD), familial IgA nephropathy (AD with incomplete penetrance)	Proteinuria, hematuria, low eGFR
PKD	ADPKD type 1 or 2, ARPKD	Multiple renal cysts (as few as three in patients under 30 yr)
Adrenocortical disease Glucocorticoid-remediable aldosteronism (familial hyperaldosteronism type I)	AD chimeric fusion of the 11β-hydroxylase and aldosterone synthase genes	Cerebral hemorrhages at young age, cerebral aneurysms; mild hypokalemia; high plasma aldosterone, low renin
Familial hyperaldosteronism	AD; unknown defect	Severe type 2 hypertension in early adulthood; high plasma aldosterone, low renin; no response to glucocorticoid treatment
Familial hyperaldosteronism type III	AD; unknown defect	Severe hypertension in childhood with extensive target-organ damage; high plasma aldosterone, low renin; marked bilateral adrenal enlargement
Congenital adrenal hyperplasia	AR mutations in 11β-hydroxylase or 21-hydroxylase	Hirsutism, virilization; hypokalemia and metabolic alkalosis; low plasma aldosterone and renin
Monogenic Primary Renal Tubular Defects		
Gordon syndrome	AD mutations of *KLHL3, CUL3, WNK1,* and *WNK4;* AR mutations of *KLHL3*	Hyperkalemia and metabolic acidosis with normal renal function
Liddle syndrome	AD mutations of the epithelial sodium channel	Hypokalemia and metabolic alkalosis; low plasma aldosterone and renin
Apparent mineralocorticoid excess	AD mutation in 11β-hydroxysteroid dehydrogenase type 2	Hypokalemia and metabolic alkalosis; low plasma aldosterone and renin
Geller syndrome Hypertension-brachydactyly syndrome	AD mutation in the mineralocorticoid receptor AD mutations in the phosphodiesterase E3A enzyme	Hypokalemia and metabolic alkalosis; low plasma aldosterone and renin; increased BP during pregnancy or exposure to spironolactone
Unknown Mechanisms		
Hypertension-brachydactyly syndrome	AD	Short fingers (small phalanges) and short stature; brainstem compression from vascular tortuosity in the posterior fossa
Essential Hypertension		
	Polygenic	When obesity or metabolic syndrome is present, the likelihood of essential hypertension is higher

AD, Autosomal dominant; *ADPKD,* autosomal dominant polycystic kidney disease; *AR,* autosomal recessive; *ARPKD,* autosomal recessive polycystic kidney disease; *BP,* blood pressure; *eGFR,* estimated glomerular filtration rate; *GN,* glomerulonephritis; *IgA,* immunoglobulin A; *MEN,* multiple endocrine neoplasia; *PKD,* polycystic kidney disease; *SDH,* succinate dehydrogenase.
From Skorecki K et al: *Brenner and Rector's the kidney,* ed 10, Philadelphia, 2016, Elsevier.

TABLE 4 Initial Laboratory Evaluation of the Hypertensive Patient to Investigate the Presence of Comorbid Conditions, Secondary Causes, or Established Target-Organ Damage

Test	Clinical Usefulness
Serum creatinine (and estimated glomerular filtration rate)	Assessment of renal function. Identifies parenchymal kidney disease as a possible secondary cause as well as established TOD.
Serum potassium	Low potassium (of renal origin) suggests mineralocorticoid excess (primary or secondary), glucocorticoid excess, Liddle syndrome. High potassium with normal renal function suggests Gordon syndrome. Low levels raise caution about the use of thiazides and loop diuretics. High levels preclude the use of ACEIs, ARBs, renin inhibitors, and potassium-sparing diuretics.
Serum sodium	If high, suggests primary aldosteronism. If low, alerts to the need to avoid thiazide diuretics.
Serum bicarbonate	If high, suggests aldosterone excess (primary or secondary). If low with normal renal function, suggests Gordon syndrome (with high potassium) or primary hyperparathyroidism (with high calcium).
Serum calcium	If high, suggests primary hyperparathyroidism.
Serum glucose	Identifies prediabetes or diabetes. In the appropriate setting, suggests glucocorticoid excess, pheochromocytoma, or acromegaly.
Lipid profile	Identifies hyperlipidemia.
Hemoglobin/hematocrit	If high, in the absence of other hematologic abnormalities or underlying lung disease, suggests sleep apnea.
Urinalysis*	Proteinuria and hematuria identify a possible secondary cause (glomerulonephritis). Proteinuria can also be a marker of TOD.
Electrocardiogram	Identifies left ventricular hypertrophy, old myocardial infarction, or other ischemic changes. Identifies conduction abnormalities that may preclude the use of β-blockers or nondihydropyridine CCBs.

The most recent guidelines do not recommend blood urea nitrogen (BUN) measurement alone.
*Some organizations recommend screening microalbuminuria as a more sensitive tool to identify early renal injury.
ACEI, Angiotensin-converting enzyme inhibitor; *ARB,* angiotensin receptor blocker; *CCB,* calcium channel blocker; *TOD,* target-organ damage.
From Skorecki K et al: *Brenner and Rector's the kidney,* ed 10, Philadelphia, 2016, Elsevier.

(TOD), assess the level of global cardiovascular disease risk, and produce a plan for individualized monitoring and therapy
- Patient counseling and education should be prominent features of the initial evaluation
- Pertinent history:
  1. Age of onset of HTN, previous antihypertensive therapy
  2. Family history of HTN, stroke, cardiovascular disease
- Diet, salt intake, caffeine, alcohol, drugs (e.g., oral contraceptives, NSAIDs, decongestants, steroids)
- Occupation, lifestyle, pain, socioeconomic status, psychologic factors
- Other cardiovascular risk factors: Hyperlipidemia, obesity, diabetes mellitus
- Symptoms of secondary HTN:
  1. Headache, palpitations, excessive perspiration (possible pheochromocytoma)
  2. Weakness, polyuria (consider hyperaldosteronism)
  3. Claudication of lower extremities (seen with coarctation of aorta)
  4. Loud snoring, daytime somnolence, morning confusion (may warrant evaluation for sleep apnea)

LABORATORY TESTS

- Routine laboratory tests recommended before initiating therapy include:
  1. Urinalysis with microscopic evaluation; for signs of glomerulopathy
  2. Basic metabolic panel and calcium; for signs of kidney damage, hypokalemia (primary aldosteronism and Cushing syndrome), hypercalcemia (hyperparathyroid)
  3. Complete blood count
  4. Screening for coexisting diseases that may adversely affect prognosis; hemoglobin A1c or fasting glucose level, serum lipid panel
  5. Optional tests include measurement of urinary albumin or albumin/creatinine ratio

IMAGING STUDIES

- ECG: Check for presence of left ventricular hypertrophy (LVH) with strain pattern.
- Renal duplex ultrasonography, CT angiography or magnetic resonance angiography of the renal arteries in suspected renovascular hypertension (renal artery stenosis) may be considered.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Lifestyle modifications (the initial treatment of hypertension should focus on lifestyle modifications):
- Weight loss if overweight (target body mass index [BMI] <25).
- Limit alcohol intake to 1 oz of ethanol per day (<2 drinks/day) in men or 0.5 oz (<1 drink/day) in women.
- Regular aerobic exercise (at least 30 min/day on most days).
- Reduce sodium intake to <100 mmol/day (<1.5 g of sodium/day).
- Maintain adequate dietary potassium (>3500 mg/day) intake in patients with normal kidney function.
- Smoking cessation.
- The BP reduction seen ranges from 2 to 20 mm Hg, most significant with substantial weight loss and the implementation of the Dietary Approaches to Stop Hypertension (DASH) eating plan, which relies on a diet high in fruits and vegetables, moderate in low-fat dairy products, and low in animal protein but with substantial amount of plant protein from legumes and nuts.

ACUTE GENERAL Rx

- Multiple recent consensus documents regarding blood pressure goals and when to initiate treatment have been published.
- According to the 2017 *ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCNA Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults*, goals of treatment are as follows[1]:
  1. For adults with confirmed hypertension and known cardiovascular disease (CVD) or 10-yr atherosclerotic cardiovascular disease (ASCVD) event risk of 10% or higher, a BP target of less than 130/80 mm Hg is recommended.
  2. For adults with confirmed hypertension without additional markers of increased CVD risk, a BP target of less than 130/80 mm Hg may be reasonable.
- In addition, initiation of therapy recommendations is as follows:
  1. Use of BP-lowering medication is recommended for primary prevention of CVD in adults with no history of CVD and with an estimated 10-yr ASCVD risk <10% and stage 2 hypertension.
  2. Use of BP-lowering medications is recommended for secondary prevention of recurrent CVD events in patients with clinical CVD and for primary prevention in adults with an estimated 10-yr ASCVD risk of 10% or higher and stage 1 hypertension.
  3. Initiate antihypertensive drug therapy with two first-line agents of different classes for adults with stage 2 hypertension and BP more than 20/10 mm Hg higher than their target.
  4. It is reasonable to initiate therapy with a single agent for adults with stage 1 hypertension and a goal less than 130/80 mm Hg.

[1]Whelton P et al: 2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCNA Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults executive summary: a report of the American College of Cardiology/American Heart Association task force on clinical guidelines, *J Am Coll Cardiol* 2017.

5. Patients with diabetes mellitus and chronic kidney disease are considered high risk.

- Additional guidance may be taken from the writers of the JNC 8 guidelines, published in 2014[2]:
  1. In the general non-black population, preferred initial agents are thiazide-type diuretics, angiotensin-converting enzyme inhibitors (ACEI), calcium channel blockers (CCBs), or angiotensin receptor blockers (ARBs). ACEI or ARBs are preferred initial agents in diabetics and those with chronic kidney disease (CKD) in this population.
  2. Preferred initial agents in the black population (including diabetics) are thiazide-type diuretics or CCBs.
  3. When selecting drugs, try to give once per day dosages to improve compliance. Also consider the cost of the medication, metabolic and subjective side effects, and drug-drug interactions.
- The major advantages and limitations of each class of drugs are described as follows:
  1. Thiazide diuretics:
     a. Advantages: Inexpensive, once-daily dosing. Useful in edematous states, CHF, chronic renal disease, elderly patients (decreased incidence of hip fractures in elderly patients)
     b. Disadvantages: Significant adverse metabolic effects (hypokalemia), increased risk of cardiac arrhythmias, sexual dysfunction, gout flares, possible adverse effects on lipids and glucose levels
  2. Beta-blockers:
     a. Advantages: Ideal in hypertensive patients with ischemic heart disease or status post myocardial infarction (MI); favored in hyperkinetic, young patients (resting tachycardia, wide pulse pressure, hyperdynamic heart) and stable CHF patients
     b. Disadvantages: Adverse effect on quality of life (increased incidence of fatigue, depression, impotence), bronchospasm, hypoglycemia, peripheral vascular disease, adverse effects on lipids, masking of signs and symptoms of hypoglycemia in diabetics
  3. Calcium antagonists:
     a. Advantages: Helpful in hypertensive patients with ischemic heart disease. Generally favorable effect on quality of life; can be used in patients with bronchospastic disorders, renal disease, peripheral vascular disease, metabolic disorders, and salt sensitivity. CCBs BP-lowering effect is independent of Na^+ intake.
     b. Disadvantages: Diltiazem and verapamil should be avoided in patients with CHF due to systolic dysfunction because of their negative inotropic effects; pedal edema may occur with nifedipine and amlodipine; constipation can be severe in elderly patients receiving verapamil. CCB-related edema is positional in nature, it improves with lying position; additional strategies include switching CCB classes, reducing dosage, giving the medication later in the day, and adding a venodilator (nitrates, an ACE, or an ARB); diuretics may improve edema, but at the expense of a reduction in plasma volume.
  4. ACE inhibitors:
     a. Advantages: First-line therapy for patients with left ventricular dysfunction, helpful in prevention of diabetic renal disease; effective in decreasing LVH, and remodeling.
     b. Disadvantages: Dry cough is a frequent side effect (5% to 20% of patients); hyperkalemia may occur in patients with diabetes or severe renal insufficiency; hypotension may occur in volume-depleted patients; increased risk of renal failure in patients with renal artery stenosis; contraindicated in pregnancy.
  5. ARBs:
     a. Advantages: Well tolerated, favorable impact on quality of life; useful in patients unable to tolerate ACE inhibitors because of persistent cough and in CHF and diabetic patients; single daily dose. An episode of renal insufficiency with ACE inhibitors does not rule out future therapy with an ARB unless high-grade bilateral renal artery stenosis exists.
     b. Disadvantages: Hypotension may occur in volume-depleted patients; hyperkalemia; risk of renal failure in renal artery stenosis; contraindicated in pregnancy.
  6. Alpha-adrenergic blockers:
     a. Advantages: No adverse effect on blood lipids or insulin sensitivity; helpful in benign prostatic hypertrophy.
     b. Disadvantages: Postural hypotension, sedation; syncope can be avoided by giving an initial low dose at bedtime. Generally considered third- or fourth-line agent.
  7. Central alpha-antagonists:
     a. Oral clonidine mainstay of therapy for hypertensive urgencies because of the ease of administration and relative safety.
     b. Transdermal clonidine; useful in management of labile HTN, the hospitalized patient who cannot take medications by mouth, and patients subject to early-morning BP surges. At equivalent doses, transdermal clonidine is more apt to precipitate salt and water retention than is the case with oral clonidine.
     c. Dose beyond 0.4 mg causes fatigue, sedation, dry mouth, salt and water retention, and rebound HTN upon abrupt termination of the medication.
  8. Combined alpha- and beta-adrenergic receptor blockers:
     a. Labetalol, nebivolol, and carvedilol: Use is reserved to treat complicated hypertensive patient when an antihypertensive effect beyond beta-blockade is sought. IV labetalol is used for hypertensive emergencies. Carvedilol is shown to have less adverse effect on glycemic control than metoprolol and to reduce urinary protein excretion in hypertensive diabetic patients.
  9. Direct-acting smooth muscle relaxant: Hydralazine
     a. Advantages: Beneficial in black patients when used with isosorbide dinitrate.
     b. Disadvantages: May lead to reflex tachycardia, worsening ischemia (best used with nitrates), at higher doses or with renal failure can lead to a reversible drug-induced lupus.
  10. Renin inhibitors: Newest class of antihypertensives (Aliskiren):
      a. Advantages: Generally well tolerated; once-daily dosing; can be used alone or in combination with other antihypertensive agents (avoid combining with ACEI or ARBs given increase of hyperkalemia).
      b. Disadvantages: Contraindicated in pregnancy; should not be used in patients with impaired renal function; excessive cost; paucity of cardiovascular outcomes data showing benefit.

TREATMENT OF RENOVASCULAR HYPERTENSION: The therapeutic approach varies with the cause of the renovascular hypertension (RVH) (refer to "Renal Artery Stenosis" for additional information).

- Young patients with fibromuscular dysplasia refractory to medical therapy can be treated with percutaneous transluminal renal angioplasty (PTRA).
- Medical therapy is advisable in elderly patients with atheromatous RVH; useful agents are:
  1. Beta-blockers: Highly effective in patients with elevated plasma renin
  2. ACE inhibitors: Highly effective; however, should be avoided in patients with bilateral renal artery stenosis or with a solitary kidney and renal artery stenosis
  3. Diuretics: Often used in combination with ACE inhibitors
- Surgical revascularization: A recent trial revealed that renal-artery stenting does not confer a significant benefit with respect to the prevention of clinical events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal-artery stenosis and hypertension or CKD.[3]

[2]James PA et al: 2014 Evidence-based guidelines for the management of high blood pressure in adults. Report from the panel members appointed to the eighth Joint National Committee (JNC8), *JAMA* 311(5):507-520, 2014.

TABLE 5 Drugs Used to Treat Hypertension in Pregnancy

Drug	Starting Dose	Maximum Dose	Comments
Acute Treatment of Severe Hypertension			
Hydralazine	5-10 mg IV every 20 min	20 mg*	Avoid in cases of tachycardia and persistent headaches
Labetalol	20-40 mg IV every 10-15 min	220 mg*	Avoid in women with asthma or congestive heart failure
Nifedipine	10-20 mg oral every 30 min	50 mg*	Avoid in case of tachycardia and palpitations
Long-Term Treatment of Hypertension			
Methyldopa	250 mg bid	4 g/day	
Labetalol	100 mg bid	2400 mg/day	
Nifedipine	10 mg bid	120 mg/day	
Thiazide diuretic	12.5 mg bid	50 mg/day	

*If desired blood pressure levels are not achieved, switch to another drug.
From Gabbe SG: *Obstetrics,* ed 6, Philadelphia, 2012, WB Saunders.

HTN DURING PREGNANCY:
- HTN complicates 5% to 12% of all pregnancies.
- The American Obstetrical Committee defines BP of 130/80 mm Hg as the upper limit of normal at any time during pregnancy.
- A rise of 30 mm Hg systolic or 15 mm Hg diastolic is also considered abnormal regardless of the absolute values obtained.
- Hypertension during pregnancy can be from chronic HTN, gestational HTN, preeclampsia or preeclampsia superimposed on chronic HTN. It is important to distinguish the etiology because the risk to mother and fetus is much greater in preeclampsia.
- Treatment of chronic HTN during pregnancy is as follows:
  1. Initial treatment with conservative measures (proper nutrition, limited physical activity).
  2. When drug therapy is necessary, initiation of methyldopa, hydralazine, labetalol or nifedipine is preferred. Table 5 summarizes drugs used to treat hypertension in pregnancy.
  3. ACE inhibitors can cause fetal and neonatal complications; their use should be avoided in pregnancy.
  4. The safety of CCBs remains unclear.
  5. Diuretics should be used only if there is a specific reason for initiating and maintaining their use (e.g., HTN associated with severe fluid overload or left ventricular dysfunction).

MALIGNANT HTN, HYPERTENSIVE EMERGENCIES, AND HYPERTENSIVE URGENCIES: Definitions:
- Malignant HTN occurs with HTN when there are grades III and IV retinopathy (exudates, hemorrhages, and papilledema).
  1. The rate of BP rise is a critical factor in the development of malignant HTN.
  2. Complications and mortality rates are much higher in malignant HTN compared with essential HTN.
  3. Requires immediate BP reduction (not necessarily into normal ranges) to prevent or limit target organ disease.
- Hypertensive emergencies occur when the BP elevation is >180 mm Hg systolic and/or >120 mm Hg diastolic without evidence of new or progressive organ dysfunction. It requires rapid lowering of BP to prevent end-organ damage.
- Hypertensive urgencies are BP elevations >180 mm Hg systolic and/or >120 mm Hg diastolic with end-organ damage that should be corrected within 24 hr of presentation.
  1. Most clinicians suggest lowering the BP to <160 mm Hg/<100 mm Hg or to a level no more than 30% lower than the patient's baseline BP.

Therapy: The choice of therapeutic agents varies with the cause. IV medications are preferred in hypertensive emergencies.
- Nitroprusside is the drug of choice in hypertensive encephalopathy, HTN and intracranial bleeding, malignant HTN, HTN and heart failure, dissecting aortic aneurysm (used in combination with propranolol); its onset of action is immediate. Because it is metabolized to cyanide, patients should be carefully monitored for toxicity (mental status changes, acidemia).
- Fenoldopam is a vasodilator agent useful for the short-term (up to 48 hr) management of severe HTN when rapid but quickly reversible reduction of BP is required. It should be avoided in patients with glaucoma.
- Other commonly used agents are the IV CCBs nicardipine and clevidipine (useful for urgent treatment of HTN in the intensive care unit or operating room), the beta-blocker esmolol (useful in aortic dissection or postoperative HTN), labetalol (combined β-adrenergic and α-blocker useful in patients with coronary disease), phentolamine (useful for catecholamine-related emergencies), IV nitroglycerin (used in patients with cardiac ischemia and hypertensive crisis), and hydralazine (used for hypertensive emergencies in pregnancy.
- Table 6 summarizes IV medications useful in hypertensive crisis.

The following are important points to remember when treating hypertensive emergencies:
- Introduce a plan for long-term therapy at the time of the initial emergency treatment.
- Agents that reduce arterial pressure can cause the kidney to retain sodium and water; therefore, the judicious administration of diuretics should accompany their use.
- The initial goal of antihypertensive therapy is not to achieve a normal BP, but rather to gradually reduce the BP; cerebral hypoperfusion may occur if the mean BP is hypertension in patients with CKD.

PEARLS & CONSIDERATIONS

COMMENTS
- "Masked hypertension" refers to the detection of hypertension with home or ambulatory monitoring. Up to 40% of patients with BP less than 140/90 mm Hg in the office may have masked hypertension. Automated blood pressure monitors are useful to screen for masked hypertension.
- "White coat hypertension" is defined as an elevated BP during medical office exam with BP in the normal range at home. Its prevalence is as high as 30% among patients with an elevated BP in the office. These patients are at increased risk for overt hypertension.
- For patients with hypertension, every 20/10 mm Hg increase in BP doubles the risk of cardiovascular events.
- Most patients will require at least two medications for BP control.
- If BP is greater than 20/10 mm Hg above goal, therapy should be initiated with two drugs.
- Resistant HTN: HTN is considered resistant if the BP cannot be reduced below target levels in patients who are compliant with an optimal triple-drug regimen that includes a diuretic. Terms *refractory* and *resistant* are used interchangeably. Causes include pseudohypertension, measurement artifact, medication nonadherence, volume overload, and secondary HTN.
  1. Pseudohypertension in elderly: Hardened and sclerotic artery is not compressible hence falsely elevates BP measurement artifact.
  2. Measurement artifact: BP taken incorrectly (small cuff, improper support).
- Renal sympathetic denervation: A recent blinded trial did not show a significant reduction of systolic blood pressure in patients with resistant hypertension 6 mo after renal artery denervation as compared with a sham control.
- Barriers to BP control: System issues, provider issues; patient issues, and behavior issues. The rate at which physicians adopt recommended changes based on evidence-based findings can be quite slow and has been properly described as "clinical inertia."
- Indications for specialist referral for patients with HTN are described in Table 7.
- New U.S. guidelines for the treatment of hypertension recommend the following:
  1. Use of blood pressure-lowering medication for secondary prevention in patients with cardiovascular disease and average systolic blood pressure (SBP) ≥130 mm

TABLE 6 Treatment of Hypertensive Crisis: Intravenous Medications

Drug Name and Mechanism of Action	Indications/Advantages/Dose	Disadvantages/Adverse Effects/Metabolism Cautions
Sodium Nitroprusside		
Nitric oxide compound; vasodilation of arteriolar and venous smooth muscle Increases cardiac output by decreasing afterload	Useful in most hypertensive emergencies Onset of action immediate, duration of action 1-2 min Dose: 0.25 μg/kg/min Maximum dose: 8-10 μg/kg/min	Contraindicated in high-output cardiac failure, congenital optic atrophy. Anemia and liver disease at risk of cyanide toxicity: Acidosis, tachycardia, change in mental status, almond smell on breath. Risk of thiocyanate toxicity with renal disease: Psychosis, hyperreflexia, seizure, tinnitus. Cautious use with increased intracranial pressure. Do not use maximum dose for more than 10 min. Crosses the placenta.
Nitroglycerin		
Directly interacts with nitrate receptors on vascular smooth muscle Primarily dilates venous bed Decreases preload	Use with symptoms of cardiac ischemia, perioperative hypertension in cardiac surgery Initial dose: 5 μg/min Maximum dose: 100 μg/min	Contraindicated in angle-closure glaucoma, increased intracranial pressure. Blood pressure decreased secondary to decreased preload, cardiac output—avoid when cerebral or renal perfusion compromised. Caution with right ventricular infarct.
Labetalol		
β- and α-Adrenergic blockade α:β-Blocking ratio is 1:7	Onset of action 2-5 min, duration 3-6 hr Bolus 20 mg, then 20-80 mg every 10 min for maximum dose 300 mg Infuse at 0.5-2 mg/min	Avoid in bronchospasm, bradycardia, congestive heart failure, greater than first-degree heart block, second/third trimester pregnancy. Use caution with hepatic dysfunction, inhalational anesthetics (myocardial depression). Enters breast milk.
Esmolol		
Cardioselective β1-adrenergic blocking agent	Use with aortic dissection Use during intubation, intraoperative, and postoperative hypertension Onset of action 60 sec, duration 10-20 min, 200-500 μg/kg/min for 4 min, then infuse 50-300 μg/kg/min	See labetalol. Not dependent on renal or hepatic function for metabolism (metabolized by hydrolysis in red blood cells).
Fenoldopam		
Postsynaptic dopamine-1 agonist; decreases peripheral vascular resistance; 10 times more potent than dopamine as vasodilator	May be advantageous in kidney disease, increases renal blood flow, increases sodium excretion, no toxic metabolites Initial dose: 0.1 μg/kg/min, with titration every 15 min No bolus	Contraindicated in glaucoma (may increase intraocular pressure) or allergy to sulfites; hypotension, especially with concurrent β-blocker. Check serum potassium every 6 hr. Concurrent acetaminophen may significantly increase blood levels. Dose-related tachycardia.
Hydralazine		
Primarily dilates arteriolar vasculature	Primarily used in pregnancy/eclampsia Dose: 10 mg every 20-130 min; maximum dose 20 mg Decreases blood pressure in 10-20 min Duration of action 2-4 hr	Reflex tachycardia; give β-blocker concurrently. May exacerbate angina. Half-life 3 hr, affects blood pressure for 100 hr. Depends on hepatic acetylation for inactivation.
Phentolamine		
α-Adrenergic blockade	Used primarily to treat hypertension from excessive catecholamine excess (e.g., pheochromocytoma) Dose: 5-15 mg Onset of action 1-2 min, duration 3-10 min	β-Blockade is generally added to control tachycardia or arrhythmias. As in all catecholamine excess states, β-blockers should never be given first, as the loss of β-adrenergically mediated vasodilatation will leave α-adrenergically mediated vasoconstriction unopposed and result in increased pressure.
Nicardipine		
Dihydropyridine calcium channel blocker; inhibits transmembrane influx of calcium ions into cardiac and smooth muscle	Onset of action 10-20 min, duration 1-4 hr Initial dose: 5 mg/hr to maximum of 15 mg/hr	Avoid with congestive heart failure, cardiac ischemia. Adverse effects include tachycardia, flushing, headache.
Clevidipine		
Short-acting dihydropyridine calcium channel antagonist	Initial dose: 1 mg/hr; can be increased to 21 mg/hr	Reduces blood pressure without affecting cardiac filling pressures or causing reflex tachycardia.
Enalaprilat		
Angiotensin-converting enzyme inhibitor	Onset of action 15-20 min, duration 12-24 hr Dose: 1.25-5 mg every 6 hr	Response not predictable, with high renin states may see acute hypotension. Hyperkalemia in setting of reduced glomerular filtration rate. Avoid in pregnancy.
Trimethaphan		
Nondepolarizing ganglionic blocking agent; competes with acetylcholine for postsynaptic receptors	Used in aortic dissection Dose: 0.5-5 mg/min	Does not increase cardiac output. No inotropic cardiac effect. Disadvantages include parasympathetic blockade, resulting in paralytic ileus and bladder atony and development of tachyphylaxis after 24-96 hr of use.

From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.

TABLE 7 Indications for Specialist Referral for Patients with Hypertension

Urgent Treatment Needed
Accelerated hypertension (severe hypertension with grade III-IV retinopathy)
Particularly severe hypertension (>220/120 mm Hg)
Impending complications (e.g., transient ischemic attack, left ventricular failure)
Possible Underlying Cause
Any clue in history or examination of a secondary cause (e.g., hypokalemia with increased or high–normal plasma sodium)
Elevated serum creatinine
Proteinuria or hematuria
Sudden onset or worsening of hypertension
Young age (any hypertension <20 yr; needing treatment <30 yr)
Therapeutic Problems
Multiple drug intolerances
Multiple drug contraindications
Persistent nonadherence or nonconcordance
Special Situations
Unusual blood pressure variability
Possible white coat hypertension
Hypertension in pregnancy

From Floege J et al: *Comprehensive clinical nephrology,* ed 4, Philadelphia, 2010, WB Saunders.

Hg or diastolic blood pressure (DBP) ≥80 mm Hg, and for primary prevention in adults with an estimated 10-yr ASCVD risk of >10% and an average SBP ≥130 mm Hg or DBP ≥80 mm Hg.

2. In patients with no history of cardiovascular disease and an estimated 10-yr ASCVD risk <10%, blood pressure lowering medication is recommended for those with an average SBP ≥140 mm Hg or an average DBP ≥90 mm Hg.

BASIC INFORMATION

DEFINITION

Hyperthyroidism is a hypermetabolic state resulting from excess thyroid hormone.

SYNONYM

Thyrotoxicosis

ICD-10CM CODES

E05.00	Thyrotoxicosis with diffuse goiter without thyrotoxic crisis or storm
E05.01	Thyrotoxicosis with diffuse goiter with thyrotoxic crisis or storm
E05.10	Thyrotoxicosis with toxic single thyroid nodule without thyrotoxic crisis or storm
E05.11	Thyrotoxicosis with toxic single thyroid nodule with thyrotoxic crisis or storm
E05.20	Thyrotoxicosis with toxic multinodular goiter without thyrotoxic crisis or storm
E05.21	Thyrotoxicosis with toxic multinodular goiter with thyrotoxic crisis or storm
E05.30	Thyrotoxicosis from ectopic thyroid tissue without thyrotoxic crisis or storm
E05.31	Thyrotoxicosis from ectopic thyroid tissue with thyrotoxic crisis or storm
E05.40	Thyrotoxicosis factitia without thyrotoxic crisis or storm
E05.41	Thyrotoxicosis factitia with thyrotoxic crisis or storm
E05.80	Other thyrotoxicosis without thyrotoxic crisis or storm
E05.81	Other thyrotoxicosis with thyrotoxic crisis or storm
E05.90	Thyrotoxicosis, unspecified without thyrotoxic crisis or storm
E05.91	Thyrotoxicosis, unspecified with thyrotoxic crisis or storm
E06.2	Chronic thyroiditis with transient thyrotoxicosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE/PREVALENCE:

- Hyperthyroidism affects 2% of women and 0.2% of men in their lifetimes.
- Toxic multinodular goiter usually occurs in women >55 yr and is more common than Graves disease in the elderly.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with hyperthyroidism generally present with tachycardia, tremor, hyperreflexia, anxiety, irritability, emotional lability, panic attacks, heat intolerance, sweating, increased appetite, diarrhea, weight loss, menstrual dysfunction (oligomenorrhea, amenorrhea). Presentation may be different in elderly patients (see the following).
- Patients with Graves disease may present with exophthalmos, lid retraction, and lid lag (Graves ophthalmopathy). The following signs and symptoms of ophthalmopathy may be present: blurring of vision, photophobia, increased lacrimation, double vision, and deep orbital pressure. Clubbing of fingers associated with periosteal new bone formation in other skeletal areas (Graves acropachy) and pretibial myxedema may also be noted.
- Clinical signs of hyperthyroidism in the elderly may be masked by manifestations of coexisting disease (e.g., new-onset atrial fibrillation, exacerbation of congestive heart failure).

ETIOLOGY

- Graves disease (diffuse toxic goiter): 80% to 90% of all cases of hyperthyroidism
- Toxic multinodular goiter (Plummer disease)
- Toxic adenoma
- Iatrogenic and factitious
- Transient hyperthyroidism (subacute thyroiditis, Hashimoto thyroiditis)
- Rare causes: Hypersecretion of thyroid-stimulating hormone (TSH) (e.g., pituitary neoplasms), struma ovarii, ingestion of large amount of iodine in a patient with preexisting thyroid hyperplasia or adenoma (Jod-Basedow phenomenon), hydatidiform mole, carcinoma of thyroid, amiodarone therapy

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Anxiety disorder
- Pheochromocytoma
- Metastatic neoplasm
- Diabetes mellitus
- Premenopausal state

WORKUP

Suspected hyperthyroidism requires laboratory confirmation and identification of its etiology because treatment varies with cause. A detailed medical history will often provide clues to the diagnosis and etiology of the hyperthyroidism. Fig. E1 describes a diagnostic approach to suspected hyperthyroidism.

LABORATORY TESTS

- Elevated free thyroxine (T_4)
- Elevated free triiodothyronine (T_3): Generally not necessary for diagnosis
- Low TSH (unless hyperthyroidism is a result of the rare hypersecretion of TSH from a pituitary adenoma)
- Thyroid autoantibodies useful in selected cases to differentiate Graves disease from toxic multinodular goiter (absent thyroid antibodies)

IMAGING STUDIES

- 24-hour radioactive iodine uptake (RAIU) is useful to distinguish hyperthyroidism from iatrogenic thyroid hormone synthesis (thyrotoxicosis factitia) and from thyroiditis.
- An overactive thyroid shows increased uptake, whereas a normal underactive thyroid (iatrogenic thyroid ingestion, painless or subacute thyroiditis) shows normal or decreased uptake.
- The RAIU results also vary with the etiology of the hyperthyroidism:
  1. Graves disease: Increased homogeneous uptake
  2. Multinodular goiter: Increased heterogeneous uptake
  3. Hot nodule: Single focus of increased uptake
- RAIU is also generally performed before the therapeutic administration of radioactive iodine to determine the appropriate dose.

TREATMENT

NONPHARMACOLOGIC THERAPY

Patient education regarding thyroid disease and discussion of the therapeutic options. Patients should be informed that radioiodine, antithyroid drugs, and surgery are all reasonable treatment options for hyperthyroidism. It is crucial for the physician to have a detailed discussion with the patient about the benefits and risks relative to lifestyle, patients' values, and coexisting conditions.

ACUTE GENERAL Rx

ANTITHYROID DRUGS (THIONAMIDES): Propylthiouracil (PTU) and methimazole inhibit thyroid hormone synthesis by blocking production of thyroid peroxidase (PTU and methimazole) or inhibit peripheral conversion of T_4 to T_3 (PTU). Methimazole is favored by most endocrinologists because of the potential for hepatic failure with PTU. PTU is preferred in pregnant women during the first trimester because methimazole has been associated with aplasia cutis and with choanal and esophageal atresia. Complete blood count and differential should be obtained before their use.

- Dosage: Methimazole 15 to 30 mg/day given as a single dose; PTU 50 to 100 mg PO q8h.
- Antithyroid drugs can be used as the primary form of treatment or as adjunctive therapy before radioactive therapy or surgery or afterward if the hyperthyroidism recurs.
- Side effects: Skin rash (3% to 5% of patients), arthralgias, myalgias, granulocytopenia (0.5%). Rare side effects are aplastic anemia, hepatic necrosis from PTU, cholestatic jaundice from methimazole.
- When antithyroid drugs are used as primary therapy, they are usually given for 6 to 18 mo; prolonged therapy may cause hypothyroidism. Monitor thyroid function every 2 mo for 6 mo, then less frequently.
- The use of antithyroid drugs before radioiodine therapy is best reserved for patients in whom exacerbation of hyperthyroidism after radioactive iodine therapy is hazardous (e.g., elderly patients with coronary artery disease or significant coexisting morbidity). In these patients the antithyroid drug can be stopped 2 days before radioactive iodine therapy, resumed 2 days later, and continued for 4 to 6 wk.

RADIOIODINE THERAPY (RADIOACTIVE IODINE [RAI; ^{131}I]):
- RAI is the treatment of choice for patients aged >21 yr and younger patients who have not achieved remission after 1 yr of antithyroid drug therapy. RAI is also used in hyperthyroidism caused by toxic adenoma or toxic multinodular goiter.
- Contraindicated during pregnancy (can cause fetal hypothyroidism) and lactation. Pregnancy should be excluded in women of childbearing age before RAI is administered.
- A single dose of RAI is effective in inducing a euthyroid state in nearly 80% of patients.
- There is a high incidence of post-RAI hypothyroidism (>50% within first yr and 2%/yr thereafter); these patients should be frequently evaluated for the onset of hypothyroidism (see "Chronic Rx").

SURGICAL THERAPY (SUBTOTAL THYROIDECTOMY):
- Indicated in obstructing goiters, in any patient who refuses RAI and cannot be adequately managed with antithyroid medications (e.g., patients with toxic adenoma or toxic multinodular goiter), and in pregnant patients who cannot be adequately managed with antithyroid medication or develop side effects to them. Thyroidectomy can also be considered as primary therapy in refractory cases of amiodarone-induced hyperthyroidism. Thyroidectomy is not indicated for low RAIU hyperthyroidism.
- Patients should be rendered euthyroid with antithyroid drugs before surgery.
- Complications of surgery include hypothyroidism (28% to 43% after 10 yr), hypoparathyroidism, and vocal cord paralysis (1%).
- Most patients should be started on replacement doses of levothyroxine (1.7 mcg/kg/day) before discharge from hospital.
- Hyperthyroidism recurs after surgery in 10% to 15% of patients.

ADJUNCTIVE THERAPY: Propranolol alleviates the beta-adrenergic symptoms of hyperthyroidism; initial dose is 20 to 40 mg PO q6h; dosage is gradually increased until symptoms are controlled. Major contraindications to propranolol are congestive heart failure and bronchospasm. Diagnosis and treatment of thyrotoxic storm are also discussed in Section I.

CHRONIC Rx

- Patients undergoing treatment with antithyroid drugs should be seen every 1 to 3 mo until euthyroidism is achieved and every 3 to 4 mo while they remain on antithyroid therapy. After treatment is stopped, periodic monitoring of thyroid function tests with TSH is recommended every 3 mo for 1 yr, then every 6 mo for 1 yr, then annually.
- Orbital decompression surgery can be used to correct Graves orbitopathy (Fig. E2). The administration of the antioxidant selenium (100 mcg PO bid) has been recently reported as effective in improving quality of life, reducing ocular involvement, and slowing progression of the disease in patients with mild Graves orbitopathy. Its mechanism of action is believed to be an effect on the oxygen free radicals and cytokines that play a pathogenic role in Graves orbitopathy.

DISPOSITION

Successful treatment of hyperthyroidism requires lifelong monitoring for the onset of hypothyroidism or the recurrence of thyrotoxicosis.

REFERRAL

- Endocrinology referral is recommended at the time of initial diagnosis and during treatment.
- Surgical referral in selected patients (see "Surgical Therapy").
- Hospitalization of all patients with thyroid storm.

PEARLS & CONSIDERATIONS

COMMENTS

- Elderly hyperthyroid patients may have only subtle signs (weight loss, tachycardia, fine skin, brittle nails). This form is known as ***apathetic hyperthyroidism*** and manifests with lethargy rather than hyperkinetic activity. An enlarged thyroid gland may be absent. Coexisting medical disorders (most commonly cardiac disease) may also mask the symptoms. These patients often have unexplained congestive heart failure, worsening of angina, or new-onset atrial fibrillation resistant to treatment. See the topic "Graves Disease" for additional information on diagnosis and treatment.
- **Subclinical hyperthyroidism** is defined as a normal serum-free thyroxine and free triiodothyronine levels with a TSH level suppressed below the normal range and usually undetectable. Prevalence in the general population is 1% to 2%. These patients usually do not present with signs or symptoms of overt hyperthyroidism. Subclinical hyperthyroidism is associated with an increased risk of atrial fibrillation and heart failure in older adults. Treatment options include observation or a therapeutic trial of low-dose antithyroid agents for 6 mo to attempt to induce remission. The American Thyroid Association and the American Association of Clinical Endocrinologists recommend treatment of patients with TSH levels <0.1 mIU if they are older than 65 or have associated comorbidities (osteoporosis, heart failure).
- ***Thyrotoxic periodic paralysis (TPP)*** is a hyperthyroidism-related hypokalemia and muscle-weakening condition resulting from a sudden shift of potassium into cells. Many patients do not have other symptoms of hyperthyroidism. Typical presentation involves an Asian adult male with acute fatigue and muscle weakness initially presenting in the lower extremities. Physical examination reveals decreased deep tendon reflexes, hypertension, and tachycardia. ECG often reveals U waves, high QRS voltage, and first-degree atrioventricular block. Additional laboratory testing reveals normal acid-base state, hypokalemia with low urinary potassium excretion (spot urinary potassium concentration <20 mEq/L from potassium shift into cells), hypophosphatemia, hypophosphaturia, and hypercalciuria. Electromyography during attacks shows low-amplitude compound muscle action potential of the tested muscle. Therapy consists of cautious potassium supplementation (increased risk of rebound hyperkalemia). Use of nonselective beta-blockers (e.g., propranolol) to counteract hyperadrenergic activity, which may be causing TPP, may also be useful.

BASIC INFORMATION

DEFINITION

Hypertrophic osteoarthropathy (HOA) is a syndrome of abnormal proliferation of the skin and osseous tissues. Clubbing of the digits, periostitis of long bones, and synovial effusions can be seen. Clubbing may be asymptomatic, but patients with periostitis often have deep aching in long bones. HOA may be primary or secondary to other underlying disease processes such as cancer.

SYNONYMS

Primary hypertrophic osteoarthropathy
Pachydermoperiostosis
Idiopathic clubbing
Touraine-Solente-Golé syndrome
Secondary hypertrophic osteoarthropathy
HOA

M89.472	Other hypertrophic osteoarthropathy, left ankle and foot
M89.479	Other hypertrophic osteoarthropathy, unspecified ankle and foot
M89.48	Other hypertrophic osteoarthropathy, other site
M89.49	Other hypertrophic osteoarthropathy, multiple sites

EPIDEMIOLOGY & DEMOGRAPHICS

- Fig. 1 provides a classification of HOA.
- Primary HOA is a familial autosomal-dominant disease affecting the age group between 1 and 20 yr and is rare.
- There is a male:female ratio of 9:1.
- Secondary HOA is more common, typically occurs in adults 55 to 75 yr. 80% to 90% of secondary HOA is associated with non–small cell lung cancer, most frequently adenocarcinoma; other associated illnesses include:
  1. Pulmonary: Mesothelioma, bronchogenic carcinoma, lung abscesses, empyema, bronchiectasis, cystic fibrosis, pulmonary fibrosis, sarcoidosis, arteriovenous malformations
  2. Gastrointestinal: Carcinoma of esophagus or colon, biliary atresia, peptic ulcer disease, inflammatory bowel disease, hepatocellular carcinoma, liver cirrhosis, amebiasis, laxative abuse, achalasia
  3. Cardiac: Infective endocarditis, right-to-left cardiac shunts, aortic aneurysms, infected aortic bypass graft
  4. Hematologic: Thalassemia, myelofibrosis, Hodgkin lymphoma
  5. Endocrine: Thyroid acropachy, POEMS syndrome
  6. Connective tissue diseases
  7. Thymoma
  8. HIV infection
  9. Osteosarcoma
  10. Nasopharyngeal sarcoma

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Primary HOA typically presents with the insidious onset of clubbing of the hands and feet, described as "spade-like." Finger clubbing is diagnosed by measurement of the digital index (Fig. 2). Other signs and symptoms of HOA include:
  1. Joint pain and swelling
  2. Sensation of warmth or burning in the hands and feet
  3. Coarsening of facial features with grooves or depressions in the scalp, ptosis of the lids
  4. Thickening of the arms and legs
  5. Oily skin, diaphoresis, gynecomastia, and acne
  6. Thin and shiny appearance of the skin around the nail bed
  7. Nail convexity with nail "floating" sensation within the soft tissue is noticed on palpation of the base of the nail bed
  8. Elephant legs: Nonpitting soft tissue swelling with tenderness can be seen
- Secondary HOA patients may present with clinical symptoms before the underlying disorder can be detected. Signs and symptoms are similar to those seen in primary HOA, but there may be findings related to the underlying disease (e.g., lung carcinoma, infective endocarditis).
- Patients presenting with painful joints prior to developing clubbing can be misdiagnosed as having inflammatory arthritis.

ETIOLOGY

The pathogenesis of HOA (Fig. 3) is not fully understood; current knowledge suggests that HOA results from the activation of one or more growth factors and inflammatory mediators. Levels of vascular endothelial growth factor (VEGF) have been found to be elevated in both primary and secondary HOA. Platelet-derived growth factor secreted by megakaryocytes that normally are inactivated in the lungs and systemic circulation have been implicated in the etiology of HOA in the setting of pulmonary conditions and right-to-left shunts. Primary HOA likely has a genetic basis. Mutations in the HPGD gene that encodes for prostaglandin synthesis have been identified in some patients with this condition. The finding of hyperestrogenism in patients with HOA and simple clubbing led to a new hypothesis on the pathogenesis of HOA involving estrogens, prostaglandin E2, prostaglandin A2, and the inflammatory reflex.

DIAGNOSIS

Diagnosis is primarily clinical; radiographs and bone scans can help confirm the diagnosis.

DIFFERENTIAL DIAGNOSIS

Paget disease, reactive arthritis, psoriatic arthritis, syphilitic periostitis, osteoarthritis, rheumatoid arthritis, osteomyelitis, scleromyxedema, and acromegaly.

WORKUP

HOA warrants an investigation into finding a possible secondary association.

LABORATORY TESTS

- Routine laboratory studies such as blood count, electrolytes, and urine studies are typically normal in primary and secondary HOA.
- Erythrocyte sedimentation rate is usually elevated in secondary HOA.
- Liver function tests may be abnormal in patients with secondary HOA from gastrointestinal pathology.
- Alkaline phosphatase may be elevated as a result of periostitis of long bones.
- Analysis of the synovial fluid from joint effusions reveals a low white blood cell count with normal viscosity, color, and complement levels.

IMAGING STUDIES

- A chest radiograph should be obtained to rule out underlying lung cancer.
- Radiographs of the long bones show periosteal new bone formation (Fig. E4).
- Doppler ultrasound may be useful in identifying periostitis.

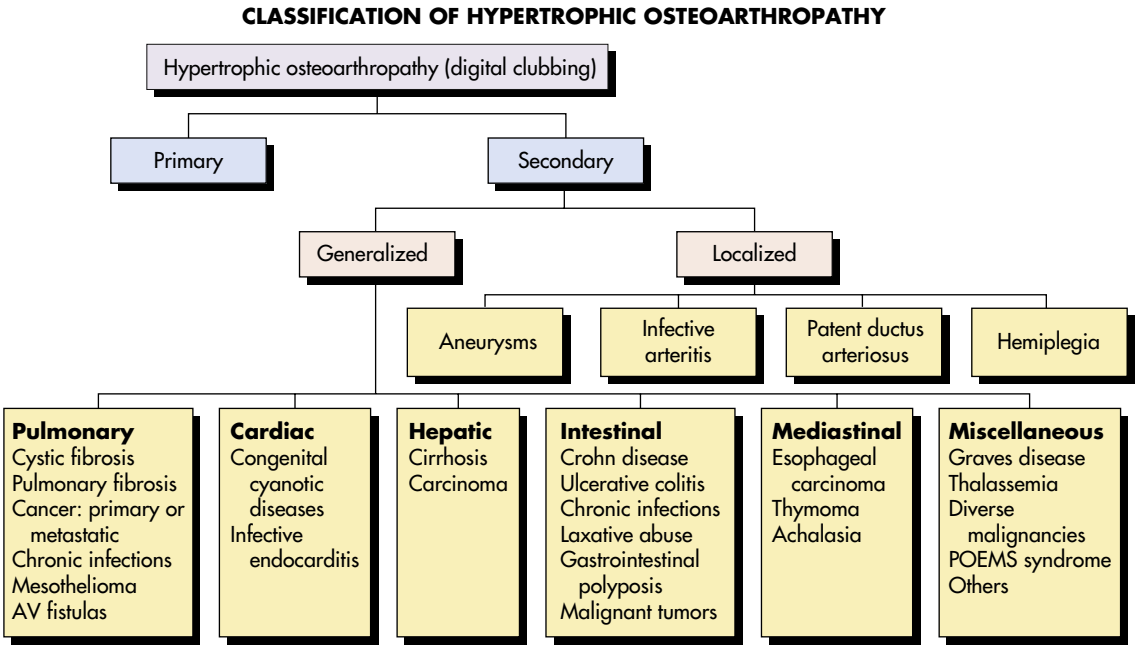

FIG. 1 Various forms of hypertrophic osteoarthropathy (HOA). *AV,* Arteriovenous; *POEMS,* polyneuropathy, organomegaly, endocrinopathy, monoclonal proteins, and skin changes. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

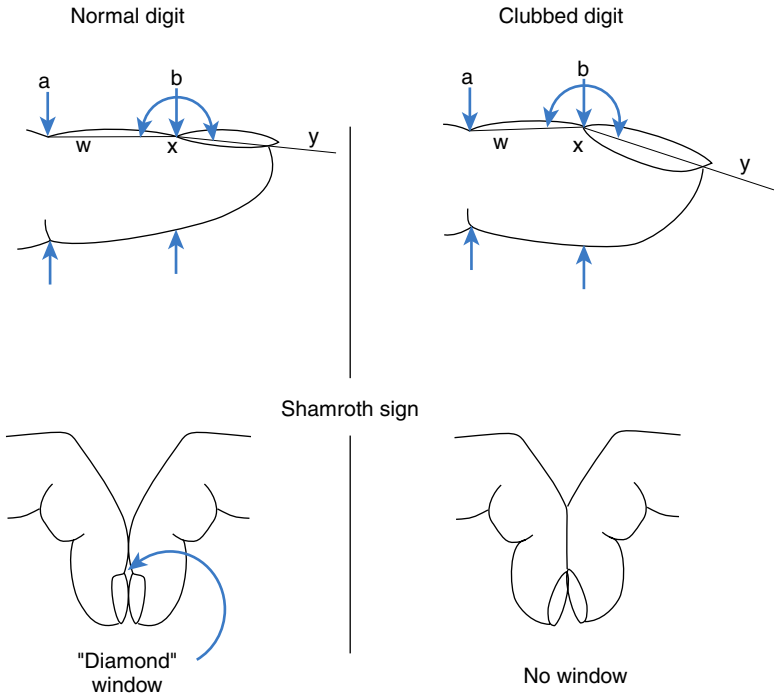

FIG. 2 Clubbing. The normal digit is on the left; the clubbed one, on the right. The distal interphalangeal joint is denoted by **A;** the junction of the nail and skin at the midline is denoted by **B.** The interphalangeal depth ratio is the ratio of the digit's depth measured at **B** divided by that at **A.** The hyponychial angle is the angle *wxy.* In the figure, the depth ratio is 0.9 for the normal digit and 1.2 for the clubbed digit (a ratio >1 indicates clubbing), and the hyponychial angle is 185 degrees for the normal digit and 200 degrees for the clubbed digit (a hyponychial angle >190 degrees indicates clubbing). The Shamroth sign refers to the absence of the diamond-shaped window that normally appears when the terminal phalanges of similar digits are opposed to each other. (From McGee S: *Evidence-based physical diagnosis,* ed 4, Philadelphia, 2018, Elsevier.)

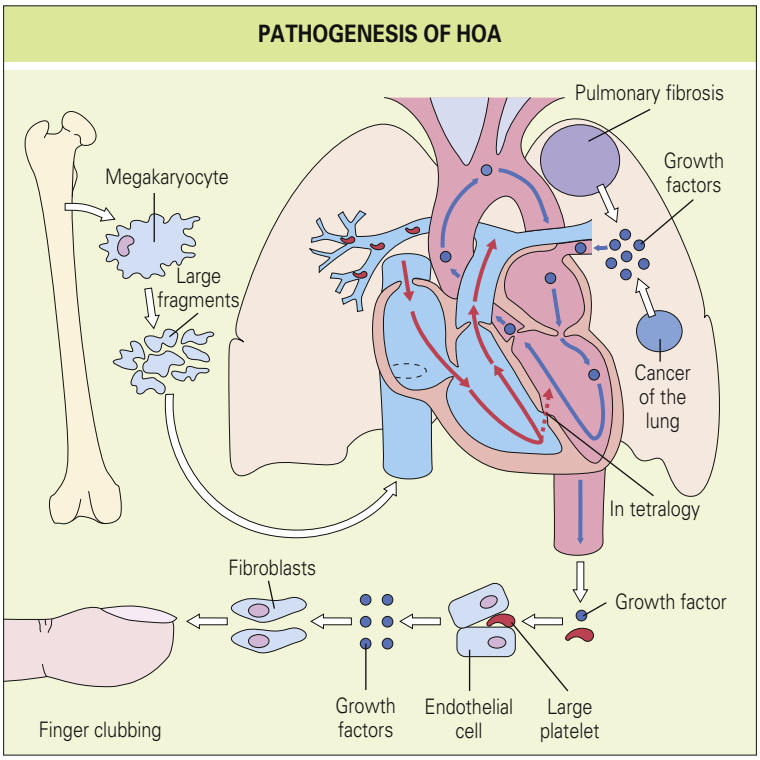

FIG. 3 Theoretic explanation for the development of hypertrophic osteoarthropathy (HOA). Megakaryocytes emerge from the bone marrow and, in normal circumstances, are fragmented in the lung microvasculature. In individuals with cyanotic heart disease (in this case, tetralogy of Fallot), the large fragments would not enter the pulmonary circulation; instead, they would directly enter the systemic circulation, reach its most distal sites, release growth factors, activate endothelial cells, and thus induce finger clubbing. In individuals with lung cancer, a growth factor derived from abnormal tissue would enter the systemic circulation and induce clubbing. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

- Bone scan with technetium-99m reveals cortical uptake.
- Single photon emission computed tomography (SPECT)/CT can increase specificity by excluding bony metastasis.
- Angiography findings may demonstrate hypervascularization of the finger pads.

Rx TREATMENT

ACUTE GENERAL Rx

- Treatment of primary HOA is symptomatic. Nonsteroidal antiinflammatory medications, corticosteroids, tamoxifen citrate, or retinoids can be used.
- Colchicine can be helpful for the pain due to subperiosteal new bone formation.
- Reconstructive surgery is indicated for correction of gross disfigurement.
- Case reports of improvement in symptoms of primary HOA with infliximab and arthroscopic synovectomy.
- Treatment of secondary HOA is to treat the underlying disease. Correction of heart malformation or removal of an underlying tumor can be followed by regression of HOA. NSAIDs for symptomatic relief, joint aspiration/injection.

CHRONIC Rx

In patients with secondary HOA refractory to NSAIDs and aspirin, octreotide (100 mcg subcutaneously twice daily) and bisphosphonates, including pamidronate (1 mg/kg intravenously to a maximum of 60 mg) and zoledronic acid, which inhibit VEGF expression, have been found to be highly effective. Vagotomy has been tried with some success. Definitive treatment remains to treat the underlying disease.

REFERRAL

Referral should be made to rheumatology when the diagnosis of HOA is suspected and the cause remains unclear.

PEARLS & CONSIDERATIONS

- Symptoms of joint pain and swelling in patients with primary HOA often improve with time.
- Prognosis and disease course in patients with secondary HOA will depend on the underlying cause.
- The insidious development of clubbing suggests an infectious process, whereas the rapid progression of clubbing may suggest underlying malignancy.

COMMENTS

Infections and intrathoracic malignancies are the most common causes of secondary HOA. HOA secondary to infection of an arterial graft has been reported.

BASIC INFORMATION

DEFINITION

Hyperuricemia may be defined as serum uric acid >7.0 mg/dl in males or >6.0 mg/dl in females. Some persons, who are not hyperuricemic by this definition, will have levels of uric acid that exceed the limit of solubility of uric acid in tissue. Data from the Framingham study indicate that hyperuricemia increased from 4.8% of the population in the early 1970s to 9.3% in the mid-1980s. Age is an important risk factor in the increasing incidence of hyperuricemia and gout. Women become hyperuricemic at an older age than men due to the uricosuric effect of estrogen. Most people with hyperuricemia are asymptomatic and will remain so; however, 20% of those with serum uric acid >9 mg/dl will develop gout in 5 yrs. Hyperuricemia is strongly associated with gout, obesity, diabetes, hypertension, and cardiovascular disease but has not been proven to cause any of these conditions.

ASYMPTOMATIC HYPERURICEMIA

Definition: Laboratory evidence of elevated serum uric acid without clinical disease known to be caused by hyperuricemia

ICD-10CM CODE

E79.0 Hyperuricemia without signs of inflammatory arthritis and tophaceous disease

ETIOLOGY

Factors associated with urate variation are summarized in Table E1. Overproduction of uric acid accounts for a minority of cases of hyperuricemia. Most cases are due to decreased renal clearance of uric acid and high dietary purine consumption. Fig. E1 describes factors affecting urate balance. Table E2 describes classification of hyperuricemia and gout.

DIAGNOSIS

EVALUATION

The finding of hyperuricemia should prompt a thorough evaluation of potential causes and related diseases. Fig. E2 describes the evaluation of patients with hyperuricemia. If there is no clinical evidence of gout, nephrolithiasis, or acute kidney injury, the patient may be said to have asymptomatic hyperuricemia. Potential causes of elevated uric acid include malignancy, renal insufficiency, toxins, lead toxicity, and dietary indiscretion. If a careful history and physical exam do not reveal an evident cause of persistent hyperuricemia, a 24-hour urine collection for uric acid and creatinine may be considered. Patients with urinary excretion of uric acid >800 mg/24 hours are likely to be overproducers of uric acid and should be investigated more thoroughly for the underlying cause of their hyperuricemia.

LABORATORY TESTS

- CBC with differential
- CMP (blood urea nitrogen [BUN]/creatinine)
- Urinalysis
- Lipid profile
- Consider 24-hour urine collection for uric acid

TREATMENT

No specific therapy is indicated for most patients with asymptomatic hyperuricemia. Lifestyle and dietary modification are often advisable.

NONPHARMACOLOGIC THERAPY

- Weight loss, regular exercise
- Reduce alcohol intake, especially beer

TABLE E1 Factors associated with urate variation

Genetic factors	Dietary influences	Clinical associations
Male sex Common variants associated with hyperuricemia (replicated) • *SLC2A9* • *ABCG2* • *PDZK1* • *GCKR* • *RREB1* • *SLC17A3* ■ *SLC16A9* • *SLC22A11* • *SLC22A12* • *INHBC* Rare monogenic causes • HPRT deficiencies: Complete (Lesch-Nyhan syndrome), partial (Kelley-Seegmiller syndrome) • PRPP synthetase overactivity • Glucose-6-phosphatase deficiency • Fructose-1-P aldolase deficiency • Myogenic glycogenoses (types III, V, VII) • Uromodulin-associated kidney disease: FJHN, MCKD types 1 and 2	Associated with increased urate • High purine foods (e.g., red meat, liver, offal, shellfish) • Fructose- and sugar-sweetened drinks • Alcohol (beer and spirits) Associated with lower urate • Low-fat dairy products • Cherries • Vitamin C • Coffee	Older age Postmenopause in women Medical comorbidities • Hemolytic disorders • Hemopoietic malignancies; tumor lysis • Lactic or ketoacidosis; hypoxemic states • Lead nephropathy, chronic low-level exposure • Preeclampsia • Renal impairment • Psoriasis • Vasopressin-resistant diabetes insipidus • Bartter and Gitelman syndromes • Down syndrome • Hypertriglyceridemia • Hypertension • Obesity • Cardiovascular disease Medications associated with hyperuricemia • Aspirin (low dose) • Chemotherapeutic cytotoxics • Diuretics • Pyrazinamide • Ethanol • Levodopa • Nicotinic acid • Cyclosporine and tacrolimus Medications associated with reduced serum urate Losartan • Fenofibrate • Leflunomide • Calcium channel blockers • Atorvastatin • Sevelamer

FJHN, Familial juvenile hyperuricemic nephropathy; *HPRT,* hypoxanthine-guanine phosphoribosyltransferase; *MCKD,* medullary cystic kidney disease; *PRPP,* 5-phosphoribosyl 1-pyrophosphate.
From Hochberg MC: Rheumatology, ed 7, Philadelphia, 2019, Elsevier.

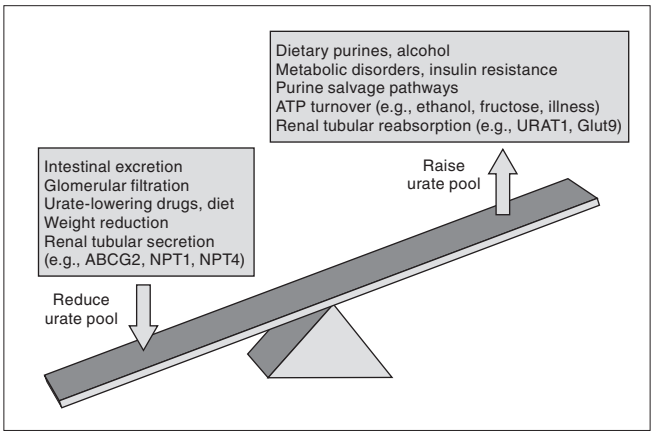

FIG. E1 Factors affecting urate balance. The systemic urate pool and the likelihood of gout are determined by the dynamic balance among dietary purines, endogenous synthesis and recycling, and disposal by the kidney and gut. *ATP,* Adenosine triphosphate. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

TABLE E2 Classification of Hyperuricemia and Gout

Impaired Uric Acid Excretion
Primary gout with decreased uric acid clearance
Secondary gout
Clinical conditions
Reduced glomerular filtration rate
Hypertension
Obesity
Systemic acidosis
Familial juvenile hyperuricemic nephropathy
Medullary cystic kidney disease
Lead nephropathy
Drugs
Diuretics
Ethanol
Low-dose salicylates (0.3-3.0 g/day)
Cyclosporine
Tacrolimus
Levodopa
Excessive urate production
Primary metabolic disorders
HPRT deficiency
PRPP synthetase overactivity
Glucose-6-phosphatase deficiency
Fructose-1-phosphate aldolase deficiency
Secondary causes
Clinical conditions
Myelo- and lymphoproliferative disorders
Obesity
Psoriasis
Glycogenoses III, V, VII
Drugs and dietary components
Nicotinic acid
Pancreatic extract
Cytotoxic drugs
Red meat, organ meat, shellfish
Alcoholic beverages (especially beer)
Fructose

HPRT, Hypoxanthine-guanine phosphoribosyltransferase; *PRPP,* phosphoribosyl pyrophosphate.
From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, WB Saunders.

- Reduce consumption of foods known to be high in purines such as red meat, organ meat, and high-fructose soft drinks

PEARLS & CONSIDERATIONS

- Research suggests there may be a causal relationship between hyperuricemia and early hypertension.
- If drug can be used to decrease hyperuricemia for an alternative condition, should consider this (hypertension: Use losartan or CCB, avoid diuretic if possible)
- Very high levels of serum uric acid may warrant treatment even if asymptomatic.
- Patients with hyperuricemia and a family history of gout should be followed closely for the development of gouty arthritis.
- Hyperuricemia in patients with gout should almost always be treated with urate-lowering medication (see "Gout"). The presence of gouty tophi or arthritis due to gout is generally an absolute indication for urate-lowering therapy.

There is evidence from several sources suggesting that treatment of hyperuricemia slows the progression of chronic kidney disease (CKD) in patients without gout. However, one large randomized controlled study of febuxostat therapy in stage 3 CKD conducted in Japan was unable to replicate this finding. Current recommendations do not support the use of urate-lowering therapy in CKD unless there is concomitant gout, but the issue needs further study.

Recent studies have suggested that allopurinol use is associated with a reduced risk of myocardial infarction and reduction in all-cause mortality. These preliminary studies have sparked renewed research interest.

Hypoactive Sexual Desire Disorder (HSDD)

BASIC INFORMATION

DEFINITION

- Persistently or recurrently diminished or absent sexual/erotic thoughts or fantasies and desire for sexual activity.
- The judgment of deficiency is made by the clinician taking into account factors related to age, social context, and general contexts of the individual's life.
- Symptoms must have been present for a minimum of 6 mo, the majority of the time, and be distressing to the individual.
- The lack of desire must not be better explained by a nonsexual mental disorder or by severe relationship distress or other significant stressor.
- Must also not be better attributable to substance/medication or another medical condition.

SYNONYMS

Subsumed in female sexual interest/arousal disorder
Hypoactive sexual desire disorder, situational
Psychosexual desire disorder, situational hypoactive
Psychosexual dysfunction associated with inhibited libido
Psychosexual dysfunction with inhibited libido
Situational hypoactive sexual desire disorder
HSDD

ICD-10CM CODES
F52.0 Hypoactive sexual desire disorder
F52.22 Female sexual arousal disorder
DSM-5 CODES
302.71
302.72

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: Prevalence of low sexual desire increases with age. Middle-aged women (45 to 65 yr old) and men over 60 appear at greatest risk of experiencing qualifying distress.
PREVALENCE:

- Among males, rates of HSDD vary depending on country of origin and means of assessment. Generally, 6% of men 18 to 24 and 41% of men 66 to 74 report problems with sexual desire. Persistent lack of sexual interest that lasts longer than 6 mo is seen in approximately 1.8% of men 16 to 44.
- For women, rates of HSDD are more uncertain, especially given the new inclusion of HSDD into female sexual interest/arousal disorder. Prior studies with less stringent criteria suggest approximately 36% of women endorse low sexual desire, but roughly only 8% report experiencing clinical levels of related distress. These rates also vary by country of origin and method of assessment (Fig. E1).

PREDOMINANT SEX & AGE: HSDD appears to be more prevalent in women; however, men are more likely to be underdiagnosed or misdiagnosed with another sexual dysfunction.
GENETICS: There appears to be a strong influence of genetics in the vulnerability of women to sexual dysfunction. Specifically, women with the ll genotype for the SCL6A4 promoter region (5HTTLPR) appear to be eight times more likely to have selective serotonin reuptake inhibitor (SSRI) associated sexual dysfunction if they are also taking oral contraceptives. Men with the ll genotype have also been found to be at greater risk of sexual dysfunction. Similarly, dopamine (D4) receptor polymorphisms influence all phases of the sexual response cycle.
RISK FACTORS: Temperamental and environmental risk factors for HSDD include mood and anxiety symptoms, negative cognitions about sexuality or relationship, alcohol use, early childhood trauma, interpersonal problems, and lack of adequate sex education. Physiologic risk factors include age, medical conditions such as diabetes mellitus, thyroid dysfunction, hyperprolactinemia, coronary disease, renal failure, and androgen deficiency, as well as other neuroendocrine changes.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- HSDD can be lifelong or acquired as well as generalized or situational.
- Men appear more likely to present with the acquired, situational subtype.
- For women, lack of pleasure is a common presenting clinical complaint.
- Consideration of initiation of sexual activity and receptivity to sexual activity initiated by the partner should be assessed. Men are often more likely to initiate sexual encounters, and noninitiation may be a signifier of a possible problem, but any shift in pattern of initiation should be investigated further.
- Other sexual activities such as masturbation or partnered sexual activity may still occur even in the context of low sexual desire.
- The interpersonal context of HSDD should be taken into account, as often a desire discrepancy between partners leads to discussions of possible HSDD, but this is not sufficient for diagnosis.
- Symptoms should be present for approximately 6 mo, but clinical judgment can be used if symptoms are of lesser duration.

ETIOLOGY

Best evidence suggests a multifactorial etiology, including factors along the biopsychosocial continuum, including genetic vulnerability, interpersonal distress, cultural factors, mental health, medical conditions, and medical treatments.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

If low sexual desire can be attributed largely to one of these factors, HSDD should not be diagnosed, and the underlying factor should be addressed.

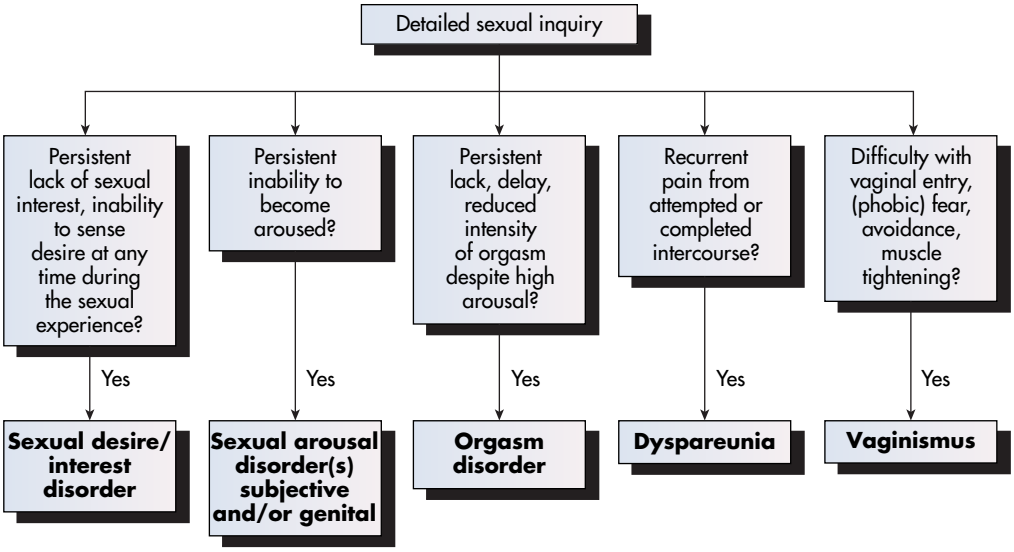

FIG. E1 Currently recommended definitions for women's sexual dysfunction. Comorbidity is usual, especially sexual desire/interest disorder with one of the sexual arousal disorders. (From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, WB Saunders.)

- Nonsexual mental disorder: Depression, anxiety, posttraumatic stress disorder, and schizophrenia
- Substance/medication use: Drugs of abuse (e.g., alcohol), anticonvulsants (e.g., carbamazepine), cardiovascular and antihypertensive agents (e.g., clonidine), hormonal medications (e.g., oral contraceptives), and psychotropic medications (e.g., SSRIs)
- Another medical condition: Endocrine disorders (e.g., diabetes mellitus), coronary artery disease, cancer, central nervous system disease, hypertension, and arthritis
- Interpersonal factors: Relationship discord, partner sexual problems, dissatisfaction with partner or relationship, communication deficits, and intimate partner violence
- Other sexual dysfunctions: Erectile disorder, female orgasmic disorder, and genitopelvic pain/penetration disorder

WORKUP

- Clinical interview should include a sexual history, medical history, and psychosocial history. The sexual history should include questions about prior sexual issues, sexual behavior and practices, and patient's treatment goals.
- A physical examination may be warranted for some female patients to identify possible contributing factors to low desire such as vulvovaginal atrophy, genital sensory changes, and pelvic floor prolapse.
- Symptoms of depression and anxiety should be assessed. This can be done with brief screeners such as the Patient Health Questionnaire-9 (PHQ-9) and Generalized Anxiety Disorder-7 (GAD-7).
- Adequate endocrine functioning can be assessed through a combination of history taking (e.g., menstrual patterns) and laboratory tests when warranted by history.
- Self-rating scales and standardized symptom-specific checklist may be helpful in diagnosis and determining treatment. Example screeners include the Brief Sexual Symptom Checklist (BSSC), the Decreased Sexual Desire Screener (DSDS), and Female Sexual Function Index (FSFI).

LABORATORY TESTS

- Laboratory tests should be undertaken if indicated by history or physical exam.
- Common tests include:
  1. Thyroid function, serum total testosterone, prolactin, follicle-stimulating hormone (FSH), and luteinizing hormone (LH)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Multimodal interventions are often needed to address the complex etiology of HSDD.
- Basic sex education can be a valuable in-office intervention that can alleviate distress that arises from unrealistic norms or misunderstandings related to basic reproductive anatomy and physiology.
- Simple suggestions related to reducing stress, increasing communication with partner, and leading a healthy lifestyle can help to improve sexual function for some.
- Patients should be referred for psychological intervention when medical rule-outs have been completed. Therapist should have experience with treating sexual problems.
- The number of controlled trials studying the efficacy of psychological treatment for HSDD is limited; however, available evidence suggests significant improvements with the use of cognitive behavioral therapy, mindfulness-based approaches, traditional sex therapy, or a combination.
- There is support for both individual- and couple-based treatments.

ACUTE GENERAL Rx

- Currently, only one FDA-approved treatment exists for premenopausal women with HSDD: Flibanserin (Addyi). Addyi is a multifunctional serotonin agonist/antagonist that passes through the blood-brain barrier and selectively affects the prefrontal cortex. Addyi has been shown to increase the number of satisfying sexual events per mo.
- Addyi is contraindicated for use with moderate and strong CYP3A4 inhibitors, with alcohol, and in patients with hepatic impairments. Side effects include dizziness, somnolence, fatigue, and nausea.
- The FDA has required a Risk Evaluation and Mitigation Strategy (REMS) for Addyi, which requires prescribers and pharmacies to be certified in the REMS program to prescribe and dispense. More information is available at: https://addyirems.com/AddyiUI/rems/home.action.
- Bupropion hydrochloride is a mild dopamine and norepinephrine reuptake inhibitor and nicotinic acetylcholine receptor antagonist that is used as an antidepressant and smoking cessation aid. There is some empirical evidence for off-label use suggesting that bupropion significantly increases sexual desire in nondepressed women. It has also been shown to be effective in reversing SSRI-induced sexual dysfunction.
- Buspirone is a serotonin 1A partial agonist and is used off-label for treatment of HSDD. It has been shown to reduce low-desire side effects of SSRIs when coadministered.
- Testosterone is widely prescribed off-label for postmenopausal women, with substantial evidence suggesting testosterone therapy improves sexual well-being among postmenopausal women. There is limited evidence for similar effects among premenopausal women.
- Testosterone is a well-established treatment for men with HSDD secondary to low testosterone.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Recent studies have shown good preliminary efficacy of treating both sexual arousal and desire disorders with mindfulness, yoga, and meditation as a complement to psychotherapy.

DISPOSITION

- HSDD is a common sexual dysfunction that affects both men and women across the life span. With appropriate identification and treatment, many patients will experience improvement in sexual desire; however, finding appropriate referrals and support for patients may be challenging.
- Specific types of HSDD can resolve in time untreated if a patient's contextual factors change (e.g., new partner), but for others HSDD will persist or worsen without treatment.
- Patients may be at higher risk for relationship discord and other psychiatric disorders such as depression and anxiety.

REFERRAL

- Most patients presenting with HSDD would benefit from referral to a therapist skilled in treating sexual problems.
- Patients with unresolved physical or sexual trauma should be promptly referred to a specialist.
- Establishing a referral network of specialists in sexual medicine and therapy is important.

PEARLS & CONSIDERATIONS

- Biologic and psychological factors often comingle and contribute to the individual picture of HSDD.
- Linguistic and cultural variations can heavily impact the presentation of HSDD and the associated distress as well as treatment.
- New FDA-approved medication Addyi remains controversial among sexual medicine specialists.
- Discussions of potential sexual side effects of medications and of general sexual health with all patients will allow for more open conversations when problems do arise.

BASIC INFORMATION

DEFINITION

Hypoaldosteronism is defined as an aldosterone deficiency or impaired aldosterone function.

ICD-10CM CODES

E27.40	Unspecified adrenocortical insufficiency
E27.3	Drug-induced adrenocortical insufficiency
E27.9	Disorder of adrenal gland, unspecified
E27.1	Primary adrenocortical insufficiency
E27.40	Unspecified adrenocortical insufficiency
E27.49	Other adrenocortical insufficiency

EPIDEMIOLOGY & DEMOGRAPHICS

Selective hypoaldosteronism accounts for as many as 10% of cases of unexplained hyperkalemia.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Physical examination may be entirely within normal limits.
- Hypertension may be present in some patients.
- Profound muscle weakness and cardiac arrhythmias may be present.

ETIOLOGY

- Hyporeninemic hypoaldosteronism (renin-angiotensin dependent): Decreased aldosterone production as a result of decreased renin production; the typical patient has renal disease attributable to various factors (e.g., diabetes mellitus, interstitial nephritis, multiple myeloma, HIV infection, urinary tract obstruction, aging) and medications (NSAIDs, COX-2 inhibitors, ACEI/ARBs).
- Hyperreninemic hypoaldosteronism (renin-angiotensin independent): Renin production by the kidneys is intact; the defect is in aldosterone biosynthesis or in the action of angiotensin II. Common causes of this form of hypoaldosteronism are medications (ketoconazole, heparin), lead poisoning, aldosterone enzyme defects, and severe illness.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Pseudohypoaldosteronism: Renal unresponsiveness to aldosterone. In this condition both renin and aldosterone levels are elevated. Pseudohypoaldosteronism can be caused by medications (spironolactone), chronic interstitial nephritis, systemic disorders (systemic lupus erythematosus, amyloidosis), or primary mineralocorticoid resistance.

WORKUP

Measurement of plasma renin activity after 4 hr of upright posture can differentiate hyporeninemic from hyperreninemic causes. Renin levels in the normal or low range identify cases that are renin-angiotensin dependent, whereas high renin levels identify cases that are renin-angiotensin independent. The diagnosis and etiology of hypoaldosteronism can be confirmed with the renin-aldosterone stimulation test:

- Hyporeninemic hypoaldosteronism: Low stimulated renin and aldosterone levels
- End-organ refractoriness to aldosterone action: High stimulated renin and aldosterone levels
- Adrenal gland abnormality: High stimulated renin and low aldosterone levels

LABORATORY TESTS

- Increased potassium, normal or decreased sodium
- Hyperchloremic metabolic acidosis (caused by the absence of hydrogen-secreting action of aldosterone)
- Increased BUN and creatinine (secondary to renal disease)
- Hyperglycemia (diabetes mellitus is common in these patients)

TREATMENT

NONPHARMACOLOGIC THERAPY

- Low-potassium diet with liberal sodium intake (at least 4g of sodium chloride per day)
- Avoidance of ACE inhibitors and potassium-sparing diuretics

ACUTE GENERAL Rx

- Judicious use of fludrocortisone (0.05 to 0.1 mg PO every morning) in patients with aldosterone deficiency associated with deficiency of adrenal glucocorticoid hormones
- Furosemide 20 to 40 mg qd to correct hyperkalemia of hyporeninemic hypoaldosteronism

DISPOSITION

Prognosis varies with the etiology of hypoaldosteronism and presence of associated disorders.

REFERRAL

Endocrinology referral for renin-aldosterone stimulation test

PEARLS & CONSIDERATIONS

COMMENTS

Treatment of pseudohypoaldosteronism is the same as for hypoaldosteronism; however, effect is limited because of impaired renal sensitivity.

RELATED CONTENT

Hyperkalemia (Related Key Topic)

AUTHOR: **Fred F. Ferri, MD**

Hypochondriasis (Illness Anxiety Disorder) PTG

BASIC INFORMATION

DEFINITION

Illness anxiety disorder is a newly defined diagnosis in the *Diagnostic and Statistical Manual of Mental Disorders,* ed 5 (DSM-5). In the DSM-5, hypochondriasis and related conditions were replaced by two new concepts: Illness anxiety disorder (somatic symptoms absent or minimal; concern focused on the idea of illness) and somatic symptom disorder (somatic symptoms present, with significant related distress and impairment)—both diagnostic subtypes of the DSM-5 Somatic Symptom and Related Disorders category (Somatoform disorders in DSM-IV).

Illness anxiety disorder, referred to more generally as *health anxiety*, is marked by the preoccupation with the fear of having, or the idea that one has, a serious undiagnosed disease, despite a lack of significant corresponding somatic symptoms or medical evidence. Whether or not a medical diagnosis is present, the severity of health-related anxiety is clearly disproportionate to the individual's health status. Most medical literature explores the previously defined disorder hypochondriasis; it is unknown exactly how that evidence applies to illness anxiety disorder.

SYNONYMS

Hypochondriasis
Illness anxiety disorder
Somatoform disorder (DSM-IV)
Health anxiety

ICD-10CM CODE
F45.21 Hypochondriasis
DSM-5 CODE
300.7 Illness anxiety disorder

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: 1% to 5% (based on estimates of DSM-III and DSM-IV disorder hypochondriasis) but may be higher (3% to 10%) in primary care outpatient settings
PREDOMINANT SEX: Equal frequency in men and women
PREDOMINANT AGE: Onset at any age, but most commonly between ages 20 and 30 yr

GENETICS/RISK

No known genetic component. May be more common in less-educated individuals. A comorbid mental disorder (e.g., generalized anxiety, obsessive-compulsive disorder, or depression) may affect over two thirds of individuals with illness anxiety disorder; personality disorders and other somatic symptom disorders may also be more common.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Somatic symptoms or signs are not present or are only mild; the focus of anxiety is the suspected medical diagnosis itself (i.e., concern for illness rather than symptoms per se).
- Mild somatic symptoms, if present, often include nonpathologic physical signs or sensations (e.g., belching, orthostatic light-headedness).
- High health-related anxiety persists despite reassuring clinical evaluation (without the intensity of a delusion).
- Illness anxiety symptoms often correlate with psychosocial stressors.
- Illness preoccupation lasts at least 6 mo (the specific illness feared may vary).
- Disruption in health-related quality of life and/or social, occupational, or other important areas of functioning.
- Two presentation types: Care-seeking (medical attention frequently sought) and care-avoidant (maladaptive avoidance of health care).
- No specific physical examination findings.

ETIOLOGY

Unknown neurobiologic etiology. Serious childhood illness or trauma may be associated with illness anxiety disorder in adulthood.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Underlying medical condition
- Delusional disorder (somatic type—fixed delusion of illness despite evidence to the contrary)
- Adjustment disorder (health-related anxiety in response to identifiable or documented medical illness)
- Somatic symptom disorder (excessive distress related to somatic symptom[s]) (medically unexplained symptoms)
- Body dysmorphic disorder (restricted to a circumscribed concern about appearance)
- Generalized anxiety disorder with health concerns as one worry among others
- Major depressive disorder with health concerns occurring only during depressive episodes
- Psychosis, as may occur with depression and schizophrenia
- Factitious disorder (formerly Munchausen syndrome)
- Malingering

WORKUP

- History, physical examination, age-appropriate screenings, and laboratory and imaging tests, as appropriate, to exclude underlying medical condition
- Symptom measures (e.g., Health Anxiety Inventory) may be used for detection and monitoring of severity over time
- Evaluation for other psychiatric disorders associated with illness anxiety, such as depression and generalized anxiety

TREATMENT

NONPHARMACOLOGIC THERAPY

- Psychotherapy, specifically cognitive behavioral therapy (CBT), is the mainstay of treatment, with techniques to alter or restructure maladaptive thinking and behavior and to improve coping with health anxiety. Individual or group CBT, acceptance and commitment therapy (ACT), behavioral stress management, and mindfulness-based approaches, including Internet-based treatments, have demonstrated success
- Regularly scheduled brief medical appointments not contingent on symptoms
- Emphasis on care coordination
- Avoidance of the suggestion that symptoms are "all in your head"
- Education about illness anxiety diagnosis and framing of psychosomatic experience (on a spectrum of normal to excessive)
- Emphasis on optimization of function (rather than cure) as the goal of treatment
- Avoidance of repeated or nonmedically indicated diagnostic testing, referrals, or treatments
- Limit on reading medical texts or websites
- Benign interventions to reduce stress and build resilience (e.g., exercise, massage, meditation, social support, sleep hygiene, etc.)

CHRONIC Rx

- Antidepressants may be helpful even in individuals without features of depression: Placebo-controlled trials of fluoxetine and paroxetine suggest benefit. Norepinephrine-serotonin reuptake inhibitors (NSRIs) such as duloxetine have documented efficacy in the treatment of pain related to depression and associated with medical conditions (fibromyalgia, diffuse musculoskeletal pain [osteoarthritis]) often comorbid with psychiatric illness.
- Treatment of comorbid psychiatric conditions, if present.

DISPOSITION

Waxing and waning course over decades; recovery rates between 30% and 85%. Positive prognostic factors include shorter duration of illness anxiety and lack of comorbid psychiatric disorder.

REFERRAL

Referral for CBT is the mainstay of treatment; referral to a psychiatrist may be needed in the case of comorbid psychiatric condition.

PEARLS & CONSIDERATIONS

- The primary goal in treating illness anxiety is to improve patients' ability to cope with health fears.
- Psychotherapy and pharmacotherapy may be helpful treatment modalities for individuals open to treatment not directed at the perceived illness.
- In the updated DSM-5, hypochondriasis and related somatoform disorders were replaced by two new concepts: Somatic symptom disorder (somatic symptoms present, with significant related distress) and illness anxiety disorder (somatic symptoms absent or minimal; concern focused on the idea of illness).

Hypocomplementemic Urticarial Vasculitis

BASIC INFORMATION

DEFINITION

- Hypocomplementemic urticarial vasculitis (HUV) is the term used to describe patients with urticarial vasculitis and hypocomplementemia who do not meet diagnostic criteria for hypocomplementemic urticarial vasculitis syndrome.
- In general, patients with HUV have cutaneous disease and few or no systemic manifestations.

SYNONYMS

Urticarial vasculitis
Hypocomplementemic urticarial vasculitis syndrome
HUV

ICD-10CM CODE
M31.8 Hypocomplementemic vasculitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Urticarial vasculitis (UV) is a rare diagnosis.
- The incidence and prevalence of the disorder are uncertain.

PEAK INCIDENCE: The peak reported incidence is in the fourth decade of life.

PREVALENCE: The prevalence of UV in patients with chronic urticaria varies from 5% to 20%.

PREDOMINANT AGE AND SEX:

- Women comprise 60% to 80% of reported patients.
- UV has also been described in children; the youngest reported case occurred in a patient 1 yr of age.

GENETICS: A study including two families with autosomal-recessive HUVS found that mutations in *DNASE1L3* were associated with a familial form of HUVS and HUVS associated with SLE.

RISK FACTORS:

- The association with some disorders in which the antigen-antibody complexes are well defined (e.g., hepatitis B, hepatitis C), and the observation that removal of immune complexes by plasmapheresis is temporally associated with the resolution of the urticarial lesions.
- Medications and viruses (particularly hepatitis B and C) have been implicated as the target antigen in some cases.
- There have also been reports demonstrating the development of UV in association with infliximab, glatiramer acetate, and the injection of hyaluronic acid.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- **Dermatologic:** The urticarial lesions (or wheals) of urticarial vasculitis (UV) can be found anywhere on the body. Urticarial lesions are typically more pruritic than painful and can be associated with angioedema, purpura, and livedo reticularis.
- **Musculoskeletal:** Arthralgias and arthritis are the most common systemic manifestation of UV. Joint pain is usually migratory and transient, frequently affecting the hands, elbows, feet, ankles, and knees.
- **Renal:** Renal disease is characterized by proteinuria and hematuria. The renal disease of UV includes proliferative glomerulonephritis, focal necrotizing vasculitis, crescentic glomerulonephritis, membranoproliferative glomerulonephritis, and tubulointerstitial nephritis. The renal involvement of UV tends to be more severe in children.
- **Pulmonary:** Pulmonary involvement is a leading cause of morbidity and mortality in UV and may include cough, dyspnea, hemoptysis, chronic obstructive pulmonary disease (COPD), asthma, pleuritis, and pleural effusions. The most common pulmonary manifestations are COPD and asthma.
- Smoking accelerates pulmonary parenchymal destruction by helping to recruit neutrophils. Thus, patients with UV should not smoke and should avoid secondhand smoke.
- **Gastrointestinal:** GI symptoms include substernal pain, abdominal pain, nausea, vomiting, and diarrhea. Hepatomegaly and splenomegaly have been reported.
- **Ophthalmologic:** Ophthalmologic symptoms include episcleritis, uveitis, and conjunctivitis. A rare case of serpiginous choroidopathy with subsequent blindness was reported; optic atrophy has been reported also.
- **Cardiovascular:** Symptoms include pericarditis, tamponade, valvular disease, and pericardial effusion.
- **Neurologic:** Central nervous system (CNS) involvement includes pseudotumor cerebri (the most common CNS manifestation), aseptic meningitis, cranial nerve palsies, peripheral neuropathy, and transverse myelitis.

ETIOLOGY

- HUV results from the formation of immune complexes in the blood that then deposit in vessel walls.
- In some patients with UV (particularly those with hypocomplementemic urticarial vasculitis), a collagen-like region on C1q has been implicated as the antigenic target.
- The autoantibody is referred to as a C1q precipitin.
- Once antigen-antibody complexes have formed, they can activate the classical complement pathway. This generates C3a and C5a, which cause mast cell degranulation resulting in urticarial eruptions. C3a and C5a also cause increased vessel permeability and chemotaxis of neutrophils.
- Infiltrating neutrophils release proteolytic enzymes, causing further tissue destruction and edema.
- IL-1 may play a role in the pathogenesis of UV.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Common urticarial
- Erythema multiforme
- Neutrophilic urticarial dermatosis
- Acquired angioedema

LABORATORY TESTS

The most common abnormal laboratory results associated with urticarial vasculitis (UV) include:

- Elevated erythrocyte sedimentation rate (ESR)
- Hypocomplementemia (usually decreased C1q, C3, and C4)
- Circulating immune complexes by the C1q solid phase test and/or anti-C1q antibody assay
- Positive antinuclear antibodies (ANA)
- Antidouble stranded DNA (ds-DNA)
- Anti-Ro, -La, -Sm, and -RNP antibodies
- Antineutrophil cytoplasmic antibodies (ANCA), particularly enzyme immunoassays for antibodies to proteinase-3 and myeloperoxidase (PR3- and MPO-ANCA)
- Rheumatoid factor and/or anticyclic citrullinated peptides (anti-CCP)
- Immunofixation electrophoresis
- Cryoglobulins and cryofibrinogens

Skin biopsy: Leukocytoclasis, or fragmentation of leukocytes with nuclear debris, and fibrinoid deposits are important histopathologic findings that represent direct signs of vessel damage. Immunofluorescence reveals deposits of immunoglobulins, complement, or fibrin around blood vessels in most patients.

TREATMENT

GENERAL Rx

- UV is often difficult to treat, and therapy is based upon case reports and small series.
- Systemic glucocorticoids are considered the mainstay of therapy for UV, and additional agents are typically added.
- Antihistamines are used to manage pruritus.
- Glucocorticoids in combination with either dapsone, colchicine, or hydroxychloroquine are typically used as initial therapy for patients with mild to moderate disease.
- For patients with refractory symptoms or those with organ- or life-threatening disease manifestations, other agents in combination with glucocorticoids are recommended: mycophenolate mofetil, methotrexate, azathioprine, and cyclosporine; rarely, cyclophosphamide, rituximab, anakinra, canakinumab, and omalizumab are used.
- The assistance of a rheumatologist with experience in the management of vasculitides is suggested for patients with evidence of significant systemic disease.

DISPOSITION

- Patients with hypocomplementemia have severe disease and may experience significant morbidity and mortality; however, they rarely die as a direct result of the disease, even in the setting of multisystem involvement.
- Pulmonary involvement is a leading cause of morbidity and mortality, due largely to complications of COPD.

Hypocomplementemic Urticarial Vasculitis

REFERRAL

Rheumatology, dermatology, pulmonary critical care, cardiology, nephrology

PEARLS & CONSIDERATIONS

- UV is a clinicopathologic entity consisting of urticaria and evidence of leukocytoclastic vasculitis on skin biopsy.
- UV predominantly involves the skin but may affect other organs, particularly the lungs, kidney, and gastrointestinal tract.
- Hypocomplementemia, when present, may be associated with extensive vasculitis and systemic features.
- The pathophysiology of UV is believed to involve the deposition of immune complexes in vessel walls, complement activation, and mast cell degranulation due to C3a and C5a with resultant urticaria.
- The diagnosis of UV requires the presence of urticaria with leukocytoclastic vasculitis (LCV) on skin biopsy.
- If LCV is present, further testing is indicated to define the presence and extent of systemic disease and to evaluate for associated conditions.
- UV is a benign and self-limited disease for the majority of patients, although symptoms can last for decades in some individuals.

BASIC INFORMATION

DEFINITION

Hypoglycemia refers to abnormally low blood glucose levels in circulating plasma. It is defined as a glucose value less than 70 mg/dl (3.9 mmol/L). "Serious hypoglycemia" refers to values <54 mg/dl (3.0 mmol/L). "Severe hypoglycemia" is any glucose value necessitating external assistance to correct it. "Reactive hypoglycemia" refers to symptoms of hypoglycemia with plasma glucose value greater than 70 mg/dl. A multitude of scenarios can lead to this potentially fatal condition.

SYNONYMS

Glycopenia
Low blood glucose
Low blood sugar
HG

ICD-10CM CODES

E10.641	Type 1 diabetes mellitus with hypoglycemia with coma
E10.649	Type 1 diabetes mellitus with hypoglycemia without coma
E11.641	Type 2 diabetes mellitus with hypoglycemia with coma
E11.649	Type 2 diabetes mellitus with hypoglycemia without coma
E13.641	Other specified diabetes mellitus with hypoglycemia with coma
E13.649	Other specified diabetes mellitus with hypoglycemia without coma
E16.1	Other hypoglycemia
E16.2	Hypoglycemia, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- More frequent in type 1 diabetes mellitus (DM). Estimated that glucose levels may be as low as 50 to 60 mg/dl ~10% of the time in type 1 DM.
- HG occurrence 62 to 320 episodes per 100 patient yr in type 1 diabetes vs. 35 episodes per 100 patient yr in type 2 diabetes.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms are often nonspecific.
- Early symptoms include sweating, pallor, anxiety, palpitations, hunger, and tremor.
- Late symptoms with lower plasma glucose levels include seizures, altered mental status, and coma.
- Profound or prolonged hypoglycemic episodes can cause irreversible brain injury, cardiopulmonary arrest, and death.

ETIOLOGY

- Medications are the most common cause of hypoglycemia. Most common causes include exogenous insulin, insulin secretagogues (sulfonylureas [SU] and meglitinides [MG]), and alcohol
- Critical illness
  1. Organ failure (hepatic, cardiac, or renal)
  2. Sepsis
- Hormone deficiency (cortisol, glucagon, and epinephrine)
- Endogenous hyperinsulinism (insulinoma, functional beta-cell disorders, insulin autoimmune hypoglycemia)
- Rare fatal episodes thought to be secondary to ventricular arrhythmias

DIAGNOSIS

Characterized by Whipple triad:

- Symptoms potentially explained by hypoglycemia
- Low blood glucose levels during the symptoms
- Relief of symptoms with administration of glucose or glucagon

DIFFERENTIAL DIAGNOSIS

Hypoglycemic symptoms in the presence of normal plasma glucose levels (>70 mg/dl) point to other etiologies: Postprandial syndrome, cardiac disease, psychiatric disease, metabolic disorders (hyperthyroidism, pheochromocytoma)

WORKUP

- If Whipple triad is positive, the next step is to consider a patient's medical status.
- Iatrogenic causes are the most common causes of hypoglycemia in hospitalized patients (review the timing of glucose-lowering medications and interactions between medications).
- Detailed history, including past medical history, a thorough medication history, and timing of hypoglycemia (in regard to meals and medications).

LABORATORY TESTS

- An algorithm for recognition and evaluation of hypoglycemia is described in Fig. 1.
- If the cause is not apparent after a thorough history, the following is appropriate:

FASTING: If symptoms witnessed when fasting, with verified low blood glucose levels, draw the following labs: Plasma glucose, β-hydroxybutyrate (BHOB), insulin, C-peptide, proinsulin, screen for SU and MG metabolites.

POSTPRANDIAL:

- Plasma glucose, insulin, C-peptide, and proinsulin prior to ingestion of the meal and every 30 min thereafter for 5 hr.

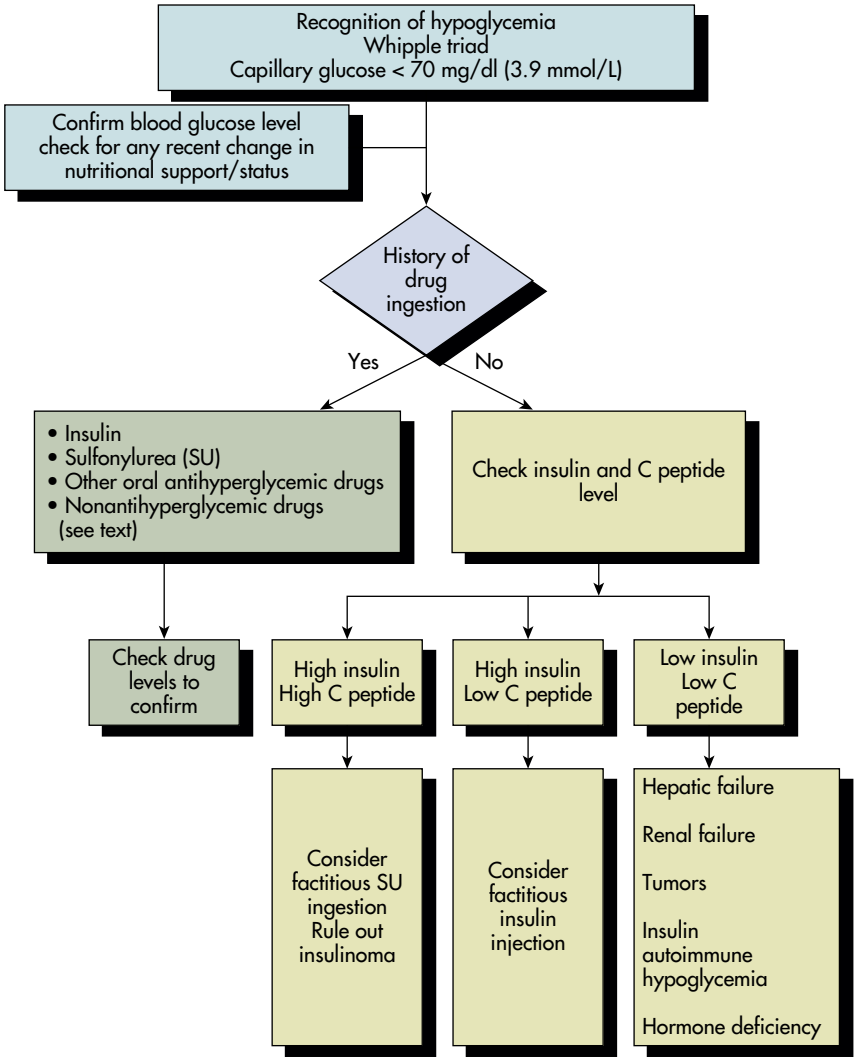

FIG. 1 Recognition and evaluation of hypoglycemia. (From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.)

- Only evaluate the samples drawn when glucose levels are <60 mg/dl.
- If a patient has a presentation consistent with Whipple triad, then measure SU, MG, and antibodies to insulin.

72-HR FAST:

- Collect blood specimens for measurement of plasma glucose, insulin, C-peptide, proinsulin, and BHOB every 6 hr until the glucose concentration is <60 mg/dl.
- Increase frequency of sampling to every 1 to 2 hr.
- Insulin, C-peptide, and proinsulin are only relevant in those specimens in which the plasma glucose concentration is <60 mg/dl.
- The fast should be ended when any of the following occurs:
  1. The plasma glucose concentration is <45 mg/dl.
  2. The patient has symptoms or signs of hypoglycemia.
  3. 72 hr have elapsed.
  4. The plasma glucose concentration is <55 and Whipple triad has been documented on a prior occasion.
- Insulin antibodies are also measured but do not need to be measured during the hypoglycemic state.

IMAGING STUDIES

If hypoglycemia is suspected secondary to an insulinoma or malignancy, transabdominal ultrasound (US), CT scan, or endoscopic US can be used to help with diagnosis as well as for staging purposes.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Recognition of signs and symptoms, and self-monitoring of blood glucose are especially important in insulin-deficient patient.
- Avoiding drugs that can exacerbate condition (e.g., alcohol) if it occurs on repeated occasions.
- Bedtime snacks if hypoglycemia occurs at night.
- In situations caused by tumor etiologies (e.g., islet cell, insulinoma, and nonislet cell), definitive treatment may require surgical removal.

PHARMACOLOGIC THERAPY

- Treating the underlying etiology that exacerbates hypoglycemia (e.g., infection, proper diabetic regimen)
- Fast-acting carbohydrates (e.g., glucose tablets, hard candy, IV dextrose infusion)
- Pure glucose (dextrose) if caused by insulin secretagogue in addition with alpha-glucosidase inhibitor
- In severe hypoglycemia with seizure activity, 25 g of 50% dextrose IV or 0.5 to 1.0 mg IM/subcutaneous glucagon
- Fig. 2 describes a management algorithm for hypoglycemia

REFERRAL

- Most scenarios of hypoglycemia can be managed by primary care physicians by adjusting medications.
- If the cause is not clear, then endocrinology referral is recommended.

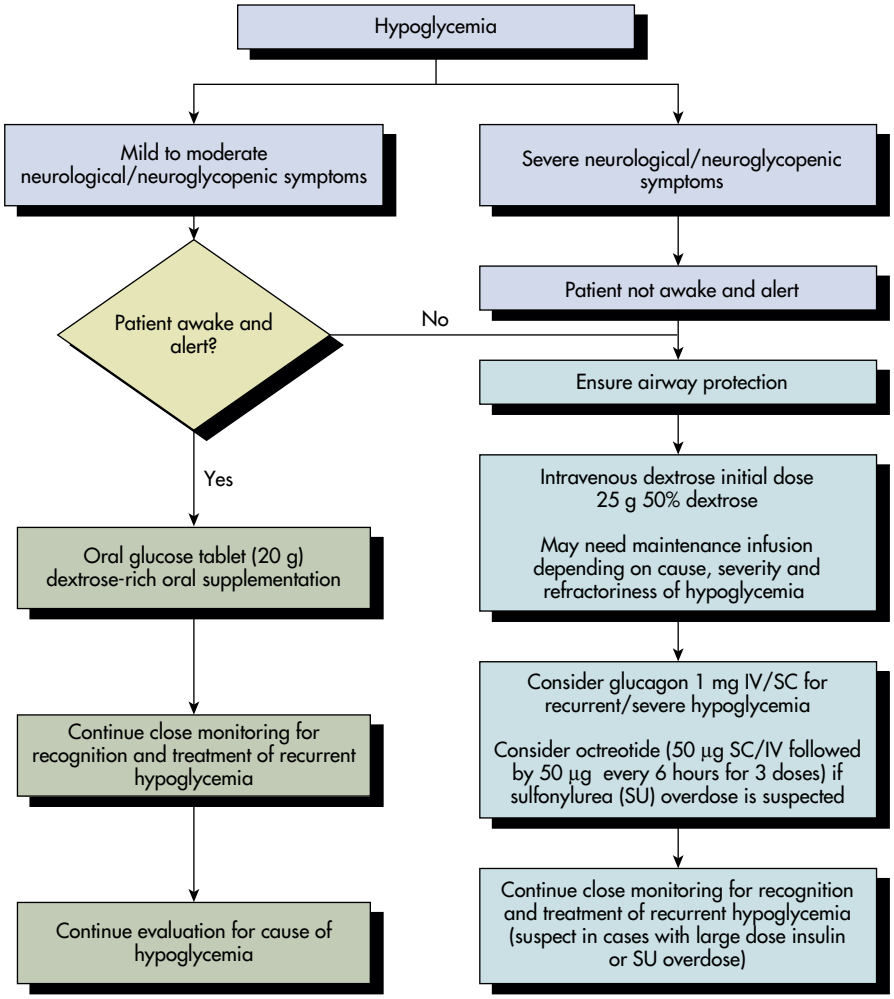

FIG. 2 Management of hypoglycemia. *IV,* Intravenous; *SC,* subcutaneous. (From Vincent JL et al: *Textbook of critical care,* ed 7, Philadelphia, 2017, Elsevier.)

PEARLS & CONSIDERATIONS

- Hypoglycemia can cause severe morbidity and death if not dealt with promptly and effectively.
- Hypoglycemia is very common in patients with DM, especially type 1 DM, and most commonly it is a side effect of medications.
- In patients who are hospitalized, the etiology is often multifactorial.
- Clinically important hypoglycemia is uncommon in nondiabetic patients, and evaluation for a hypoglycemic disorder in these patients should only occur if the Whipple triad is met.

BASIC INFORMATION

DEFINITION

Male hypogonadism is a clinical syndrome involving subnormal testosterone levels and/or impaired sperm production due to dysfunction at one or both levels of the hypothalamic-pituitary-testicular axis.

SYNONYM

Testicular dysfunction

ICD-10CM CODES

E23.0 Hypopituitarism
E23.1 Drug-induced hypopituitarism
E29 Testicular dysfunction
E29.1 Testicular hypofunction
E29.8 Other testicular dysfunction
E29.9 Testicular dysfunction, unspecified
E89.3 Postprocedural hypopituitarism

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Hypogonadism is the most common clinical disorder of the testis. Incidence is unclear due to the many possible underlying factors, nonspecificity of symptoms, and questions relating to the adequacy of a diagnostic serum total testosterone threshold.

PREVALENCE: Prevalence of hypogonadism increases with aging, obesity, diabetes mellitus, and other comorbidities. The average decrease in serum total testosterone levels in aging men is 1% to 2% per yr. Prevalence rises to 23% among men in their 70s. However, in population-based surveys of community-dwelling middle-aged and older males, prevalence of hypogonadism is approximately 6%.

GENETICS: Genetic abnormalities underlie a number of hypogonadal disorders including Klinefelter syndrome, Noonan syndrome, hemochromatosis, Kallmann syndrome, and Prader-Willi syndrome.

RISK FACTORS: These are many and include genetic abnormalities; the aging process; pituitary and testicular lesions and disorders; medications; drug abuse; HIV disease; acute illnesses; chronic cardiac, hepatic, renal, and pulmonary diseases; cancer; ionizing radiation; chemotherapy; obesity; and malnutrition.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Sexual (specific)
- Decrease in frequency of erections
- Erectile dysfunction
- Decrease in libido
- Decreased fertility
- Small or shrinking testes
- Gynecomastia
- Diminished sexual hair
- Hot flushes and sweats

Neuropsychologic (less specific)
- Depression
- Inability to concentrate
- Diminished motivation and vitality
- Decrease in self-confidence
- Diminished energy and stamina
- Sleep disturbances

Physical features and findings
- Diminished capacity for physical activity
- Decrease in physical endurance and performance
- Diminished muscle mass and strength
- Increase in body fat
- Decrease or loss of axillary and pubic hair and decrease in shaving frequency
- Fine wrinkling over the lateral aspects of the face
- Breast enlargement with or without tenderness
- Change in consistency and decrease in size of testes
- Fragility fractures
- Anemia

ETIOLOGY

- The importance of a careful history and examination cannot be overstated to determine the etiology of possible hypogonadism. Primary hypogonadism is a result of a decrease in testicular testosterone secretion and/or a decrease in spermatogenesis with an associated increase in gonadotropin levels as in Klinefelter syndrome, cryptorchidism, and following orchitis, testicular trauma, chemotherapy, and irradiation.
- Secondary hypogonadism is due to hypothalamic-pituitary dysfunction, which results in a decrease in testosterone levels and/or spermatogenesis with gonadotropin levels that are subnormal or inappropriately within the normal range.
- Combined primary and secondary hypogonadism is a result of deficits at both the level of the hypothalamic-pituitary axis and testes with variable gonadotropin levels depending upon the predominance of the level of the defect.

DIAGNOSIS (Fig. 1)

DIFFERENTIAL DIAGNOSIS

Hypogonadotropic or secondary hypogonadism
- Pituitary dysfunction: Hypopituitarism, functioning or nonfunctioning pituitary tumor, lymphocytic hypophysitis, infiltrative disease as with sarcoidosis, hemochromatosis, and histiocytosis X
- Hyperprolactinemia: Prolactinoma, medication-related, chronic kidney disease
- Genetic: Kallmann syndrome with anosmia, Prader-Willi syndrome with morbid obesity
- Acute and chronic illnesses, malnutrition, emotional disorders, HIV, sleep apnea, aging, malignancies, obesity, and renal, hepatic, pulmonary, and cardiac diseases
- Opioids, CNS: Active medications, glucocorticoid excess, and GnRH analogues (androgen deprivation therapy)

Hypergonadotropic or primary hypogonadism
- Genetic: Klinefelter syndrome, Noonan syndrome, myotonic dystrophy
- Gonadal damage due to drugs, alcohol, radiation, chemotherapy, trauma
- Congenital anorchia (vanishing testis syndrome)
- Cryptorchidism
- Mumps orchitis, HIV orchitis
- Diabetes mellitus
- Hodgkin disease
- Aging

Combined primary and secondary hypogonadism
- Hemochromatosis, sickle cell disease, thalassemia
- Alcoholism, glucocorticoid therapy, aging
- Chronic cardiac, hepatic, renal, pulmonary diseases, and HIV disease

WORKUP

- Determine the presence or absence of male hypogonadism on the basis of history, clinical manifestations and findings, and documentation of consistently low serum total testosterone levels and/or abnormal seminal fluid analysis.
- Morning serum total testosterone levels should be measured on at least 2 or 3 occasions for confirmation of diagnosis and when necessary followed by measurement of serum free or bioavailable testosterone.
- Serum follicle-stimulating hormone (FSH) and luteinizing hormone (LH) levels are measured to determine whether hypogonadism is primary, secondary, or a result of combined defects of the hypothalamic-pituitary axis and testis. The case of testosterone deficiency should be definitively determined before initiation of testosterone replacement therapy.
- Hormonal assessment of gonadal status should not be done during an acute or subacute illness.

LABORATORY TESTS

- Serum total testosterone is tightly bound to sex hormone binding globulin (SHBG) and weakly bound to circulating albumin. 0.5% to 3% of serum total testosterone is unbound or free.
- Liquid chromatography tandem mass spectrometry assays for total serum testosterone are more accurate than immunoassays.
- Bioavailable testosterone refers to unbound testosterone plus the testosterone that is loosely bound to albumin.
- Free testosterone, if necessary, is best measured by equilibrium dialysis or centrifugal ultrafiltration.
- An SHBG measurement is helpful in determining the adequacy or normality of a serum total testosterone measurement. Conditions that lower SHBG include obesity, protein-losing states, androgens, hypothyroidism, and familial SHBG deficiency. Increases in SHBG occur in those with hyperthyroidism, hepatitis, cirrhosis, and HIV disease, aging, and by estrogens.
- The lower limit of normal for serum total testosterone in a healthy young male is approximately 240 to 950 ng/dl and a low-normal serum free testosterone in a young normal male is 5 to 20 ng/dl.
- Serum total testosterone levels can vary from day to day and there is a diurnal rhythm in young normal males with morning levels that are higher by approximately 20% to 25% as compared with levels in the afternoon.

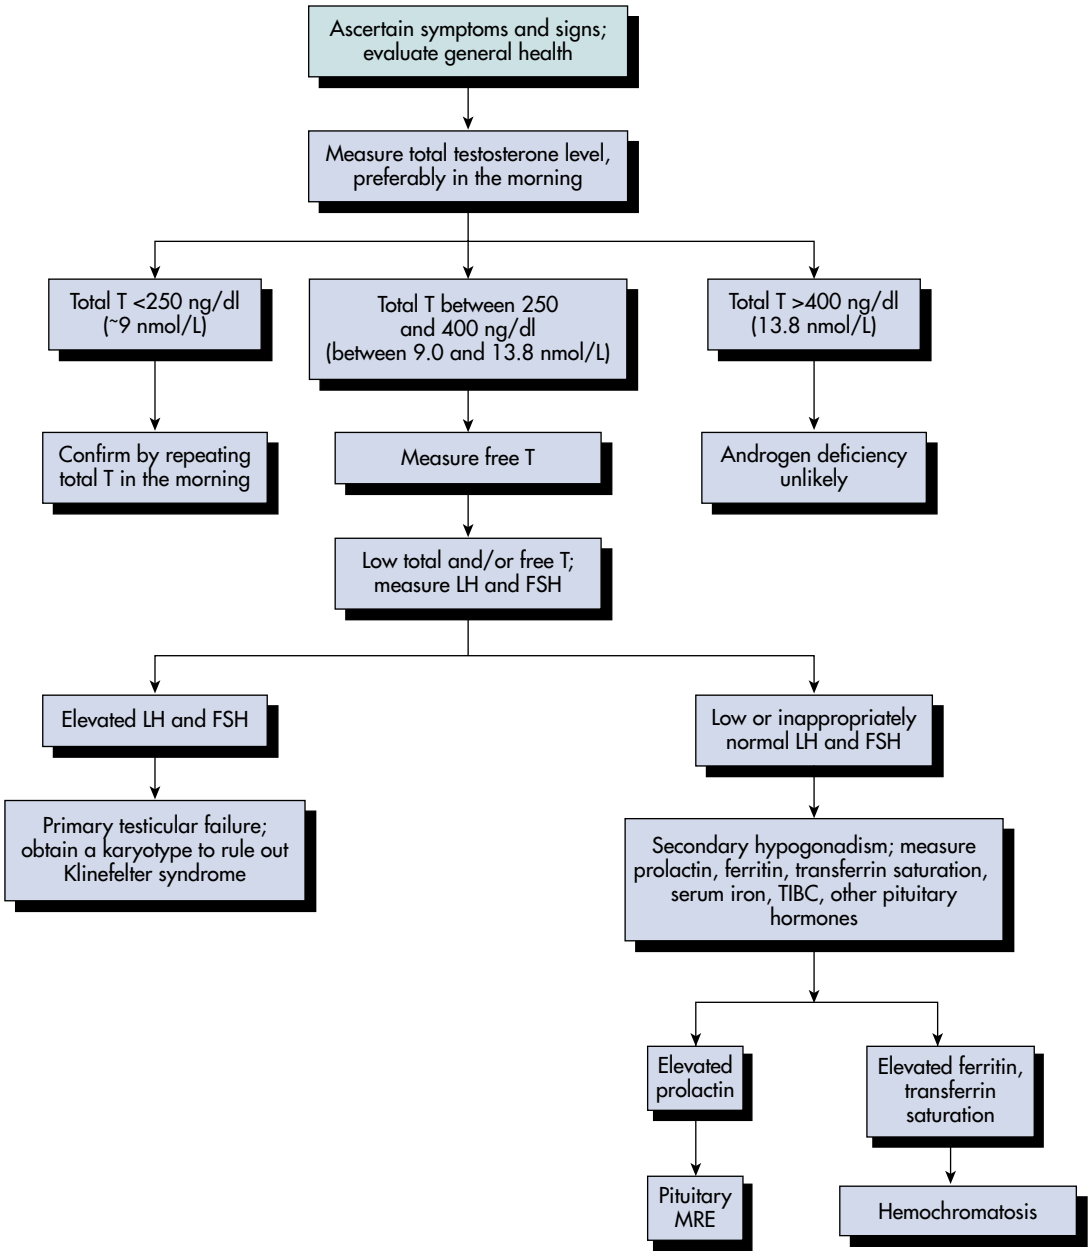

FIG. 1 Algorithm showing an approach for the diagnostic evaluation of adult men suspected of having androgen deficiency. *FSH,* Follicle-stimulating hormone; *LH,* luteinizing hormone; *T,* testosterone; *TIBC,* total iron-binding capacity. (From Shalender B, Shehzad B: Diagnosis and treatment of hypogonadism in men, *Best Pract Res Clin Endocrin* 25:251-270, 2011.)

- In elderly males, the diurnal rhythm is diminished with levels approximately 10% lower in the afternoon as compared with morning levels.
- Serum FSH and LH measurements are important in delineating primary, secondary, and combined hypogonadism.
- Hypogonadal symptoms are more likely to be seen in those with total serum testosterone level below the lower limit of values for young normal males. Serum total testosterone levels of <150 ng/dl are unequivocally low.
- Transient suppression of total serum testosterone may occur during acute illness, in males that are being treated with glucocorticoid, in those taking opiates or CNS-active medications, in those with malnutrition or poor eating habits, and during excessive physical exercise.
- Quantity and quality of sperm counts and activity can vary in a significant way for a variety of reasons. Therefore, in assessing fertility, seminal fluid analysis should be done on two or more occasions, each separated by 2 or more wk, and on semen collected within an hour of ejaculation after more than 2 days of abstinence.
- Depending on the clinical picture and examination, other studies may be necessary, including a karyotype analysis, for example, for Klinefelter syndrome, or serum prolactin measurement for patients with possible hyperprolactinemia, which may be drug-induced, related to a prolactinoma, or to chronic renal disease.

IMAGING STUDIES

In males with severe androgen deficiency with low serum gonadotropin levels, increased serum prolactin levels, hypopituitarism, severe headaches, and visual defects, an MRI of the pituitary would be appropriate. In males with hypogonadism and a history of fractures, dual energy x-ray absorptiometry (DXA) measurements of spine and hip should be obtained to further delineate the status of the skeletal system.

Rx TREATMENT

Testosterone replacement therapy is indicated when patients have symptoms and signs of hypogonadism and serum testosterone levels

that are consistently subnormal with levels of <250 ng/dl. The goal of replacement therapy is to restore serum testosterone levels to within the normal range of values and to have a positive effect on the constellation of hypogonadal symptoms and signs. Subnormal spermatogenesis, if present in such patients, is not affected by testosterone therapy. In patients with hypogonadotropic or secondary hypogonadism, chorionic gonadotropin and/or GnRH therapy can optimize spermatogenesis, whereas, generally in patients with primary hypogonadism, subnormal spermatogenesis and infertility are irreversible.

NONPHARMACOLOGIC THERAPY

- Weight reduction, especially when it appears to be a major factor underlying male hypogonadism
- Discontinuation of anabolic steroids, CNS-active medications, and narcotic abuse
- Surgery or radiation therapy for patients with a pituitary functioning or nonfunctioning tumor with visual field abnormality and headaches who are not candidates for further medical therapy or have been unsuccessfully treated with medication
- Surgery indicated for chronic gynecomastia and, occasionally, in cases with recent-onset gynecomastia that has not responded to testosterone replacement therapy

CHRONIC Rx

Testosterone formulations:

- Parenteral testosterone preparations: Testosterone enanthate (generic) and testosterone cypionate (Depo-Testosterone and generic) 150 to 200 mg are injected intramuscularly every 2 wk. Following injections, there are appreciable fluctuations in serum testosterone, with levels rising within the first several days and a subsequent decrease to normal and in some cases to below normal at the end of the 2 wk. As a result of the varying levels of testosterone, patients may have related symptoms. Adjustments in dose and dosing interval may help to alleviate the serum fluctuations and clinical symptoms. Testosterone undecanoate (AUEFD-ENDO) is an injectable depot formulation FDA-approved for male hypogonadism. The recommended dosage is 750 mg injected IM at 0 and 4 wk, and then every 10 wk thereafter.
- Topical testosterone preparations:
  1. Testosterone adhesive patch (Androderm) delivers 2.5 or 5 mg of testosterone when applied nightly to the back, abdomen, upper arms, or thighs. Serum testosterone levels rise to within normal range in a few hours after application and, thereafter, are relatively stable. Daily doses of up to 10 mg may be necessary.
  2. Testosterone 1% gels (AndroGel and Testim). AndroGel is available in 2.5 g and 5 g gel units that deliver 2.5 mg and 5 mg of testosterone, respectively. The gel is applied daily in the morning by hand over the shoulder, upper arms, or abdomen. Adjustments in dose to 7.5 g or 10 g of gel may be necessary to optimize serum testosterone levels. AndroGel (1.62%) pump is also available for daily application. Testim is available in 5-g and 10-g tubes and with morning applications over the shoulders or arms delivers 5 mg and 10 mg of testosterone, respectively. Both AndroGel and Testim provide relatively stable serum testosterone levels. Two new transdermal formulations, Fortesta and Axiron, are now available and are applied daily by metered dose pumps. With these preparations, care is necessary to avoid skin-to-skin contact exposure with others.
- Testosterone pellets: 3 to 6 pellets of testosterone each containing 75 mg of testosterone are surgically inserted subcutaneously every 3 to 6 mo and provide relatively stable serum testosterone levels.

RISKS & ADVERSE EFFECTS

- Contraindications to testosterone therapy include prostate cancer and breast cancer. Relative contraindications include severe benign prostatic hyperplasia, hematocrit ≥50% at baseline, sleep apnea, and severe congestive heart failure.
- Patients on chronic testosterone therapy need to be followed carefully with prostate and prostate-specific antigen (PSA) assessments and hematocrit measurements for possible excessive induction of erythrocytosis, initially at 3 to 6 mo and at regular intervals thereafter.
- Current testosterone use for 6 mo or shorter is associated with 63% higher risk for venous thromboembolism (VTE). VTE risk peaks during the first 6 mo and declines to 25% thereafter.[1]

REFERRAL

Endocrinology for full endocrine and metabolic assessment and therapy. Urology for further assessment and follow-up of the prostate and for evaluation and therapy of erectile dysfunction. Neurosurgery for evaluation and possible surgery for a pituitary lesion. Plastic surgery for chronic gynecomastia. Reproductive endocrinology for those with an infertility problem.

[1]Martinez C et al: Testosterone treatment and risk of venous thromboembolism: population based case-control study, *BMJ* 355:596-598, 2016.

PEARLS & CONSIDERATIONS

COMMENTS

- Do not screen men "routinely" for hypogonadism. Screening men with nonspecific symptoms of hypogonadism (e.g., decreased energy) is also not recommended. Screening should be limited to men with specific signs and symptoms of hypogonadism.
- Male hypogonadism is an important and frequently encountered problem that requires a complete medical history, examination, and hormonal assessment to determine whether a patient has hypogonadism and requires testosterone replacement therapy. Treated patients need to be seen on a regular basis to avoid possible testosterone adverse effects. Patients requiring testosterone replacement should have testosterone, prostate specific antigen, and hematocrit levels monitored.
- Trials to evaluate the effects of testosterone treatment in older men revealed that in symptomatic men 65 yr of age or older, raising testosterone concentrations for 1 yr from moderately low to the mid-normal range had a moderate benefit with respect to sexual function and some benefit with respect to mood and depressive symptoms but no benefit with respect to vitality or walking distance.[2]
- Controversy exists regarding the safety of testosterone replacement therapy following reports of increased risk of cardiovascular events. However, a recent trial among men with androgen deficiency dispensed testosterone prescriptions revealed lower risk of cardiovascular outcomes over a median follow-up of 3.4 yr.[3]
- Clinical trials have also demonstrated that testosterone replacement in men with low testosterone increases volumetric bone mineral density (vBMD) and estimated bone strength more in trabecular than peripheral bone and more in the spine than the hip.[4]

SUGGESTED READINGS

Hypokalemic Periodic Paralysis

BASIC INFORMATION

DEFINITION

Hypokalemic periodic paralysis (HPP) constitutes a variety of disorders resulting in the common pathway of muscle ion channel defects, resulting in painless muscle weakness. Total-body muscle weakness may occur periodically with either a true potassium deficit or, more commonly, a potassium shift intracellularly.

SYNONYMS

Periodic paralysis
Hypokalemic nonperiodic paralysis
Cavare disease
HPP

ICD-10CM CODE
G72.3 Familial periodic paralysis (Cavare's disease)

EPIDEMIOLOGY & DEMOGRAPHICS

- HPP has an incidence of 1:100,000.
- Autosomal-dominant inheritance.
- One third of cases are new mutations.
- Most new cases develop in patients with thyrotoxicosis.
- Anderson syndrome is a rare variant of HPP and has an incidence of 1:1,000,000. Patients are at risk for cardiac arrhythmias because the potassium-channel mutation is also expressed in cardiac muscle.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Usual onset is during adolescence as transient episodes of generalized weakness without muscle-tone loss following exercise or carbohydrate intake.
- Attacks usually last several hours but can last up to days.
- Attacks may be provoked by rest after vigorous exercise, stress, or high-carbohydrate meals. The resulting increase in epinephrine and/or insulin leads to an intracellular shift of potassium and low serum potassium.
- Attacks have also been known to be provoked by cold, alcohol, lack of sleep, emotional stress, beta-2 receptor agonists, diuretics, corticosteroids, insulin, glucocorticoids, viral illness, menstruation, and pregnancy.
- Legs are generally affected more than arms, and proximal more than distal muscles.
- Most commonly symptoms occur in the morning after waking.
- Ocular, bulbar, and respiratory muscles are spared.

ETIOLOGY

- Caused by mutations in transmembrane voltage-gated ion channels of the skeletal muscle or endoplasmic reticulum.
- Most common mutation is in the alpha-1 subunit of the dihydropyridine-sensitive calcium channel in skeletal muscle. Exact mechanism for causing hypokalemia is not currently known.
- The final common pathway is low extracellular potassium concentration. This causes a transient membrane depolarization, which inactivates voltage-gated sodium and calcium channels. These channels are no longer capable of generating action potential essential for muscular contraction.

DIAGNOSIS

- Hypokalemia during an attack and the exclusion of alternative syndromes is sufficient to establish the diagnosis.
- Serum potassium will normalize between attacks in HPP.
- If there is familial history of HPP, no further diagnostic tests apart from hypokalemia during an attack are necessary.

DIFFERENTIAL DIAGNOSIS

- Hyperkalemic periodic paralysis
- Normokalemic periodic paralysis
- Thyrotoxicosis
- Myasthenia gravis
- Secondary hypokalemia unrelated to channelopathy
- Anderson syndrome
- Guillain-Barré syndrome
- Transverse myelitis
- Tick paralysis
- Botulism
- Barium poisoning

WORKUP

Serum potassium levels establish the diagnosis and guide treatment.

LABORATORY TESTS

- Mean serum potassium level during attacks has been reported as 2.4 mmol/L.
- T3, T4, TSH levels to exclude thyrotoxic periodic paralysis resulting from hyperthyroidism.
- Rule out secondary causes of hypokalemia (thyrotoxicosis, diuretic use, vomiting, diarrhea, hyperaldosteronism, distal tubular renal acidosis).
- Serum electrolyte measurement.
- Genetic testing is available for the majority of common mutations.
- Provocative testing with ACTH, exercise, or insulin and glucose are high-risk options when genetic testing does not produce results.
- Electromyography may help distinguish the etiology of hypokalemia during an attack.

OTHER TESTS

EKG may demonstrate ST depression, T wave depression, increased U wave. Arrhythmias are uncommon with HPP but have been reported.

TREATMENT

ACUTE GENERAL Rx

- Potassium chloride, 60 to 120 mEq PO given in increments of 15 to 30 every 20 to 30 min is usually sufficient to relieve acute attacks.
- PO potassium is preferred to IV form.
- Carbonic anhydrase inhibitors, specifically acetazolamide and dichlorphenamide, have shown utility in relieving symptoms. However, there is potential for exacerbating hypokalemic attack in patients with diabetes via intracellular potassium shift.

CHRONIC Rx

- Patients may develop chronic progressive proximal myopathy around age 50 yr. Most pronounced in proximal upper and lower extremities as well as pelvic girdle.
- Frequency of attacks and weakness begin to decrease around age 50 yrs.
- Avoidance of potassium-lowering pharmaceuticals, high-carbohydrate foods, bicarbonate and potassium-lowering diuretics, and strenuous physical exercise has been demonstrated to prevent attacks.
- Some patients may need potassium supplements, potassium-sparing diuretics, and carbonic anhydrase inhibitors chronically to maintain sufficient serum potassium levels to prevent attacks.

DISPOSITION

- Patients treated with oral potassium are at risk for hyperkalemia following an attack as intracellular potassium redistributes into the extracellular space. Potassium levels may be monitored intermittently for 24 hr after treatment.
- Patients with new-onset hypokalemia or suspected new-onset HPP may be admitted for further diagnostic workup.

PEARLS & CONSIDERATIONS

Serum potassium levels reflect extracellular potassium, which is only 2% of total body potassium stores. Low serum potassium levels during an attack typically represent intracellular shift rather than total-body depletion.

BASIC INFORMATION

DEFINITION

Magnesium (Mg), after potassium, is the second most abundant intracellular and fourth most cation in living organisms. This ion plays a vital role in nearly every major metabolic and biochemical process within cells. Magnesium is a critical cofactor of the ubiquitous cellular Na^+-K^+-ATPase and is notable to have coexisting secondary electrolyte disorders when deranged. Serum magnesium concentration is tightly regulated by a dynamic balance among three organ systems: Gut, kidney, and bone. Most of the total body magnesium is found in bone, muscle, and skin. Serum magnesium represents only 0.3% of the total body magnesium. Magnesium has been implicated in and used as treatment for several diseases. Although its importance is widely acknowledged, routine serum magnesium levels are generally not evaluated in clinical medicine.

Magnesium deficiency is defined as a decrease in total body magnesium content. The recommended daily allowance of magnesium is 420 mg for males and 320 mg for females. Fig. 1 illustrates magnesium homeostasis in healthy adults. Magnesium is mainly absorbed through the jejunum and ileum. Poor dietary intake of magnesium usually does not lead to severe magnesium deficiency because normal kidney function prevents magnesium loss through renal conservation of magnesium maintaining homeostasis. Fig. 2 depicts the renal handling of magnesium by the kidney. Hypomagnesemia is typically defined as a total serum magnesium concentration below 1.8 mg/dl and is categorized as mild (1.5 to 1.8 mg/dl), moderate (1 to 1.4 mg/dl), or severe (<1 mg/dl). Serum magnesium levels do not fully correlate with total body magnesium levels given that the different compartments that magnesium is found in do not easily equilibrate like sodium does. Thus normal magnesium levels in patients where hypomagnesemia would be expected may still need magnesium supplementation, such as in cases of hypocalcemia, hypokalemia, or malnutrition.

SYNONYMS

Magnesium deficiency
Low magnesium

ICD-10CM CODES

E83.40 Disorders of magnesium metabolism, unspecified
E83.42 Hypomagnesemia

EPIDEMIOLOGY & DEMOGRAPHICS

Hypomagnesemia has been estimated to occur in more than 10% of hospitalized patients and is especially common among the critically ill, with an incidence as high as 65%. It may be encountered in 25% to 35% of patients with acute pancreatitis. Low magnesium levels frequently are encountered in chronic alcoholics and poorly controlled diabetics. The incidence and prevalence of hypomagnesemia are similar across sexes, races, and ethnicities, but may be greater in the elderly. This observation may be explained by poorer nutritional intake, greater use of certain medications (e.g., diuretics, laxatives, proton pump inhibitors), or comorbidities.

RISK FACTORS

- Alcoholism
- Volume expansion (including pregnancy)
- Poorly controlled diabetes mellitus
- Chronic diuretic use
- Chronic laxative use
- Chronic use of proton pump inhibitors
- Subarachnoid hemorrhage
- Severe sepsis
- Acute phase after liver transplantation
- Large transfusions with citrate-rich blood products
- Postsurgical patients
- Leptospirosis
- Pancreatitis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Mild hypomagnesemia is most frequently asymptomatic. Clinical manifestations appear with more severe deficiency.
- Signs and symptoms are not unique and frequently difficult to determine if caused by hypomagnesemia or its complications of hypokalemia or hypocalcemia.
- Symptoms of hypomagnesemia have been reported at modest degrees of depletion, but generally they are more common when serum magnesium levels fall below 1.2 mg/dl.
- Neuromuscular effects include weakness, cramps, and paresthesias. Manifestations may include Trousseau and Chvostek signs. More severe depletion can cause vertical nystagmus, tetany, and seizures.
- Metabolic effects include hypokalemia from renal potassium wasting that may be refractory to potassium supplementation until magnesium deficiency is repaired. Hypocalcemia is also common in hypomagnesemia, which suppresses release of parathyroid hormone (PTH), and end-organ resistance to PTH with low 1, 25 vitamin D levels may occur.
- Cardiovascular effects: Hypomagnesemia is associated with a variety of atrial and ventricular arrhythmias.
- ECG findings: Flattened T-waves, prolonged QT interval, ST depression, and widened QRS complexes and concerns for *torsades de pointes*.
- The role of magnesium deficiency in the clinical development of seizures and cardiac arrhythmias requires treatment of these conditions with magnesium.

ETIOLOGY

Causes (Table 1)

DIAGNOSIS

WORKUP

- Comprehensive history including medication and dietary history, alcohol use, prior magnesium measurements, and history of disorders associated with hypomagnesemia (e.g., disorders of gastrointestinal tract, vomiting, diarrhea)
- Physical examination and review of vital signs, intake, and output

LABORATORY TESTS

The total serum concentration of magnesium should be measured in hospitalized patients with acute illness to screen for hypomagnesemia. This is indicated for critically ill patients

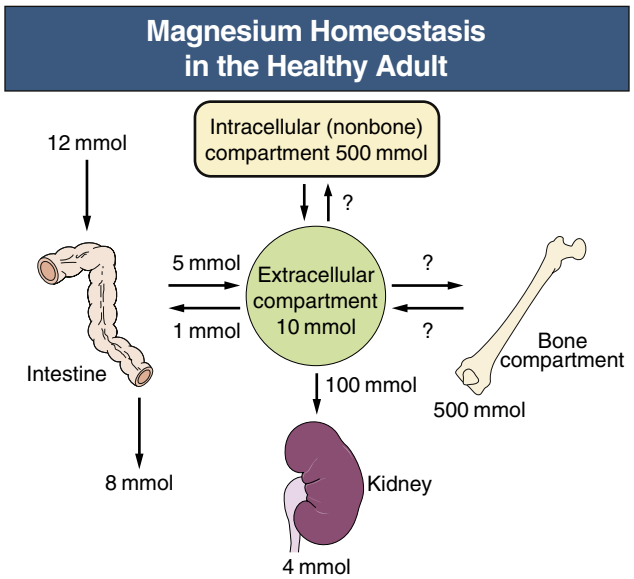

FIG. 1 Magnesium homeostasis in healthy young adults. Net zero balance results from net intestinal uptake (absorption minus secretion) equaling urinary loss. After its passage into the extracellular fluid, Mg^{2+} enters the intracellular space and is deposited in bone or soft tissue or eliminated via the kidneys. Entry and exit fluxes between the extracellular and intracellular spaces (skeletal and nonskeletal compartments) are also of identical magnitude; however, precise values of exchange are still debated. (From Johnson RJ: *Comprehensive clinical nephrology,* ed 6, Philadelphia, 2019, Elsevier.)

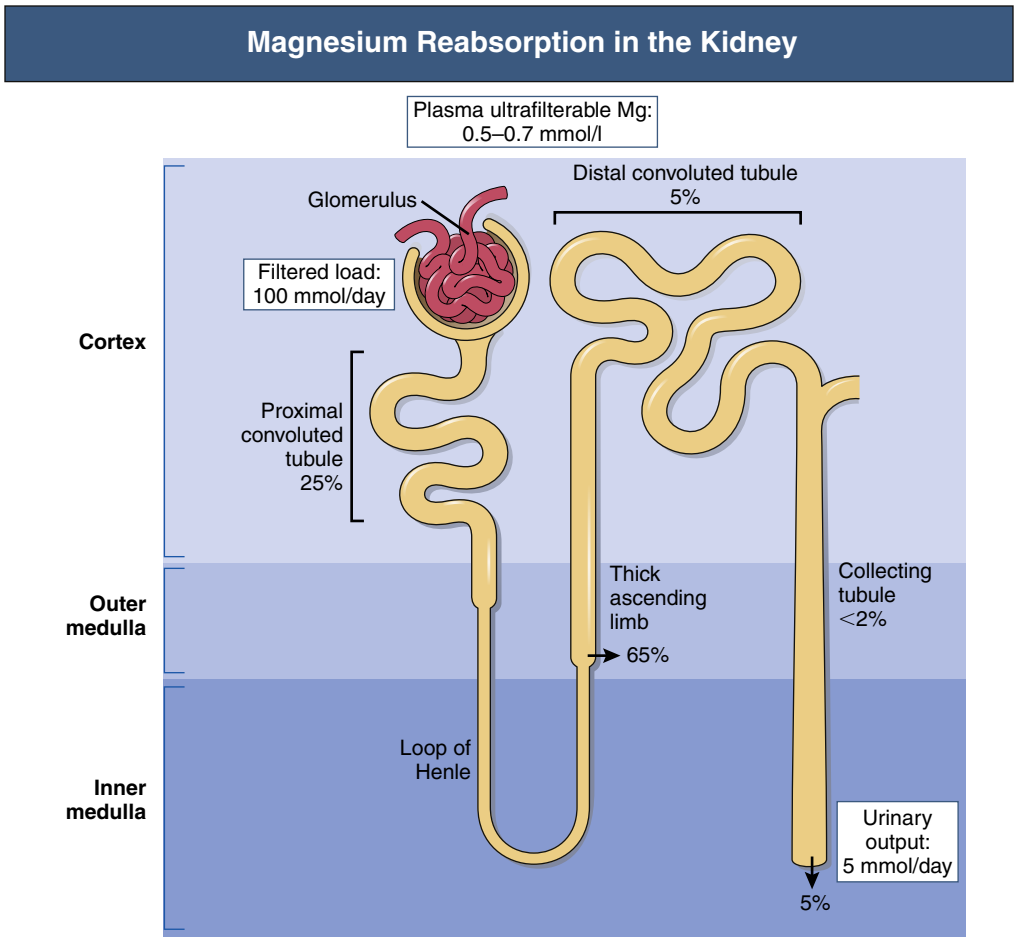

FIG. 2 Sites of magnesium reabsorption in various segments. Percentage absorbed in various segments of the renal tubule from the glomerular ultrafiltrate. (Redrawn from Quamme GA: Control of magnesium transport in the thick ascending limb, *Am J Physiol* 256:F197-F210, 1989. In Johnson RJ: *Comprehensive clinical nephrology,* ed 6, Philadelphia, 2019, Elsevier.)

and those deemed at risk of cardiac arrhythmias or seizures. Although the ionized fraction of serum magnesium (typically two-thirds of the total concentration) is the physiologically active form of the cation, measurement of serum ionized magnesium is not recommended because this measurement does not influence clinical management. The etiology of magnesium deficiency is often obvious from the history. When the cause is unknown, the fractional excretion of magnesium (FE_{Mg}) may facilitate diagnosis. With extrarenal magnesium loss from malabsorption or laxative abuse, the FE_{Mg} should be appropriately reduced (<4%). If FE_{Mg} exceeds 4%, renal magnesium wasting is present, often secondary to surreptitious diuretic use or familial magnesium-wasting disorders.

IMAGING STUDIES

Not routinely recommended

Rx TREATMENT

It is unclear whether mild, asymptomatic hypomagnesemia requires treatment. However, symptomatic hypomagnesemia is treated with intravenous magnesium, typically magnesium sulfate. For treatment of *torsades de pointes,* 1 to 2 g of intravenous magnesium sulfate as a bolus over 5 minutes is recommended.

Magnesium repletion in patients with acute or chronic renal insufficiency must be carried out cautiously. Evaluation for depressed deep tendon reflexes, periodic monitoring of serum magnesium levels, and dose reductions from 50% to 75% are recommended.

Oral magnesium supplementation may treat mild cases of hypomagnesemia successfully. In the outpatient setting, oral magnesium salts such as magnesium oxide (250 to 500 mg four times daily) can be used for repletion. However, these agents frequently cause diarrhea, particularly at high doses. Patients with gastrointestinal magnesium-wasting who do not achieve normal levels of repletion with one formulation may respond to an alternative formulation. Potassium-sparing diuretics may be used for renal magnesium-wasting states, provided hyperkalemia does not occur. Intravenous magnesium supplementation causes an abrupt rise in serum magnesium levels, which leads to reduced reabsorption of magnesium by the kidneys in patients with normal renal function and will limit magnesium repletion. In most cases, oral supplementation of magnesium should suffice.

DISPOSITION

- Potential contributing factors should be evaluated and treated appropriately.
- Patients with symptomatic or severe hypomagnesemia require monitoring in an intensive care setting until the serum magnesium concentration and associated electrolyte abnormalities are corrected and stabilized at safe levels.
- The risk of recurrence depends primarily on the nature of the underlying disorder. Hypomagnesemia has less chance of recurrence if the offending medication is discontinued and/or when gastrointestinal and renal losses are not chronic. Inherited disorders may necessitate prolonged supplementation.
- In patients with self-limited reasons for magnesium deficiency, repletion therapy can be accomplished easily. However, in patients with persistent magnesium wasting, treatment by oral magnesium therapy may not correct the serum level to normal. Nevertheless, these individuals adapt to their chronic hypomagnesemia and tolerate it fairly well.

REFERRAL

- Outpatient referral to nephrology or endocrinology may be indicated to help manage

TABLE 1 Causes of Magnesium Deficiency

Poor intake	Dietary deprivation or malnutrition
	Insufficient magnesium in tube-feeding formulas
	Parenteral nutrition preparations with insufficient magnesium
Redistribution of magnesium from extracellular to intracellular space or bone	Treatment of diabetic ketoacidosis
	Refeeding syndrome
	Hungry bone syndrome following parathyroidectomy
	Correction of metabolic acidosis
	Acute and chronic pancreatitis (soft tissue sequestration and gastrointestinal loss)
	Severe burns (sequestration in necrotic tissue)
	Hyperthyroidism
Poor intestinal absorption/increased intestinal loss	Diarrhea
	Inflammatory bowel disease (*e.g.*, Crohn disease, ulcerative colitis)
	Intestinal fistula
	Laxative use
	Nasogastric suction
	Proton pump inhibitor administration
	Severe malabsorption
	Short bowel syndrome
	Steatorrhea
Excessive renal loss	Diuretics:
	Loop diuretics (loss of magnesium and calcium)
	Thiazide-like diuretics (loss of magnesium with calcium retention)
	Hypercalciuria
	Metabolic acidosis
	Osmotic diuretics (hypertonic solutions)
	Poorly controlled diabetes and diabetic ketoacidosis (especially during recovery phase after phosphorus replacement)
	Primary hyperaldosteronism
	Renal tubular acidosis
	Syndrome of inappropriate antidiuretic hormone secretion (SIADH)
	Other drugs:
	Aminoglycosides
	Amphotericin B
	Cisplatin, carboplatin
	Cyclosporine
	Foscarnet
	Monoclonal antibodies that target the epidermal growth factor receptor (*e.g.*, cetuximab, panitumumab)
	Pentamidine
	Tacrolimus
Inherited causes	Autosomal-dominant hypocalcemia with hypercalciuria (ADHH)
	Bartter syndrome
	Familial hypomagnesemia with hypercalciuria and nephrocalcinosis
	Gitelman syndrome
	Hypomagnesemia with secondary hypocalcemia (HSH)
	Isolated dominant hypomagnesemia
	Isolated recessive hypomagnesemia

patients with chronic hypomagnesemia that does not warrant hospital admission.
- Inpatient referral to specialists in nephrology, endocrinology, and /or critical care medicine is recommended in cases of severe or symptomatic hypomagnesemia.
- Consultation with a dietitian can help increase dietary magnesium intake and protein supplementation in malnourished patients.

PEARLS & CONSIDERATIONS

COMMENTS

Serum magnesium measurement is the most available and most commonly employed test to evaluate magnesium status.

Routine correction of underlying etiologies and electrolyte and metabolic derangements is recommended for hypomagnesemia while increasing dietary magnesium intake and/or supplementing magnesium. Chronic hypomagnesemia may be associated with various micro- and macrovascular complications.

BASIC INFORMATION

DEFINITION

Hyponatremia is defined as a measured serum sodium concentration (S_{Na}) less than the lower limit of normal (i.e., <130 to135 mmol/L). Since the clinical manifestations of hyponatremia are due to hypotonicity, appropriate clinical management depends on correctly distinguishing between most patients with hypotonic hyponatremia from patients who are hypertonic or isotonic or who have pseudohyponatremia (low measured S_{Na} due solely to laboratory artifact). For this chapter, hyponatremia will be used synonymously with hypotonic hyponatremia. Pseudohyponatremia and hypertonic/isotonic hyponatremia will be identified specifically by those names.

SYNONYMS

Low serum sodium concentration
Hypoosmolality

ICD-10CM CODE
E87.1 Hypo-osmolality and hyponatremia

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: The prevalence of hyponatremia varies widely according to setting and population age. In the general U.S. population dataset of the National Health and Nutrition Examination Survey (NHANES), the overall prevalence was 1.72%. One study of emergency department patients reported a prevalence of 2.3% in patients 16 to 21 yr and 16.9% in patients >80 yr. Following surgery for traumatic hip fracture, the incidence of moderate (<135 mmol/L) and severe (<130 mmol/L) postoperative hyponatremia was 27% (95% CI, 21.7% to 32.5%) and 9% (95% CI, 5.7% to 12.8%), respectively. The prevalence in stable, older outpatients has been reported to be approximately 8% and as great as 18% to 20% in sick or frail populations. The overall incidence at or during hospital admission is comparable, with even higher rates in patients admitted for congestive heart failure (CHF), cirrhosis, or elderly patients admitted for fragility fracture.

PREDOMINANT SEX AND AGE: Prevalence of hyponatremia was significantly higher in women in the NHANES dataset (2.09%; *P*=0.004) and increased with age.

GENETICS: The hyponatremic disorder, nephrogenic syndrome of inappropriate antidiuresis (NSIAD), is caused by rare familial gain-of-function mutations of the arginine vasopressin receptor-2. Activation of a mutated receptor located in the renal collecting duct produces overt hyponatremia in infancy.

RISK FACTORS: In NHANES, hyponatremia was more common in subjects with hypertension, diabetes, coronary artery disease, stroke, chronic obstructive pulmonary disease, cancer, and psychiatric disorders, and less common in those with no comorbidities (1.04%, *P* <0.001). A significant risk of death was associated with hyponatremia in unadjusted Cox models (hazard ratio [HR], 3.61; *P* <0.001) and adjusted (HR 2.43; *P* <0.001). The incidence in outpatients using thiazide diuretics was 15.1%, with an HR of 4.95 (95% CI, 4.12 to 5.96). Reported frequencies of hyponatremia of outpatients using selective serotonin reuptake inhibitors (SSRIs) or selective norepinephrine reuptake inhibitors (SNRIs) has varied widely between 0.5% and 32%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Critical history includes detailed documentation of fluid consumption and diet, gastrointestinal and insensible losses of fluid and electrolytes, urine outputs, changes in weight, medication use, changes in behavior or cognition. Recent medical procedures involving irrigation of tissue beds (e.g., transurethral prostatectomy or hysteroscopy with endometrial resection), participation in marathons or other strenuous endurance exercise or attendance at "rave" parties where illicit use of 3,4-methylenedioxymethamphetamine (MDMA, "Ecstasy") is common should be noted. Comorbid conditions that increase the risk of hyponatremia include malignancy, CNS or pulmonary disease, adrenal or thyroid disease, CHF, liver disease, or nephrotic syndrome.
- The etiology of hyponatremia may affect the clinical presentation both directly and/or by its effect on the extracellular fluid volume (ECFV). Hypovolemia and hypervolemia (decreased or increased ECFV, respectively) are identified by conventional clinical criteria. If available, vector bioimpedance analysis has been shown to further increase accuracy. Specific manifestations of the precipitating cause or underlying diseases may be evident (e.g., fever and delirium following the use of MDMA, stigmata of alcoholism or malnutrition, fever and/or localizing symptoms related to pneumonia or other pulmonary disease, or headaches and visual field defects from an intracranial mass).
- Neurologic symptoms predominate as the direct clinical manifestations of hyponatremia due to cerebrocyte swelling. Compensatory processes that reduce cerebral edema by extrusion of electrolytes, amino acids, and carbohydrates from brain cells take 24 hours to become fully active and up to 7 days to reach completion. Therefore, patients who develop hyponatremia over less than 24 to 48 hours have the highest degree of brain swelling, the most severe neurologic symptoms, and greatest risk of permanent or fatal brain injury. Post-pubertal, premenopausal women appear to undergo cerebral compensation more slowly, placing them at greater risk from acute hyponatremia.
- Acute hyponatremia may result in nausea and malaise as S_{Na} becomes 130 mmol/L or less. Headache, lethargy, obtundation, neurogenic pulmonary edema, and/or seizures may occur when the S_{Na} is <120 mmol/L. In the most severe cases, death from brain stem herniation can occur.
- Chronic hyponatremia almost never presents with life-threatening clinical manifestations. However, subtler neurologic disturbances such as ataxia, short-term memory deficits, fatigue, lethargy and nausea have been commonly reported. Muscular weakness and elevated creatine kinase and even rhabdomyolysis may occur. Chronic hyponatremia has also been associated with increased risk of falls, fractures, and osteoporosis in elderly patients. In addition, hyponatremia has been associated with increased risk of cardiovascular complications and mortality in a diverse group including elderly outpatients, general hospital admissions, and patients admitted for stroke, subarachnoid hemorrhage, CHF, cirrhosis, pneumonia, hip fracture and liver transplantation.

ETIOLOGY

- In patients with hypotonic hyponatremia, S_{Na} is closely approximated by the ratio, $(TBNa_e + TB_K)/TBW$ (TB_{Na} and TB_K are total body compartments of exchangeable sodium and potassium, respectively; TBW represents total body water). Hypotonic hyponatremia results from decreases of the numerator, increases of denominator, or both. TB_{Na} is the main determinant of ECFV.
- ECFV depletion (with proportionately greater decrease in TBNa and possibly TBK than in TBW).
  1. GI losses with intake of hypotonic fluids
  2. Renal losses (diuresis, tubulopathies) with intake of hypotonic fluid
  3. Cerebral salt wasting
- Normovolemic (normal ECFV and TB_{Na}).
  1. Syndrome of inappropriate antidiuresis (SIAD; see "Syndrome of Inappropriate Antidiuresis")
  2. Medications (thiazide diuretics, SSRIs and SNRIs, narcotics, MDMA/"Ecstasy," carbamazepine, cyclophosphamide, nicotine, DDAVP, phenothiazines, terlipressin)
  3. Pain, nausea, stress
  4. Marathon running or other endurance exercise
  5. Primary polydipsia
  6. Solute-limited water excretion (tea-and-toast diet, beer potomania)
  7. Severe potassium deficiency with normal total body sodium
  8. Adrenal insufficiency or hypothyroidism
  9. Reset osmostat
- Hypervolemic (increased ECFV and TB_{Na}) with decreased effective arterial blood volume (EABV). Hyponatremia results from proportionately greater increase in TBW than in TB_{Na} and TB_K.
  1. CHF
  2. Nephrotic syndrome
  3. Cirrhosis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- *Pseudohyponatremia.* Clinical laboratories report and to some extent measure the concentration of sodium (mmol) per liter of

plasma, not plasma water. Consequently, conditions (severe hypertriglyceridemia, hypercholesterolemia and hyperproteinemia) that significantly reduce the aqueous fraction of plasma (normally 0.93) may lead to a decrease in the reported S_{Na} despite the presence of serum normal osmolality (S_{osm}). However, since the condition can coexist with preexisting hypernatremia or hypotonic hyponatremia that also affects S_{osm}, a more reliable method for identifying the disorder is the presence of an increased serum osmolal gap (i.e., difference between measured and calculated serum osmolalities is >10 mOsm/kg H_2O) and a low S_{Na}. Calculated $S_{osm\ (mOsm/L)} = 2 \times S_{Na}$ (mmol/L) + S_{Glu} (mg/dl)/18 + BUN (mg/dl)/2.8. In brief, pseudohyponatremia is isotonic hyponatremia.

- *Hypertonic hyponatremia.* Small solutes such as glucose (in the absence of insulin), mannitol, and sorbitol accumulate in higher concentrations in the ECF than ICF and shift water from the ICF to ECF compartment. Since the ICF is virtually sodium free, the ECF sodium concentration declines producing hyponatremia. In the case of glucose, a decrease in S_{Na} of 1.6 mmol/L occurs for each increment of serum glucose of 100 mg/dl. The property of a solute to shift fluid from ICF to ECF is known as tonicity, which is of clinical importance because increases and decreases in tonicity also result in brain cell shrinkage and edema, respectively. In contrast, solutes such as urea or ethanol that equilibrate across cell membranes increase total serum osmolality (measured by freezing point depression) but neither tonicity nor S_{Na}.

WORKUP

- Comprehensive history including medication and drug abuse history, psychiatric history, exercise history, prior serum sodium measurements, dietary history, history of external fluid losses, volume and composition of oral and IV fluid intake, and history suggestive of disorders associated with hyponatremia (e.g., disorders of the lungs, CNS, heart, kidney, liver, adrenal gland, or thyroid; malignancies; diabetes mellitus; nausea; vomiting; pain; or stress)
- Comprehensive physical examination including careful review of vital signs, weights, intake and outputs; evidence of increased ECFV (e.g., edema, ascites, or pleural effusions) or depletion and evidence of comorbid diseases listed previously (e.g., abnormal pulmonary, neurologic or cardiovascular exam, hepatomegaly, thyromegaly or nodular thyroid)

LABORATORY TESTS

- Serum glucose to adjust for influence on serum sodium (serum sodium decreases approximately 1.6 mmol/L for every additional 100 mg/dl increase in serum glucose).
- Serum potassium: Because $S_{Na} = (TB_{Na} + TB_K)/TBW$, decreases in TB_K lower S_K and S_{Na}.
- Random urine osmolality and 24-hour urine volume. U_{osm} <100 mOsm/kg H_2O usually indicates appropriate suppression of ADH, suggesting diagnoses of solute-limited water excretion, primary polydipsia, or a reset osmostat (if S_{Na} is below the patient's altered setpoint). U_{osm} ≥100 mOsm/kg H_2O usually implies the presence of ADH. However, U_{osm} ~290 mOsm/kg is seen in patients using loop diuretics while even higher osmolalities can be seen during osmotic diuresis. The latter is characterized by total urine osmolar excretion >900 mOsm/day), while in both cases urinary ([Na] + [K]) ~60 to 90 mmol/L.
- Random urine sodium (U_{Na}), and urine potassium (U_K). U_{Na} <20 mmol/L suggests either decreased ECFV or decreased EABV. U_K must be considered when prescribing and monitoring therapy (see the following).
- Specific testing for comorbid diseases listed previously as clinically indicated (e.g., fasting morning cosyntropin-stimulated serum cortisol level, BNP, and TSH).

IMAGING STUDIES

- Not routinely required. Computed tomography or magnetic resonance imaging may be indicated to diagnose associated etiologies or evaluate associated delirium that may be present in acute hyponatremia.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Hyponatremic patients excrete less electrolyte-free water than input. Moderate fluid restriction (10 to 15 ml/kg) is indicated while patients are hyponatremic, especially if free water excretion capacity remains impaired. Diets high in protein, sodium, and potassium increase urine osmolar generation, thereby increasing free water excretion.

ACUTE GENERAL Rx

- Acute (hypotonic) hyponatremia is defined as developing over <24 hours. Acute hyponatremia results in larger increases in brain water than equivalent changes in S_{Na} developing over longer durations due to lack of cellular adaptation to hypotonic stress. Consequently, correction of acute hyponatremia is a medical emergency and mandates an increase in S_{Na} of 4 to 6 mmol/L within the initial 1 to 3 hours of therapy, depending on severity of symptoms and acuity of S_{Na} elevation. Iatrogenic cases, classically children or premenopausal women receiving perioperative hypotonic fluids, are fortunately rare now. These circumstances can present with headache or nausea prior to severe symptoms and require emergent correction. Acute hyponatremia is rare in patients with high ECFV because the increased TB_{Na} partially offsets the decreased $(TB_{Na} + TB_K)/TBW$ ratio, due to the increased TBW.
- Controlled increases of S_{Na} at this rapid rate nearly always requires hypertonic (3%) saline. The recommended rate of correction in severe acute hyponatremia is an increase in S_{Na} of 4 to 6 mmol/L in the first hour. In normovolemic patients (i.e., having normal TB_{Na}), furosemide 20 to 40 mg IV has been used in conjunction with hypertonic saline to lessen the expansion of ECFV while maintaining the rapid increase in S_{Na} by increasing free water excretion.
- Regardless of the therapies employed, patients with acute hyponatremia require monitoring in an ICU setting with frequent measurements of S_{Na}, urine volume, and U_{osm} until patients are neurologically stable and the S_{Na} approaches the lower normal range.

CHRONIC Rx

- Chronic hyponatremia develops over >24 to 48 hours, during which time brain cell adaptation occurs by the extrusion of electrolytes and organic osmolytes such as amino acids. Consequently, the possibility of cerebral edema is minimized while the risks of rapid correction increase. Precipitous increases in S_{Na} in this setting have been associated with demyelinating injuries. The appropriate target for correction of hyponatremia in this setting is 6 to 8 mmol/L per day.
- In hypovolemic patients with chronic hyponatremia the usual clinical practice is to administer 0.9% saline until patients are normovolemic. The 0.9% saline results in very little direct change in S_{Na} because it increases total body cation and TBW proportionately, but indirectly can eventually trigger a rapid increase in S_{Na} after patients become normovolemic and ADH is suppressed. The simultaneous use of desmopressin (1 to 2 mcg IV every 12 hours) is a recommended adjuvant to therapy in these patients to postpone the risk of overly rapid correction until the patient is clinically normovolemic and IV fluids may be discontinued, and the patient monitored. If the rate or magnitude of S_{Na} correction starts exceeds recommended targets, desmopressin may be re-dosed as needed. Desmopressin may provide protection against overly rapid elevations of S_{Na} in patients with unrecognized solute-limited water diuresis (see later).
- The risk of overly rapid correction is highest in hyponatremic patients with tea-and-toast diets or beer potomania. These patients are recognized primarily by a U_{osm} < 100 mOsm/kg H_2O, thereby demonstrating suppression of ADH. The preferred treatment of this situation is fluid restriction and dietary supplementation to supply appropriate quantities of protein and electrolytes. Reflex administration of IV saline is contraindicated: 1 L of IV 0.9% saline (308 mOsm/L) supplies enough osmoles to excrete 3 to 6 L of hypotonic urine in the absence of ADH. If saline has already been given, rapid urinary water loss may be blunted by desmopressin.
- The treatment of normovolemic patients is covered in detail in the "Syndrome of Inappropriate Antidiuresis" and thus is only briefly reviewed here. The goal of therapy in these patients is to reduce TBW in controlled fashion maintaining TBNa and TBK. Some patients with chronic normovolemic

hyponatremia (e.g., drug-induced etiologies or primary polydipsia) have self-limited abnormalities and primarily require monitoring to prevent excessively rapid correction. Active therapy as described below can be started to avoid delays. If required, desmopressin can be administered intermittently to temporarily block further losses of free water to slow the overall rate of correction. If overcorrection has occurred oral and/or IV hypotonic fluids may be quantitatively administered to lower the serum sodium actively. Other disorders may only slowly resolve and require more active therapy as delineated in "Syndrome of Inappropriate Antidiuresis," consisting of either a direct V2 receptor antagonist or a loop diuretic combined with replacement of electrolytes lost during diuresis.

DISPOSITION

- Patients with symptomatic or severe hyponatremia require monitoring in an ICU setting until the S_{Na} has stabilized at a safe level. Frequent monitoring of serum sodium, urine volume, and urine osmolality and electrolytes is required, with adjustments in therapy as outlined previously as needed.
- All potential contributing causes should be evaluated and treated appropriately. Aside from obvious disorders, less apparent conditions such as adrenal insufficiency and hypothyroidism should be ruled out.
- The risk of recurrence depends primarily on the nature of the underlying disorders present. Hypovolemic hyponatremia (e.g., diarrheal or diuretic-induced electrolyte and water losses) or drug-induced SIAD may have little chance of recurrence if the offending medication is discontinued or if gastrointestinal losses are not chronic. Elderly patients with solute-limited diuresis due to low electrolyte and protein intake may be resistant to major changes in diet but may agree to NaCl tablets and/or protein supplements. In addition to disease-specific management, incurable conditions (e.g., chronic CNS or pulmonary disease, CHF, or cirrhosis) may require life-long fluid restriction (10 to 15 ml/kg/day), high protein and electrolyte diets as tolerated, and periodic monitoring of the S_{Na} to reduce the risk of recurrence.

REFERRAL

- Referral to specialists in nephrology, endocrinology, and/or critical care medicine are recommended in cases of severe or symptomatic hyponatremia to aid in setting appropriate rates of correction and to recommend, monitor, and adjust therapeutic regimens to achieve those target rates.
- Outpatient referral to nephrology or endocrinology may be required to facilitate the management of patients with mild hyponatremia or recurrent hyponatremia that does not warrant hospitalization.

PEARLS & CONSIDERATIONS

COMMENTS

PREVENTION: Well-meaning family members, friends, news media, and health care providers often encourage patients with chronic kidney disease or who are taking diuretics to drink large amounts of water. When these patients consume more free water than they can excrete, hyponatremia may develop. Similarly, participants in marathons or other high-intensity endurance activities may ingest so much water that in place of TBW depletion they develop high TBW and hyponatremia. Patients at risk for hyponatremia should receive a specific fluid prescription that avoids both extremes. Conversely, patients with diarrheal losses or who develop decreased ECFV from loop diuretics or combination diuretics must be counseled that intake of water or other hypotonic fluids alone will lead to hyponatremia but not effectively restore ECFV. Safe outpatient correction of ECFV requires the consumption of electrolyte-containing solutions such as those marketed for infants. A more recent alternative is the use of commercial electrolyte tablets or packets. Standard sports drinks have high sugar content but relatively low quantities of electrolytes and may be inadequate for electrolyte replacement.

BASIC INFORMATION

DEFINITION

A decrease in parathyroid hormone (PTH) secretion or function results in hypoparathyroidism. In **primary hypoparathyroidism,** absence or dysfunction of the parathyroid gland results in inadequate PTH secretion and subsequent hypocalcemia and hyperphosphatemia. Surgical hypoparathyroidism is the most common etiology, followed by autoimmune disorders. Individuals with autoimmune polyglandular syndrome 1 typically present in childhood/adolescence with candidiasis, hypoparathyroidism, and adrenal insufficiency. Impaired function of PTH (i.e., PTH resistance) can also cause hypocalcemia and hyperphosphatemia, but the measured PTH level is elevated in this circumstance. A maternally transmitted mutation in the *GNAS1* gene results in PTH resistance (i.e., pseudohypoparathyroidism). It is associated with characteristic features that include developmental delay, short stature, round facies, and short 4th metacarpal known as Albright hereditary osteodystrophy (AHO). Paternal transmission manifests with AHO without PTH resistance (i.e., pseudopseudohypoparathyroidism; Table 1). **Secondary hypoparathyroidism,** a condition in which PTH levels are low in response to hypercalcemic states, is discussed in Section IV (see hypercalcemia discussion in the "Calcium" topic).

ICD-10CM CODES

E20.0	Idiopathic hypoparathyroidism
E20.1	Pseudohypoparathyroidism
E20.8	Other hypoparathyroidism
E20.9	Hypoparathyroidism, unspecified
E89.2	Postprocedural hypoparathyroidism
P71.4	Transitory neonatal hypoparathyroidism

EPIDEMIOLOGY & DEMOGRAPHICS

The incidence and prevalence of primary hypoparathyroidism depends on the etiology of the condition. Estimated prevalence in the United States is between 23 to 37 cases per 100,000 person-yr. Postoperative hypoparathyroidism is the most common etiology (75%). This occurs in the setting of thyroid or parathyroid surgery as a result of removal of, or vascular compromise of, the parathyroid glands during surgery. Transient hypoparathyroidism (<6 mo) can be as high as 20% postoperatively, but permanent dysfunction (>6 mo) is less common (3%). Autoimmune disorders are the second most common cause of hypoparathyroidism in adults (female/male ratio of 1.4:1.0). Autoimmune polyglandular syndrome type I is reported to have an incidence worldwide of 1:1,000,000. Other etiologies of hypoparathyroidism are very rare.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The symptoms of hypoparathyroidism are primarily related to hypocalcemia. The presentation of symptoms varies with the severity and duration of illness.

- Cardiovascular: Prolonged QT intervals, QRS and ST segment changes, ventricular arrhythmias
- Musculoskeletal: Muscle cramps, laryngospasm, osteomalacia (adults), rickets (children), weakened tooth enamel, osteosclerosis
- CNS: Tetany (Chvostek sign and Trousseau sign), seizures, paresthesias, visual impairment from cataract formation, altered mental status, papilledema, and basal ganglia calcifications with longstanding disease
- GI: Abdominal pain
- Renal: Hypercalciuria and nephrolithiasis
- Other: Dry scaly skin, brittle nails, dry hair

In addition to the hypocalcemia-related symptoms, syndromes associated with hypoparathyroidism can have distinct clinical findings. Conditions associated with hypoparathyroidism include:

- Autoimmune polyglandular syndrome type 1: Mucocutaneous candidiasis and adrenal insufficiency
- DiGeorge syndrome: Dysmorphic facies, cleft palate
- Pseudohypoparathyroidism: Developmental delay, short stature, round face, short fourth metacarpal (Albright hereditary osteodystrophy)
- Hypoparathyroidism-retardation-dysmorphism syndrome: Short stature, microcephaly, microphthalmia, small hands and feet, abnormal teeth
- Hypoparathyroidism-deafness-renal dysplasia syndrome: Sensorineural deafness
- Kenny-Caffey syndrome: Short stature
- Kearns-Sayre syndrome: Paralysis of eye muscles and pigmentary retinopathy

ETIOLOGY

There are several etiologies of hypoparathyroidism:

- Postoperative hypoparathyroidism; most common cause (78% of cases)
- Destruction of the parathyroid glands:
  1. Autoimmune polyglandular syndrome type 1
  2. Radiation to the neck
  3. Infiltrative diseases (e.g., metastatic carcinoma, Wilson disease, hemochromatosis, thalassemia, granulomatous disease)
- Developmental defects of the parathyroid glands:
  1. Isolated hypoparathyroidism
  2. Branchial dysembryogenesis (DiGeorge syndrome)
  3. Hypoparathyroidism-retardation-dysmorphism syndrome
  4. Hypoparathyroidism-deafness-renal dysplasia syndrome
  5. Mitochondrial dysfunction associated with hypoparathyroidism
  6. Kearns-Sayre syndrome
  7. Mitrochondrial encephalomyopathy with lactic acidosis and stroke-like episodes (MELAS) syndrome
  8. Mitochondrial trifunctional protein (MTP) deficiency syndrome
- Functional and secretory defects of the parathyroid glands:
  1. Activating mutation of the calcium-sensing receptor alters the set point of the receptor and decreases PTH secretion
  2. Activating antibodies to calcium-sensing receptor alters the set point of the receptor and decreases PTH secretion
  3. PTH resistance (i.e., target organs unresponsive to PTH action)
     a. Pseudohypoparathyroidism (PHP): Heterogeneous disorder presenting in childhood characterized by hypocalcemia, hyperphosphatemia, and elevated PTH levels. Table 2 summarizes the various types of PHP
     b. Hypermagnesemia and hypomagnesemia

TABLE 1 Types of Hypoparathyroidism

Type	Calcium	PO_4	PTH	Comments
Hypoparathyroidism	↓	↑	↓	Surgical removal (most common cause)
Pseudohypoparathyroidism	↓	↑	Ø↑	End-organ resistance to parathyroid hormone and Albright hereditary osteodystrophy
Pseudo-pseudohypoparathyroidism	Normal	Normal	Normal	Only Albright hereditary osteodystrophy

PO_4, Phosphate; *PTH,* parathyroid hormone.
(Adapted from Weissleder R et al: *Primer of diagnostic imaging,* ed 5, St Louis, 2011, Mosby.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Secondary hypoparathyroidism as a result of hypercalcemia.
- Other conditions associated with hypocalcemia. These conditions are usually associated with an elevated PTH hormone level.

WORKUP

- Hypoparathyroidism is characterized by hypocalcemia and hyperphosphatemia as a result of inadequate PTH secretion.
  1. Two measurements of serum calcium are required for the confirmation of hypocalcemia. Total calcium should be corrected for low albumin utilizing the formula: Corrected calcium = measured calcium + [(4 – albumin) × 0.8]. If a reliable laboratory is available, ionized calcium should be considered especially in conditions associated with acid-base disturbances or low albumin states.

TABLE 2 Types of Pseudohypoparathyroidism (PHP)

Disorder	Urinary cAMP Response to PTH	Urinary PO_4 Response to PTH	Other Hormonal Resistance	AHO	Pathophysiology
PHP type 1A	Decreased	Decreased	Yes	Yes	$G_s\alpha$ mutation
Pseudo-PHP	Normal	Normal	No	Yes	$G_s\alpha$ mutation
PHP type 1B	Decreased	Decreased	No	No	*GNAS1* imprinting mutations
PHP type 1C	Decreased	Decreased	Yes	Yes	$G_s\alpha$ activity normal
PHP type 2	Normal	Decreased	No	No	Vitamin D deficiency or myotonic dystrophy in some cases

AHO, Albright hereditary osteodystrophy; *cAMP*, cyclic adenosine monophosphate; *GNAS1,* portion of the *GNAS* complex locus encoding $G_s\alpha$; $G_s\alpha$, α-subunit of the stimulatory G protein; PO_4, phosphate; *PTH*, parathyroid hormone.
(From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, Saunders.)

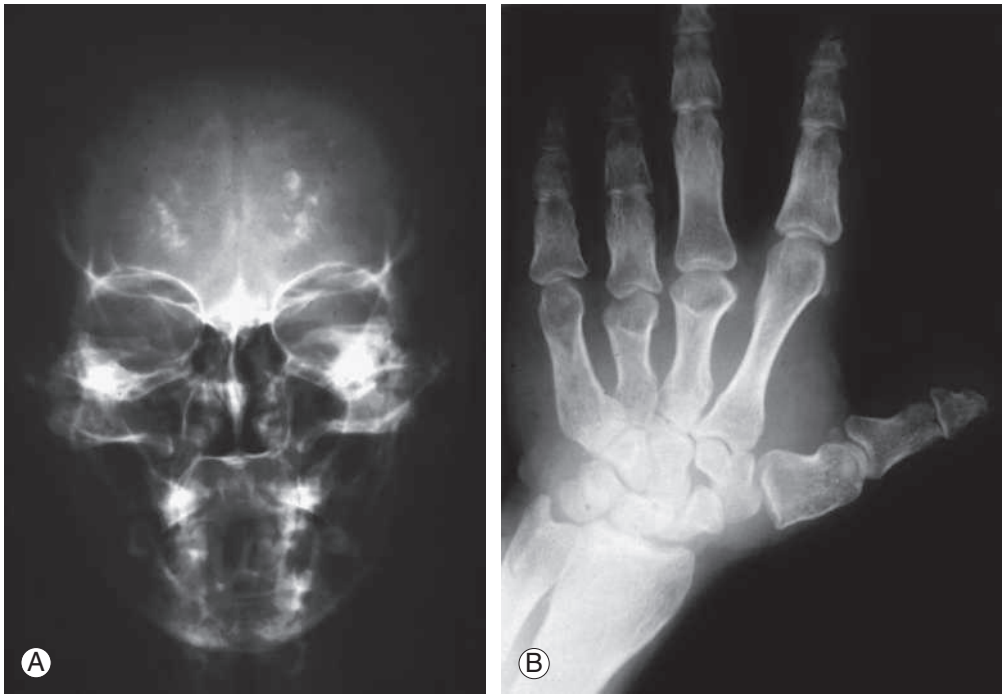

FIG. 1 Hypoparathyroidism. (A) Soft tissue calcification may be present, seen here in the basal ganglia. **(B)** In pseudohypoparathyroidism there are shortened metacarpals, particularly the 4th and 5th. (From Adam A, Dixon AK, Grainger RG, Allison DJ: *Grainger & Allison's diagnostic radiology,* 5e. Churchill Livingstone, 2007, in Grant LA: *Grainger & Allison's diagnostic radiology essentials,* ed 2, 2019, Elsevier.)

2. Serum phosphorus is usually high-normal or elevated in primary hypoparathyroidism.
3. Serum intact PTH (iPTH) level is the single best test to evaluate the etiology of hypocalcemia. Typically, PTH is low or inappropriately normal in primary hypoparathyroidism and elevated in most other conditions associated with low calcium levels. However, PTH is also elevated in disorders associated with impaired PTH function (i.e., pseudohypoparathyroidism). Genetic studies as indicated if medical or family history is suggestive.

The diagnosis is established by concurrent measurements of ionized calcium or corrected calcium that is within the lower limit of normal range and low or undetectable levels of PTH on two separate occasions at least 2 wk apart.

LABORATORY TESTS

- Total and ionized calcium: Low in hypoparathyroidism
- PTH: Low in hypoparathyroidism and high in PTH resistance states like pseudohypoparathyroidism
- Phosphorus: High-normal or high in hypoparathyroidism
- Magnesium: Both hypomagnesemia and hypermagnesemia can cause hypoparathyroidism
- 24-hr urine calcium and creatinine to evaluate the risk for renal stones
- ECG should be considered. Hypocalcemia is associated with prolonged QT interval, rarely ST-segment elevations

IMAGING

- Renal ultrasonography to detect the presence of nephrocalcinosis
- Soft tissue calcifications may be noted on plain x-rays (Fig.1)

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Diet:

- Consumption of calcium-enriched food (i.e. dairy)
- Restriction of phosphate intake (i.e. commercially prepared foods)

Parathyroid autotransplantation:

- Hypoparathyroidism and subsequent hypocalcemia are common problems after neck exploration for total or near-total thyroidectomy or parathyroidectomy. In cases where there is concern for postoperative hypoparathyroidism, parathyroid autotransplantation of one or two parathyroid glands into the forearm or sternocleidomastoid muscle should be performed to prevent postoperative hypoparathyroidism.

PHARMACOLOGIC THERAPY

The mainstay of treatment for primary hypoparathyroidism is pharmacologic therapy with calcium and vitamin D supplementation. The goals of therapy are to control symptoms and minimize complications of therapy. The aim should be to achieve low-normal serum calcium level (8.0 to 8.5 mg/dl), high-normal serum phosphorus level, 24-hr urinary calcium <300 mg/day, and a calcium-phosphorus product $<55\ mg^2/dl^2$.

- Vitamin D:
  1. There are several vitamin D preparations available on the market, but the treatment of choice for patients with primary hypoparathyroidism is calcitriol. It is an active metabolite that does not require hydroxylation in the liver or kidney and therefore bypasses the PTH-mediated 1-α hydroxylation defect that occurs with hypoparathyroidism.
  2. Dose of 0.25 to 1 μg once or twice daily is usually required to correct hypocalcemia and improve symptoms. Its maximal effect is seen after 10 h and it lasts for 2 to 3 days.
  3. High doses of vitamin D_2 (ergocalciferol) or vitamin D_3 (cholecalciferol) may also be used.
- Calcium:
  1. Calcium carbonate or calcium citrates are common oral agents used for treatment of hypocalcemia associated with hypoparathyroidism. Calcium carbonate contains 40% elemental calcium, and calcium citrate contains 21% elemental calcium. Calcium carbonate requires an acidic environment for effective absorption, and as a result, it must be taken with food. Its effectiveness is decreased with concomitant use of H_2 blockers or proton pump inhibitors. Calcium citrate does not require an acidic environment for effective absorption.
  2. Start with a dose of 500 to 1000 mg of elemental calcium two to three times daily and adjust the dose for a desired calcium in the low-normal range.
- Magnesium:
  1. Hypocalcemia is difficult to correct without normalizing magnesium levels.
  2. Magnesium sulfate IV 2 g over 20 min followed by 1 g/hr infusion can be considered in severe deficiency states. Milder deficiencies can be managed with oral magnesium 100 mg three times a day.
- Thiazide diuretics:
  1. Thiazide diuretics (25 to 100 mg daily) decrease urine calcium excretion and decrease kidney stones. They should be considered in individuals with urine calcium >250 mg/day.
- PTH replacement:
  1. Injectable synthetic human PTH (1-84) decreases urinary calcium excretion and maintains serum calcium in the normal range with reduced requirements for calcium and vitamin D supplementation.
  2. PTH (1-84, Natpara, an 84-amino acid single-chain polypeptide identical to native parathyroid hormone) is the first FDA-approved product for use in the treatment of hypoparathyroidism as an adjunct to calcium and vitamin D. PTH (1-84) is recommended for patients who cannot be well controlled on conventional therapy alone. The cost for a 4-wk supply of Natpara exceeds $7000.

ACUTE GENERAL Rx

Severe and/or symptomatic hypocalcemia requires hospitalization. Acute management of hypocalcemia includes:

- Telemetry monitoring for arrhythmias associated with severe hypocalcemia
- IV infusion of calcium gluconate 10 ml of 10% solution to receive a bolus of 90 mg of elemental calcium followed by an infusion of 0.5 to 2 mg/kg/hr until calcium levels are in the low-normal range

PEARLS & CONSIDERATIONS

COMMENTS

- The mainstay of treatment for primary hypoparathyroidism is calcitriol and calcium supplementation to maintain a goal serum calcium level in the low-normal range. IV calcium should be considered if calcium <7.0 mg/dl.
- Treatment of hypothyroidism is commonly associated with hypercalciuria, nephrocalcinosis, nephrolithiasis, and renal insufficiency. It is recommended to target blood calcium levels to the lower end of the normal range in order to reduce hypercalciuria. Urinary calcium levels should also be monitored periodically.
- Hypomagnesemia causes functional, reversible parathyroid hypofunction. Magnesium levels should be assessed and appropriately replaced in all patients with hypocalcemia before a low PTH level is attributed to hypoparathyroidism.
- In patients undergoing neck exploration, consideration should be given to the parathyroid glands. Autotransplantation of one or more parathyroid glands should be considered when appropriate to prevent postoperative hypoparathyroidism.

Hypopituitarism (PTG)

BASIC INFORMATION

DEFINITION

Hypopituitarism (from the Latin *pituita,* meaning "phlegm") is the deficiency of one or more of the hormones of the anterior or posterior pituitary gland resulting from diseases of the hypothalamus or pituitary gland. Panhypopituitarism indicates the loss of all the pituitary hormones but is often used in clinical practice to describe patients deficient in growth hormone (GH), gonadotropins, corticotropin, or thyrotropin in whom posterior pituitary function remains intact.

SYNONYMS

Panhypopituitarism
Pituitary insufficiency

ICD-10CM CODES

E23.0 Hypopituitarism
E23.1 Drug-induced hypopituitarism
E89.3 Postprocedural hypopituitarism

EPIDEMIOLOGY & DEMOGRAPHICS

Incidence of 4.2 cases per 100,000 persons

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Symptoms depend on type of onset, number and severity of hormone deficiencies, their target organs, and age of onset.

- Mass effect of a pituitary tumor can cause headaches and visual disturbances (typically as bitemporal hemianopsia).
- Rhinorrhea.
- Corticotropin deficiency:
  1. Fatigue and weakness, no appetite, abdominal pain, nausea, vomiting, failure to thrive in children, and hyponatremia. If the onset is abrupt, hypotension and shock.
- Thyrotropin deficiency:
  1. Fatigue and weakness, weight gain, cold intolerance, anemia, constipation
  2. Bradycardia, hung-up reflexes, pretibial edema, change in voice, and hair loss
- Gonadotropin deficiency:
  1. Loss of libido, erectile dysfunction, amenorrhea, hot flashes, dyspareunia, infertility, gynecomastia, decreased muscle mass, and anemia
- GH deficiency:
  1. Growth retardation in children
  2. Easy fatigue, hypoglycemia
  3. Lean mass is reduced and fat mass is increased, leading to obesity
  4. Decreased bone mineral density, increased low-density lipoprotein cholesterol, obesity, increased inflammatory cardiovascular markers (interleukin-6 and C-reactive protein)
- Hyperprolactinemia:
  1. Galactorrhea, hypogonadism, inability to lactate after delivery
  2. Posterior pituitary (vasopressin; antidiuretic hormone [ADH] deficiency): Diabetes insipidus with polyuria, polydipsia, nocturia, hypotension, and dehydration

ETIOLOGY

It can be congenital or acquired:

- Congenital: Mutations in transcription factors produce multiple hormonal deficiencies. Mutations in genes produce single hormonal deficiency.
- Acquired (Table 1): The result of destruction of pituitary cells caused by:
  1. Pituitary apoplexy: Hemorrhage or infarction of the pituitary gland. Predisposing factors include diabetes mellitus, anticoagulation therapy, head trauma, and radiation therapy. Sheehan syndrome: Postpartum necrosis, a rare complication after pregnancy.
  2. Infiltrative disease, including sarcoidosis, hemochromatosis, histiocytosis X, Wegener granulomatosis, lymphocytic hypophysitis, and infection of the pituitary (tuberculosis, mycosis, syphilis).
  3. Primary empty sella syndrome: Flattening of the pituitary gland caused by extension of the subarachnoid space and filling of cerebrospinal fluid into the sella turcica.
  4. Pituitary tumors: Classified by size (microadenomas, <10 mm; macroadenomas, >10 mm) and function. Prolactin-secreting tumors and nonfunctioning tumors account for the majority of pituitary adenomas.
  5. Suprasellar tumors: Craniopharyngiomas are the most common.

DIAGNOSIS

The diagnosis of hypopituitarism is suspected by clinical history and physical findings and is established by blood tests to confirm the presence of hormone deficiency.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis is as outlined under "Etiology."

WORKUP

Includes baseline determination of each anterior pituitary hormone followed by dynamic provocative stimulation tests, radiograph imaging, and formal visual field testing. Table 2 summarizes testing for assessment of anterior pituitary function.

LABORATORY TESTS

- Corticotropin deficiency:
  1. The presence of a 9:00 am cortisol level >20 mcg/dl or <4 mcg/dl usually confirms sufficiency or deficiency, respectively.
  2. Corticotropin stimulation test using 250 mcg of corticotropin given IV and measuring serum cortisol before and 30 and 60 min after administration. A normal response is an increase in serum cortisol level >20 mcg/dl.
  3. With pituitary disease these test results may be indeterminate, and more dynamic testing such as an insulin-tolerance or metyrapone test may be necessary.
- Thyrotropin deficiency:
  1. Thyroid-stimulating hormone (TSH) and free T_4 measurements
  2. Primary hypothyroidism shows elevated TSH with low free T_4. Secondary hypothyroidism shows normal or low TSH with low free T_4 and low T_3 resin uptake.
- Gonadotropin deficiency:
  1. Follicle-stimulating hormone (FSH), luteinizing hormone (LH), estrogen, and testosterone measurements.
  2. In men, hypogonadotropic hypogonadism is seen with low testosterone levels and normal or low FSH and LH levels (ideally measured at 9:00 A.M. because of diurnal rhythm). Check free testosterone if patient is obese.
  3. In premenopausal women with amenorrhea, low estrogen with normal or low FSH and LH levels is typically seen.
- GH deficiency:
  1. Insulin-induced hypoglycemia stimulation test using 0.1 to 0.15 unit/kg regular insulin given IV and measuring GH 30, 60, and 120 min after administration. A normal response is a GH level >3 mcg/dl. This test is contraindicated in seizure disorder or ischemic heart disease.
  2. Combination of GH-releasing hormone plus arginine is an alternative test, with a diagnostic threshold of 9 mcg/L.
  3. Because the relation between serum insulin-like growth factor (IGF)-1 and GH levels blurs with age, a normal serum IGF-1 does not exclude the diagnosis in older adults.
- Hyperprolactinemia: Prolactin levels may be elevated in prolactin-secreting pituitary adenomas.
- Vasopressin deficiency:
  1. Urinalysis shows low specific gravity.
  2. Urine osmolality is low.
  3. Serum osmolality is high.
  4. Fluid deprivation test over 18 hr with inability to concentrate the urine.
  5. Serum vasopressin level is low.
  6. Electrolytes may show hyponatremia and exclude hyperglycemia.

IMAGING STUDIES

- Imaging is the first step in identifying an underlying cause.
- MRI (Fig. E1) is more sensitive than CT in visualizing the pituitary fossa, sella turcica, optic chiasm, pituitary stalk, and cavernous sinuses. It is also more sensitive in detecting pituitary microadenomas. CT with contrast can be used if MRI is not available.
- Surveillance scan at baseline and 12 mo thereafter depending on protocol and clinical symptoms.

TABLE 1 Causes of Acquired Pituitary Insufficiency

Traumatic
- Surgical resection
- Radiation damage
- Traumatic brain injury

Infiltrative/Inflammatory
- Primary hypophysitis
- Lymphocytic
- Granulomatous
- Xanthomatous
- Secondary hypophysitis
- Sarcoidosis
- Langerhans cell histiocytosis
- Infections
- Granulomatosis with polyangiitis
- Takayasu disease
- Hemochromatosis

Infections
- Tuberculosis
- *Pneumocystis jirovecii* infection
- Fungal (histoplasmosis, aspergillosis)
- Parasites (toxoplasmosis)
- Viral (cytomegalovirus)

Vascular
- Pregnancy related
- Aneurysm
- Apoplexy
- Diabetes
- Hypotension
- Arteritis
- Sickle cell disease

Neoplastic
- Pituitary adenoma
- Parasellar mass
- Rathke cyst
- Dermoid cyst
- Meningioma
- Germinoma
- Ependymoma
- Glioma
- Craniopharyngioma
- Hypothalamic hamartoma, gangliocytoma
- Pituitary metastatic deposits
- Hematologic malignancy
- Leukemia
- Lymphoma

Functional
- Nutritional
- Caloric restriction
- Malnutrition
- Excessive exercise
- Critical illness
- Acute illness
- Chronic renal failure
- Chronic liver failure
- Hormonal
- Hyperprolactinemia
- Hypothyroidism
- Drugs
- Anabolic steroids
- Glucocorticoid excess
- GnRH agonists
- Estrogen
- Dopamine
- Somatostatin analog
- Thyroid hormone excess

Modified from Kaiser U, Ho KKY: Pituitary physiology and diagnostic evaluation. In Melmed S, et al eds: *Williams textbook of endocrinology*, ed 13, Philadelphia, 2016, Elsevier. Table 8.5, p. 193, in Kliegman RM: *Nelson Textbook of Pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

Rx TREATMENT

Threefold: Removing underlying cause (surgery or radiation), treating hormonal deficiencies, and addressing any other repercussions from deficiency. Table 3 summarizes replacement therapy for adult hypopituitarism.

NONPHARMACOLOGIC THERAPY

- IV fluid resuscitation, correction of electrolyte and metabolic abnormalities with potassium bicarbonate, and oxygen therapy.
- Transsphenoidal surgery for tumors causing specific symptoms.
- Radiation or stereotactic radiosurgery ("gamma knife") for medically unresponsive, surgically unresectable tumors and tumors for which other modalities are contraindicated. It is both safe and effective for recurrent or residual pituitary adenomas.

ACUTE GENERAL Rx

Acute situations such as adrenal crisis or myxedema coma can occur in untreated hypopituitarism and should be treated accordingly with IV corticosteroids (e.g., hydrocortisone 100 to 250 mg bolus followed by hydrocortisone 100 mg IV q6h for 24 hr) and levothyroxine (e.g., 5 to 8 mcg/kg IV over 15 min, then 100 mcg IV q24h).

CHRONIC Rx

Treatment is lifelong:
- Adrenocorticotropic hormone (ACTH) deficiency: Hydrocortisone 10 mg PO every morning and 5 mg PO every evening or prednisone 5 mg PO every morning and 2.5 mg PO every evening. Dexamethasone or prednisone is often preferred because of longer duration of action.
- LH and FSH deficiency:
  1. In men, testosterone enanthate or propionate 200 to 300 mg IM every 2 to 3 wk, or transdermal testosterone scrotal patches can be tried.
  2. In women who are not interested in fertility, conjugated estrogen 0.3 to 1.25 mg/day and held the last 5 to 7 days of each mo with the addition of medroxyprogesterone 10 mg/day given during days 15 to 25 of the normal menstrual cycle. In those who have secondary hypogonadism and wish to become pregnant, pulsatile gonadotropic-releasing hormone may be of benefit.
- TSH deficiency: Levothyroxine 0.05 to 0.2 mg/day. Only free thyroxine should be used to monitor appropriate dosing to maintain thyroxine level in the mid to upper half of normal range.
- GH deficiency:
  1. GH replacement in children is universally accepted.
  2. GH replacement in adults is not generally recommended and requires careful consideration of each individual case. It may have effects on quality of life, body composition, bone density, and cardiovascular risk factors.
  3. Side effects of replacement include peripheral edema, arthralgia, and headaches.
  4. Usual GH dose is between 0.2 and 0.4 mg, determined by the age and gender of a patient and increments of 0.1 mg every 2 to 4 wk until serum IGF-1 is in the upper part of the normal range. Young adults and women taking estrogen require a higher dose.
- ADH deficiency:
  1. Desmopressin (DDAVP) 10 to 20 mcg by intranasal spray or 0.05 to 0.1 mg PO bid is used in patients with diabetes insipidus.
  2. Vasopressin: 5 to 10 U given IM or SC q6h.

DISPOSITION

- Hormone replacement therapy is adjusted according to serum hormone monitoring.
- If untreated can lead to adrenal crisis, severe hyponatremia and hypothyroidism, metabolic abnormalities, and death.
- Complications: Visual deficit, adrenal crisis, susceptibility to infection and other stressors.
- Prognosis: Stable patients have a favorable prognosis with replacement hormone therapy. Patients with acute decompensation are in critical condition with a high mortality rate.

REFERRAL

Consultation with an endocrinologist and neurosurgeon for surgical treatment

PEARLS & CONSIDERATIONS

- All patients sustaining moderate to severe head injury should undergo assessment of anterior pituitary function during the acute phase and at 6 mo.
- IGF-1 can be used as a marker of GH deficiency.
- All tests of GH secretion are more likely to give false-positive results in obese patients.
- The GH axis is the most vulnerable to the effects of radiotherapy; doses as low as 18 Gy in children have caused GH deficiency.
- Sequence of hormonal disruption: GH secretion then gonadotropin secretion. TSH and adrenocorticotropic hormone secretion are somewhat resistant.
- Thyroxine supplementation increases the rate of cortisol metabolism and can lead to adrenal crisis, so corticosteroids should be replaced first.
- All patients receiving glucocorticoid replacement therapy should wear proper identification stating the need for this therapy.

TABLE 2 Assessment of Anterior Pituitary Function

Test	Dose	Normal Response	Side Effects
ACTH			
Insulin tolerance	0.1-0.15 U/kg IV	Peak cortisol response >18 μg/dl, or ≥5 μg/dl	Sweating, palpitation, tremor
Metyrapone	30 mg/kg PO at 11 P.M.	Peak 11-DOC ≥7 μg/dl Peak cortisol ≤7 μg/dl Peak ACTH >75 pg/ml	Nausea, insomnia, adrenal crisis
CRH stimulation	100 μg IV	Peak ACTH ≥2-4-fold Peak cortisol ≥20 μg/dl or ↑ ≥7 μg/dl	Flushing
ACTH stimulation	250 μg IV or IM, or 1 μg IV	Peak cortisol ≥20 μg/dl	Rare
TSH			
Serum T_4 (free T_4) Total T_3 TSH—third-generation TRH stimulation	200-500 μg IV	Peak TSH ≥2.5-fold, or ↑ ≥5-6 mU/L (females) or ≥2-3 mU/L (males)	Flushing, nausea, urge to micturate
PRL			
Serum PRL TRH stimulation	200-500 μg IV	PRL ↑ ≥2.5-fold	Flushing, nausea, urge to micturate
LH/FSH			
Serum LH and FSH Serum testosterone GnRH stimulation	100 μg IV	Elevated in menopause and in men with primary testicular failure (otherwise normal) 300-900 ng/ml LH ≥2-3-fold, or ↑ by 10 IU/L FSH ≥1.5-2-fold, or ↑ ≥2 IU/L	Rare
GH			
Insulin tolerance	0.1-0.15 U/kg	GH peak >5 μg/L	Sweating, palpitation, tremor
L-Arginine	Arginine 0.5 g/kg (maximum, 30 g) IV over 30-120 min	GH peak >0.4 μg/L	Nausea
Plus			
GHRH	GHRH 1-5 μg/kg	GH peak >4 μg/L	Flushing

ACTH, Adrenocorticotropic hormone; *CRH,* corticotropin-releasing hormone; *11-DOC,* 11-deoxycorticosterone; *FSH,* follicle-stimulating hormone; *GH,* growth hormone; *GHRH,* growth hormone–releasing hormone; *GnRH,* gonadotropin-releasing hormone; *IM,* intramuscular; *IV,* intravenous; *LH,* luteinizing hormone; *PO,* by mouth; *PRL,* prolactin; T_3, triiodothyronine; T_4, thyroxine; *TRH,* thyrotropin-releasing hormone; *TSH,* thyroid-stimulating hormone; *TRH,* thyrotropin-releasing hormone.

TABLE 3 Replacement Therapy for Adult Hypopituitarism*

Deficient Hormone

Treatment

ACTH

Hydrocortisone: 10-20 mg/day in divided doses
Cortisone acetate: 15-25 mg/day in divided doses

TSH

L-Thyroxine: 0.05-0.2 mg/day according to T_4 levels

FSH/LH (in males)

Testosterone enanthate: 200 mg IM q2-3 wk
Testosterone skin patch: 2.5-5.0 mg/day (or up to 7.5 mg/day)
Testosterone gel: 3-6 g/day

For fertility: hCG three times weekly, or hCG + either FSH or menopausal gonadotropin or GnRH

FSH/LH (in females)

Conjugated estrogen: 0.3-0.625 mg/day
Micronized estradiol: 1 mg/day
Estradiol valerate: 2 mg
Piperazine estrone sulfate: 1.25 mg
Estradiol skin patch: 4-8 mg twice weekly

All of the estrogens are administered with progesterone or progestin sequentially or in combination if uterus is present
For fertility: Menopausal gonadotropin, and hCG, or GnRH

Growth hormone

Somatotropin (in adults): 0.2-1.0 mg/day SC
Somatotropin (in children): 0.02-0.05 mg/kg per day

Vasopressin

Intranasal desmopressin: 10-20 μg bid
Oral DDAVP: 300-600 μg/day, usually in divided doses

ACTH, Adrenocorticotropic hormone; *bid,* twice per day; *DDAVP,* desmopressin acetate; *FSH,* follicle-stimulating hormone; *GnRH,* gonadotropin-releasing hormone; *hCG,* human chorionic gonadotropin; *IM,* intramuscular; *LH,* luteinizing hormone; *SC,* subcutaneous; T_4, thyroxine; *TSH,* thyroid-stimulating hormone.
From Melmed S, Polonsky KS, Larsen PR, Kronenberg HM: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, WB Saunders, Elsevier Inc.

- Stress doses of corticosteroids are indicated before surgery or for any medical emergency (e.g., sepsis, acute myocardial infarction).
- Antidiuretic hormone deficiency may be masked if there is ACTH deficiency with symptoms only appearing when cortisol has been replaced.

COMMENTS

- Mineralocorticoid replacement is not necessary in secondary adrenal insufficiency because the renin-angiotensin-aldosterone system is unaffected by pituitary failure.
- Patients with adult-acquired GH deficiency must meet at least two criteria before replacement therapy: A poor GH response to at least two standard stimuli and hypopituitarism from pituitary or hypothalamic damage. The criteria are different in children in whom GH is required for normal growth.
- Prevention of acute decompensation can be accomplished by reminding patients to increase the dose of hydrocortisone in response to stress.
- Medical therapy should precede surgical therapy.

BASIC INFORMATION

DEFINITION

Hypospadias is a developmental abnormality of the penis characterized by:

- Abnormal ventral opening of the urethral meatus anywhere from the ventral aspect of the glans penis to the perineum
- Ventral curvature of the penis (chordee)
- Dorsal foreskin hood

ICD-10CM CODES

Q54.1 Hypospadias, penile
Q54.2 Hypospadias, penoscrotal
Q54.3 Hypospadias, perineal
Q54.4 Congenital chordee
Q54.8 Other hypospadias
Q54.9 Hypospadias, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- One of the most common congenital anomalies in males
- Prevalence is highest in North America at 34.2 per 10,000 births, and lowest in Asia at 0.6 per 10,000 births

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Genetics: Normal karyotypes are seen with glanular hypospadias; abnormal karyotypes are noted in more severe forms of hypospadias
- Cryptorchidism: 8% to 9% occurrence
- Inguinal hernia: 9% to 10% occurrence
- Hydrocele: 9% to 16% occurrence

PENILE CURVATURE (CHORDEE): Three theories:

- Abnormal development of the urethral plate
- Abnormal fibrotic mesenchymal tissue at the urethral meatus
- Corporal disproportion

ETIOLOGY

Multifactorial:

- Genetic predisposition:
  1. There is a 9% to 17% recurrence rate in male siblings and an 8% recurrence rate in male offspring of men who have hypospadias.
  2. Only 30% of hypospadias cases have a clear genetic cause.
  3. The condition has an estimated 57% to 77% heritability and is equally transmitted through maternal and paternal sides of the family.
- Maternal and other influences:
  1. There is increased incidence in small for gestational age infants and monochorionic twins.
  2. Severe hypospadias is seen in patients with maternal hypertension, oligohydramnios, and preterm delivery, suggesting placental insufficiency may play a role.
  3. Males conceived by in vitro fertilization (IVF)/intracytoplasmic sperm injection (ICSI) may have a fivefold increased risk of hypospadias, according to some studies.
- Hormonal factors:
  1. Disruption in prenatal androgen exposure
  2. Fetal exposure to maternal estrogenic compounds (progestin or diethylstilbestrol)
  3. Possible link to disturbed testicular development as seen in testicular dysgenesis syndrome

DIAGNOSIS

WORKUP

Made by observation and examination (Fig. E1)

LABORATORY TESTS

The clinician always should consider a disorder of sex development (DSD) if there is associated cryptorchidism. The evaluation should include ultrasound; genitographic studies; and chromosomal, gonadal, biochemical, and molecular studies.

TREATMENT

ACUTE GENERAL Rx

CLASSIFICATION BASED ON MEATAL POSITION:

- Distal (glandular, coronal, subcoronal): 60%
- Middle (distal shaft, midshaft, posterior penile): 25%
- Proximal (penoscrotal, scrotal, perineal): 15%

SPECIAL CONSIDERATIONS:

- The major reason for operating on any patient with hypospadias is to correct deformities that interfere with the function of urination and procreation.
- Another reason for intervention is cosmetic concern.
- The American Academy of Pediatrics recommends the best time for surgical intervention to be 6 to 12 mo.

HORMONAL MANIPULATION:

- Controversial.
- Human chorionic gonadotropin (hCG) administration is given before repair of proximal hypospadias.
- The effect of hCG administration is decreased hypospadias and chordee severity in all patients and increased vascularity and thickness of the proximal corpus spongiosum.
- Application of topical testosterone increases mean penile circumference and length without any lasting side effects.
- Prepubertal exogenous testosterone does not adversely affect ultimate penile growth.

CHRONIC Rx

Surgical procedures:

- Orthoplasty (correcting penile curvature)
- Urethroplasty
- Meatoplasty
- Glanuloplasty
- Skin coverage

There is no single universally acceptable applicable technique for hypospadias repair.

Complications may occur up to 5 yr after the procedure, and therefore the patients should be monitored beyond the first yr, particularly in cases of middle or proximal hypospadias.

TYPES OF REPAIR

- Urethral plate tubularization: Makes a new urethra by rolling a ventral strip of skin from the penile shaft in glandular and penile shaft repairs
- Urethral plate augmentation: Used for more severe hypospadias where a urethra is created using a vascular strip of inner foreskin that is transferred to the ventral skin
- Urethral plate substitution (two stage repair): Used in the most extreme/severe cases
  1. Stage one: Corrects the penile curvature and transfers dorsal foreskin to the ventral side of the penis
  2. Stage two: Urethroplasty that occurs 6 mo after the first operation

COMPLICATIONS OF REPAIR: Hematoma, meatal stenosis, fistula, urethral stricture, urethral diverticulum, wound infection, impaired healing, balanitis xerotica obliterans, penile curvature

PEARLS & CONSIDERATIONS

- Apparent simple isolated hypospadias may be the only visible indication of an underlying abnormality.
- The dorsal hood of redundant foreskin is used in the repair of hypospadias, so the patient with hypospadias and a dorsal hood should not be circumcised.

BASIC INFORMATION

DEFINITION

Hypothermia is a rectal temperature <35° C (95.8° F). "Accidental hypothermia" is an unintentionally induced decrease in core temperature in the absence of preoptic anterior hypothalamic conditions.

ICD-10CM CODES

R68.0	Hypothermia, not associated with low environmental temperature
T68	Hypothermia

EPIDEMIOLOGY & DEMOGRAPHICS

- Hypothermia occurs most frequently in the following groups: Alcoholics; homeless; learning-impaired; patients with cardiovascular, cerebrovascular, or pituitary disorders; those using sedatives or tranquilizers; and elderly patients.
- >700 persons in the U.S. die from hypothermia annually.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The clinical presentation varies with the severity of hypothermia. Shivering may be absent if body temperature is <33.3° C (92° F) or in patients taking phenothiazines.

Hypothermia may masquerade as cerebrovascular accident, ataxia, or slurred speech, or the patient may appear comatose or clinically dead. Signs of hypothermia are summarized in Box E1. Physiologic stages of hypothermia:

- Stage HT I: Mild hypothermia (typical core temperature 32.2° C to 35 °C [90° F to 95° F]): Arrhythmias, ataxia
- Stage HT II: Moderate hypothermia (core temperature 28° C to 32.2° C [82.4° F to 90° F]):
  1. Progressive decrease of level of consciousness, pulse, cardiac output, and respiration
  2. Fibrillation, dysrhythmias (increased susceptibility to ventricular tachycardia)
  3. Elimination of shivering mechanism for thermogenesis
- Stage HT III: Severe hypothermia (core temperature ≤28° C to 24° C [82.4° F to 75° F]):
  1. Absence of reflexes or response to pain
  2. Decreased cerebral blood flow, decreased CO_2
  3. Increased risk of ventricular fibrillation or asystole
  4. Vital signs present
- Stage IV: No vital signs (core temperature <24° C [75° F])

ETIOLOGY

Exposure to cold temperatures for a prolonged period. Contributing factors include:

- Drugs: Ethanol, phenothiazines, sedative-hypnotics
- Skin disorders: Extensive burns, severe psoriasis, exfoliative dermatitis
- Metabolic disorders: Hypopituitarism, hypothyroidism, hypoadrenalism
- Neurologic abnormalities: Stroke, head trauma, acute spinal cord transection, impaired shivering
- Other: Lack of acclimatization, aggressive fluid resuscitation, sepsis, heat stroke treatment
- Box E2 summarizes factors predisposing to hypothermia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- It is crucial to determine an accurate core temperature measurement. Advantages and considerations of various methods to determine core temperature are summarized in Table 1. Core temperature is best monitored with an esophageal probe. Rectal and bladder temperature generally lag behind core temperatures during the rewarming process
- Cerebrovascular accident
- Myxedema coma
- Drug intoxication
- Hypoglycemia

LABORATORY TESTS

- Metabolic and respiratory acidosis are usually present.
  1. When blood cools, the arterial pH increases, oxygen tension (Po_2) increases, and the pCO_2 falls. Temperature correction factors for arterial blood gas specimens are summarized in Box 3.
  2. Blood gas analyzers warm the blood to 37° C (98.6° F), increasing the partial pressure of dissolved gases, resulting in higher oxygen and carbon dioxide levels and a lower pH than the patient's actual values. A decrease in K^+ initially, then an increase in K^+ with increasing hypothermia; extreme hyperkalemia indicates a poor prognosis.
- Hematocrit increases (caused by hemoconcentration), decreasing leukocytes and platelets (caused by splenic sequestration).
- Blood viscosity, increased clotting time.

IMAGING STUDIES

- Chest x-ray: Generally not helpful; may reveal evidence of aspiration (e.g., intoxicated patient with aspiration pneumonia).

TABLE 1 Core Temperature Measurements

Type	Advantages	Considerations
Rectal	Convenient	Insert 15 cm (6 inches)
	Continuous monitoring	Lags during transition from cooling to rewarming
		Falsely elevated with peritoneal lavage
		Falsely low if probe is in cold feces or when lower extremities are frozen
Esophageal	Convenient	Insert 24 cm (9.5 inches) below larynx
	Continuous monitoring	Tracheal misplacement
		Aspiration
		Falsely elevated with heated inhalation
Tympanic	Approximates hypothalamic temperature via internal carotid artery	Probe: Tympanic membrane perforation; canal hemorrhage Infrared: Unreliable; cerumen effect
Bladder	Convenient	Unreliable
	Continuous monitoring	Falsely elevated with peritoneal lavage
		Falsely low with cold diuresis

BOX 3 Temperature Correction Factors for Arterial Blood Gas Specimens*

ABG Component Correction Factor

$pH + 0.015 (37 - T_c)$

$Pa_{O_2} - 0.072 (37 - T_c) \times Pa_{O_2}$

$Pa_{CO_2} - 0.044 (37 - T_c) \times Pa_{CO_2}$

Example

A patient presents with a core temperature of 32° C with the following ABG values: pH 7.12, Pa_{CO_2} 52 mm Hg, and Pa_{O_2} 52 mm Hg. Corrections for temperature are as follows:

$pH = 7.12 + [0.015 (37 - 32)] = 7.195$

$Pa_{O_2} = 52 - [0.072 (37 - 32) \times 52] = 33.28$ mm Hg

$Pa_{CO_2} = 52 - [0.044 (37 - 32) \times 52] = 40.56$ mm Hg

These corrections also may be used for hyperthermia.

*Arterial blood gas values not corrected for temperature in significantly hypothermic patients yield falsely low pH and falsely elevated Pa_{CO_2} and Pa_{O_2} values.

ABG, Arterial blood gas; Pa_{O_2}, partial pressure of oxygen; Pa_{CO_2}, partial pressure of arterial carbon dioxide; T_c, core temperature.

From Parrillo JE, Dellinger RP: *Critical care medicine, principles of diagnosis and management in the adult,* ed 5, Philadelphia, 2019, Elsevier.

FIG. 1 Hypothermic J waves (Osborne waves) *(arrows)* in an 80-yr-old man with core temperature of 86° F (30° C). These waves disappeared with rewarming.

BOX 4 Preparing Hypothermic Patients for Transport

1. The patient must be dry. Gently remove or cut off wet clothing and replace it with dry clothing or a dry insulation system. Keep the patient horizontal, and do not allow exertion or massage of the extremities.
2. Stabilize injuries (i.e., the spine; place fractures in the correct anatomic position). Open wounds should be covered before packaging.
3. Initiate heated intravenous infusions (IVs) if feasible; bags can be placed under the patient's buttocks or in a compressor system. Administer a fluid challenge.
4. Active rewarming should be limited to heated inhalation and truncal heat. Insulate hot water bottles in stockings or mittens, and then place them in the patient's axillae and groin.
5. The patient should be wrapped. Begin building the wrap by placing a large plastic sheet on the available surface (floor, ground), and on it place an insulated sleeping pad. A layer of blankets, a sleeping bag, or bubble wrap insulating material is laid over the sleeping pad. The patient is then placed on the insulation. Heating bottles are put in place along with IVs, and the entire package is wrapped layer over layer, with the plastic as the final closure. The patient's face should be partially covered, but a tunnel should be created to allow access for breathing and monitoring.

From Auerbach P: *Wilderness medicine, expert consult premium edition—enhanced online features and print,* Philadelphia, 2012, Elsevier.

- ECG: Prolonged PR, QT, and QRS segments, depressed ST segments, inverted T waves, atrioventricular block, and hypothermic J waves (Osborne waves) may appear at temperatures less than 33.0° C (91.4° F); characterized by notching of the junction of the QRS complex and ST segments (Fig. 1).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- The first critical step in management of accidental hypothermia is initiating passive external rewarming by removing wet clothing and covering the patient with insulating material.
- Specific treatment of hypothermia varies with the following:
  1. Degree of hypothermia.
  2. Existence of concomitant diseases (e.g., cardiovascular insufficiency).
  3. Patient's age and medical condition (e.g., elderly, debilitated patients vs. young, healthy patients).
- General measures:
  1. Secure an airway before warming all unconscious patients; precede endotracheal intubation with oxygenation (if possible) to minimize the risk of arrhythmias during the procedure.
  2. Peripheral vasoconstriction may impede placement of a peripheral intravenous catheter; consider femoral venous access as an alternative to the jugular or subclavian sites to avoid ventricular stimulation.
  3 A Foley catheter should be inserted, and urinary output should be monitored and maintained >0.5 to 1 ml/kg/hr with intravascular volume replacement.
  4. Box 4 summarizes measures for preparing hypothermic patients for transport.

ACUTE GENERAL Rx

- Continuous ECG monitoring of patients is recommended. Ventricular arrhythmias can be treated with bretylium; lidocaine is generally ineffective, and procainamide is associated with an increased incidence of ventricular fibrillation in hypothermic patients.
- Correct severe acidosis and electrolyte abnormalities.
- Hypothyroidism, if present, should be promptly treated (see "Myxedema Coma").
- If clinical evidence suggests adrenal insufficiency, administer IV methylprednisolone.

In patients unresponsive to verbal or noxious stimuli or with altered mental status, 100 mg of thiamine, 0.4 mg of naloxone, and 1 ampule of 50% dextrose may be given.

Warm (104° F to 113° F [40° C to 45° C]), humidified oxygen should also be given if available.

- Specific treatment:
  1. Mild hypothermia (rectal temperature <32.3° C [90° F]): Passive external rewarming is indicated. Place the patient in a warm room (temperature >21° C [69.8° F]), and cover with insulating material after gently removing wet clothing; recommended rewarming rates vary between 0.5° C/hr and 20° C/hr (32.9° F/hr and 68° F/hr) but should not exceed 0.55° C/hr (32.99° F/hr) in elderly persons
  2. Moderate to severe hypothermia:
     a. Active core rewarming
        (1) Delivery of heat by way of fluids: Warm gastrointestinal irrigation (with saline enemas and by nasogastric tube); IV fluids (usually D_5NS without potassium) warmed to 104° F to 107.6° F (40° C to 42° C), peritoneal dialysis with dialysate heated to 40.5° C to 42.5° C (104.9° F/hr to 108.5° F/hr)
        (2) Inhalation of heated, humidified oxygen (warmed to 40° C [104° F]) increases core temperature by 1° C (1.8° F) per hr and decreases evaporative heat loss from respiration
  3. Active external rewarming: Immersion in a bath of warm water (40° C to 41° C); active external rewarming may produce shock because of excessive peripheral vasodilation. Ideal candidates are previously healthy, young patients with acute immersion hypothermia.
  4. Extracorporeal blood warming with cardiopulmonary bypass appears to be an efficacious rewarming technique in young, otherwise healthy persons.
  5. Patients with cardiac instability and those in cardiac arrest should be transported to a center capable of providing extracorporeal membrane oxygenation (ECMO) unless other conditions (e.g., trauma) require transport to a closer facility.

SUGGESTED READING

Brown DJA et al: Accidental hypothermia, *N Engl J Med* 367:1830-1838, 2012.

BOX E1 Signs of Hypothermia

Head, Eye, Ear, Nose, Throat
- Mydriasis
- Decreased corneal reflexes
- Extraocular muscle abnormalities
- Erythropsia
- Flushing
- Facial edema
- Epistaxis
- Rhinorrhea
- Strabismus

Cardiovascular
- Initial tachycardia
- Subsequent tachycardia
- Arrhythmias
- Decreased heart tones
- Hepatojugular reflux
- Jugular venous distention
- Hypotension
- Peripheral vasoconstriction

Respiratory
- Initial tachypnea
- Adventitious sounds
- Bronchorrhea
- Progressive hypoventilation
- Apnea

Gastrointestinal
- Ileus
- Constipation
- Abdominal distention or rigidity
- Poor rectal tone
- Gastric dilation in neonates or in adults with myxedema
- Vomiting

Genitourinary
- Anuria
- Polyuria
- Oliguria
- Testicular torsion

Neurologic
- Depressed level of consciousness
- Ataxia
- Dysarthria
- Amnesia
- Anesthesia
- Areflexia
- Poor suck reflex
- Hypoesthesia
- Antinociception
- Initial hyperreflexia
- Hyporeflexia
- Central pontine myelinolysis

Psychiatric
- Impaired judgment
- Perseveration
- Mood changes
- Peculiar "flat" affect
- Altered mental status
- Paradoxical undressing
- Neuroses
- Psychoses
- Suicide
- Organic brain syndrome
- Anorexia nervosa
- Depression
- Apathy
- Irritability

Musculoskeletal
- Increased muscle tone
- Shivering
- Rigidity or pseudo-rigor mortis
- Paravertebral spasm
- Opisthotonos
- Compartment syndrome

Dermatologic
- Erythema
- Pallor
- Cyanosis
- Icterus
- Scleral edema
- Ecchymosis
- Edema
- Pernio
- Frostnip
- Frostbite
- Panniculitis
- Cold urticaria
- Necrosis
- Gangrene

BOX E2 Factors Predisposing to Hypothermia

Decreased Heat Production
Endocrinologic Failure
- Hypopituitarism
- Hypoadrenalism
- Hypothyroidism
- Lactic acidosis
- Diabetic and alcoholic ketoacidosis

Insufficient Fuel
- Hypoglycemia
- Malnutrition
- Marasmus
- Kwashiorkor
- Extreme physical exertion

Neuromuscular Physical Exertion
- Age extremes
- Impaired shivering
- Inactivity
- Lack of adaptation

Impaired Thermoregulation
Peripheral Failure
- Neuropathies
- Acute spinal cord transection
- Diabetes

Central or Neurologic Failure
- Cardiovascular accident
- Central nervous system trauma
- Toxicologic effects
- Metabolic failure
- Subarachnoid hemorrhage
- Pharmacologic effects
- Hypothalamic dysfunction
- Parkinson disease
- Anorexia nervosa
- Cerebellar lesion
- Neoplasm
- Congenital intracranial anomalies
- Multiple sclerosis
- Hyperkalemic periodic paralysis

Increased Heat Loss
Environmental
- Immersion
- Nonimmersion

Induced Vasodilation
- Pharmacologic effects
- Toxicologic effects

Erythrodermas
- Burns
- Psoriasis
- Ichthyosis
- Exfoliative dermatitis

Iatrogenic
- Emergency childbirth
- Cold infusions
- Heatstroke treatment

Miscellaneous Associated Clinical States
- Multisystem trauma
- Recurrent hypothermia
- Episodic hypothermia
- Shapiro syndrome
- Infections: Bacterial, viral, parasitic
- Pancreatitis
- Carcinomatosis
- Cardiopulmonary disease
- Vascular insufficiency
- Uremia
- Paget disease
- Giant cell arteritis
- Sarcoidosis
- Shaken baby syndrome
- Systemic lupus erythematosus
- Wernicke-Korsakoff syndrome
- Hodgkin disease
- Shock
- Sickle cell anemia
- Sudden infant death syndrome

BASIC INFORMATION

DEFINITION

Hypothyroidism is a disorder caused by the inadequate secretion of thyroid hormone.

SYNONYM

Myxedema

ICD-10CM CODES

E00.9	Congenital iodine-deficiency syndrome, unspecified
E02	Subclinical iodine-deficiency hypothyroidism
E03.0	Congenital hypothyroidism with diffuse goiter
E03.1	Congenital hypothyroidism without goiter
E03.2	Hypothyroidism due to medicaments and other exogenous substances
E03.3	Postinfectious hypothyroidism
E03.8	Other specified hypothyroidism
E03.9	Hypothyroidism, unspecified
E89.0	Postprocedural hypothyroidism

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE & PREVALENCE: 1.5% to 2% of women and 0.2% of men. Overall, about 1 in 300 persons in the U.S. has hypothyroidism.

PREDOMINANT AGE: Incidence of hypothyroidism increases with age; among persons older than 60 yr, 6% of women and 2.5% of men have laboratory evidence of hypothyroidism (thyroid-stimulating hormone [TSH] more than twice normal level).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Hypothyroid patients generally present with the following signs and symptoms: Fatigue, lethargy, weakness, constipation, weight gain, cold intolerance, muscle weakness, slow speech, slow cerebration with poor memory
- Skin: Dry, coarse, thick, cool, sallow (yellow color caused by carotenemia); nonpitting edema in skin of eyelids and hands (myxedema) secondary to infiltration of subcutaneous tissues by a hydrophilic mucopolysaccharide substance (Fig. E1, *A* and *B*)
- Hair: Brittle and coarse; loss of outer third of eyebrows
- Faces: Dulled expression, thickened tongue, thick and slow-moving lips
- Thyroid gland: May or may not be palpable (depending on the cause of the hypothyroidism)
- Heart sounds: Distant, possible pericardial effusion
- Pulse: Bradycardia
- Neurologic: Delayed relaxation phase of the deep tendon reflexes, cerebellar ataxia, hearing impairment, poor memory, peripheral neuropathies with paresthesia
- Musculoskeletal: Carpal tunnel syndrome, muscular stiffness, weakness

ETIOLOGY

- Primary hypothyroidism (thyroid gland dysfunction): The cause of >90% of the cases of hypothyroidism
  1. Hashimoto thyroiditis is the most common cause of hypothyroidism after age 8 yr
  2. Idiopathic myxedema (nongoitrous form of Hashimoto thyroiditis)
  3. Previous treatment of hyperthyroidism (radioiodine therapy, subtotal thyroidectomy)
  4. Subacute thyroiditis
  5. Radiation therapy to the neck (usually for malignant disease)
  6. Iodine deficiency or excess
  7. Drugs (lithium, para-aminosalicylate, sulfonamides, phenylbutazone, amiodarone, thiourea)
  8. Congenital (approximately one case per 2000 to 4000 live births)
  9. Prolonged treatment with iodides
- Secondary hypothyroidism: Pituitary dysfunction, postpartum necrosis, neoplasm, infiltrative disease-causing deficiency of TSH
- Tertiary hypothyroidism: Hypothalamic disease (granuloma, neoplasm, or irradiation causing deficiency of thyrotropin-releasing hormone)
- Tissue resistance to thyroid hormone: Rare

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Depression
- Dementia from other causes
- Systemic disorders (e.g., nephrotic syndrome, congestive heart failure, amyloidosis)

LABORATORY TESTS

- TSH, free T4, thyroid peroxidase antibodies (TPOAB).
- Increased TSH: TSH may be normal if patient has secondary or tertiary hypothyroidism, is receiving dopamine or corticosteroids, or the level is obtained after severe illness.
- Decreased free T4 in hypothyroidism, normal free T4 in subclinical hypothyroidism.
- Other common laboratory abnormalities: Hyperlipidemia, hyponatremia, and anemia.
- Increased antimicrosomal and antithyroglobulin antibody titers: Useful when autoimmune thyroiditis is suspected as the cause of the hypothyroidism. The American Thyroid Association recommends treatment of pregnant patients with subclinical hypothyroidism and anti-thyroid peroxidase (anti-TPO) antibody positivity.
- Fig. 2 describes a strategy for the laboratory evaluation of patients with suspected hypothyroidism.

TREATMENT

NONPHARMACOLOGIC THERAPY

Patients should be educated regarding hypothyroidism and its possible complications. Patients should also be instructed about the need for lifelong treatment and monitoring of their thyroid abnormality.

ACUTE GENERAL Rx

Start replacement therapy with levothyroxine (L-thyroxine) 25 to 100 μg/day, depending on the patient's age and the severity of the disease. Physiologic combinations of L-thyroxine plus liothyronine do not offer any objective advantage over L-thyroxine alone. The levothyroxine dose may be increased every 6 to 8 wk, depending on the clinical response and serum TSH level. Elderly patients and patients with coronary artery disease should be started with 12.5 to 25 μg/day (higher doses may precipitate angina). The average maintenance dose of levothyroxine is 1.7 μg/kg/day (100 to 150 μg/day in adults). The elderly may require <1 μg/kg/day, whereas children generally require higher doses (up to 3 to 4 μg/kg/day). Pregnant patients also have increased requirements. Estrogen therapy may also increase the need for thyroxine. Women with hypothyroidism should increase their levothyroxine dose by approximately 30% as soon as pregnancy is confirmed. Close monitoring of serum thyrotropin levels and adjustment of levothyroxine dose to maintain a TSH level of 4.0 mU/L as upper limit is recommended throughout pregnancy. Table 1 summarizes conditions that alter levothyroxine requirements.

CHRONIC Rx

- Periodic monitoring of TSH level is an essential part of treatment. Patients should be evaluated initially with office visit and TSH levels every 6 to 8 wk until the patient is clinically euthyroid and the TSH level is normalized. The frequency of subsequent visits and TSH measurement can then be decreased to every 6 to 12 mo. Pregnant patients should be checked every trimester.
- For monitoring therapy in patients with central hypothyroidism, measurement of serum free thyroxine (free T4 level) is appropriate and should be maintained in the upper half of the normal range.

REFERRAL

Admission to the hospital intensive care unit is recommended in all patients with myxedema coma. Additional information on the diagnosis and treatment of this life-threatening complication of hypothyroidism is available under "Myxedema Coma" in Section I.

PEARLS & CONSIDERATIONS

COMMENTS

Subclinical hypothyroidism occurs in as many as 20% of elderly patients and is characterized by an elevated serum TSH and a normal free T_4 level. Subclinical hypothyroidism can progress to overt hypothyroidism, especially if antithyroid antibodies are present. It is associated with an increased risk of coronary heart disease events and mortality, particularly in those with a TSH concentration of 10 mU/L or greater. Treatment is individualized and controversial.

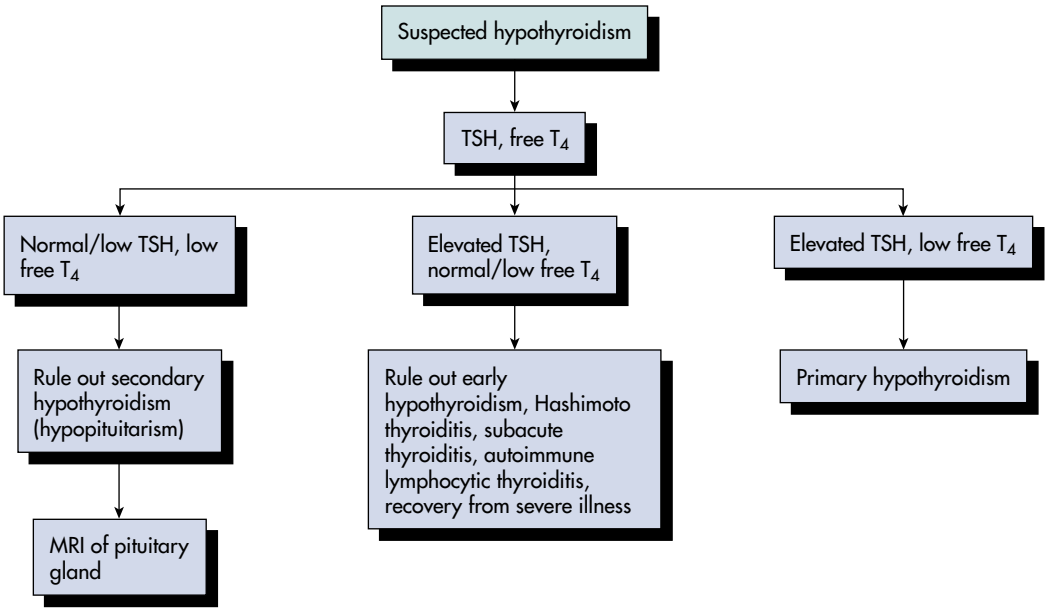

FIG. 2 Strategy for the laboratory evaluation of patients with suspected hypothyroidism. The principal differential diagnosis is between primary and central hypothyroidism. The serum thyrotropin *(TSH)* concentration is the critical laboratory determination that, in general, allows recognition of the cause of the disease. An exception is the individual with a recent history of thyrotoxicosis (and suppressed TSH), in whom a low free thyroxine (T_4) level may be associated with a reduced TSH level for several mo after relief of the thyrotoxicosis. In patients with primary hypothyroidism, the absence of thyroid peroxidase (TPO) antibodies raises a possible diagnosis of transient hypothyroidism after an undiagnosed episode of subacute or postviral thyroiditis. In such patients, a trial of levothyroxine in reduced dosage after 4 mo may reveal recovery of thyroid function, thus avoiding permanent levothyroxine replacement. *MRI,* Magnetic resonance imaging. (From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, WB Saunders.)

TABLE 1 Conditions That Alter Levothyroxine Requirements

Increased Levothyroxine Requirements
Pregnancy
Gastrointestinal Disorders
Mucosal diseases of the small bowel (e.g., sprue)
After jejunoileal bypass and small-bowel resection
Impaired gastric acid secretion (e.g., atrophic gastritis)
Diabetic diarrhea
Drugs That Interfere with Levothyroxine Absorption
Cholestyramine
Sucralfate
Aluminum hydroxide
Calcium carbonate
Ferrous sulfate
Drugs That Increase the Cytochrome P450 Enzyme (CYP3A4) Activity
Rifampin
Carbamazepine
Estrogen
Phenytoin
Sertraline
Drugs That Block T_4-to-T_3 Conversion
Amiodarone
Conditions That May Block Deiodinase Synthesis
Selenium deficiency
Cirrhosis
Decreased Levothyroxine Requirements
Aging (≥65 yr)
Androgen therapy in women

T_3, Triiodothyronine; *T_4,* thyroxine.
(From Melmed S et al: *Williams textbook of endocrinology,* ed 12, Philadelphia, 2011, WB Saunders.)

Some trials[1] have shown that levothyroxine provides no apparent benefit in older persons with subclinical hypothyroidism. The management of subclinical hypothyroidism should be individualized on the basis of TSH level, comorbid conditions, risk factors, and patient preference. In general, replacement therapy is recommended by most physicians for patients with serum TSH >10 mU/L and with presence of goiter or thyroid autoantibodies or patient has risk factors.

Congenital hypothyroidism is a pediatric disorder with an observed prevalence of one in 2000 to 4000 live births in the U.S. Screening is conducted in all newborns in all states and accomplished by measuring TSH from dried whole blood spots collected on a newborn by heel stick within the first 24 to 48 hours of life. Currently 14 states perform a routine second screen at approximately 2 wk of age. A two-screen approach is preferred because retrospective analysis found that 20% of congenital hypothyroidism cases were in infants who had normal TSH on the first screen but elevated TSH concentrations on the second screen.

ID Reaction

BASIC INFORMATION

DEFINITION

ID reaction refers to an acute dermatitis developing at cutaneous sites distant from a primary inflammatory focus (Fig. E1) and is not explained by the inciting primary inflammation.

SYNONYM

Autoeczematization

ICD-10CM CODES

L30.2	Cutaneous autosensitization
L30.8	Other specified dermatitis
L30.9	Dermatitis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- Exact prevalence in the U.S. is unknown.
- Seen in all ages.
- Males and females are equally affected.
- No particular race or ethnicity is more vulnerable.

ETIOLOGY

Infection with dermatophytes, mycobacterium, histoplasma, viruses, bacteria, or parasites (e.g., lice):

- Dermatitis such as contact, stasis, or eczematous.
- Other causes include retained sutures, ionizing radiation, and blunt trauma.

PATHOGENESIS

Unknown but possible explanations include:

- Abnormal immune recognition of autologous skin antigens
- Stimulation of normal T cells by altered skin constituents
- Lowering of the threshold for skin irritation
- Dissemination of infectious antigen resulting in a secondary response
- Hematogenous dissemination of cytokines from the primary site of inflammation

CLINICAL FEATURES

- Usually associated with exacerbation of primary dermatitis.
- Characteristics of the rash in ID reaction include:
  1. Sudden onset of rash appearing within 1 or 2 wk of primary inflammation
  2. The rash could not be identified as a common dermatosis
  3. Lesions are most commonly seen in the side of the fingers. However, ID reaction could be generalized. Particularly in patients with stasis dermatitis, it appears in forearms, thighs, legs, trunk, face (Fig. E2), hands, neck, and feet in descending order of frequency
  4. Extremely pruritic
  5. Often symmetric in distribution
  6. Most of the time it is vesicular
- It resolves upon treatment of primary inflammation.

FIG. E1 ID reaction. Papular eruption of the face associated with severe tinea infection of the hand. (From Kliegman RM: *Nelson Textbook of Pediatrics,* ed 21, Philadelphia, 2020, Elsevier.)

DIAGNOSIS

- It is a clinical diagnosis. The diagnosis should not be made conclusively unless there is an acute inflammatory process at a distant site and the ID reaction disappears shortly after the acute inflammation is controlled.
- Fungus, when suspected, could be isolated only from the primary site by using potassium hydroxide or by using fungal culture.
- At times, skin biopsy is done. The biopsy findings are not pathognomonic for ID reaction. These include spongiotic epidermal vesicles associated with superficial perivascular lymphocytic infiltration of dermis, which may also contain scattered eosinophils. Whereas most of the lymphocytes in the epidermis are CD3 and CD8 T cells, those in the dermis are primarily CD4 cells.
- Patch testing may be considered to exclude primary or secondary allergic contact dermatitis.

DIFFERENTIAL DIAGNOSIS

- Atopic dermatitis
- Contact dermatitis
- Drug eruptions
- Dyshidrotic eczema
- Folliculitis
- Scabies
- Dermatophytic infection
- Viral exanthema

TREATMENT

- The treatment is best directed toward the inciting cause.
- Medications used for symptomatic treatment of ID reaction include:
  1. Local or systemic steroids
  2. Local or systemic antihistamines
  3. Topical or systemic antibiotics for secondary bacterial infection
  4. Aluminum sulfate or calcium acetate for weeping skin lesions
  5. Rarely, local or systemic macrolactams (e.g., cyclosporine)

COMPLICATION

Secondary bacterial infection

PROGNOSIS

It almost always resolves within days when the primary dermatitis is adequately treated.

PATIENT & FAMILY EDUCATION

Treat primary dermatitis promptly.

AUTHOR: **Fred F. Ferri, MD**

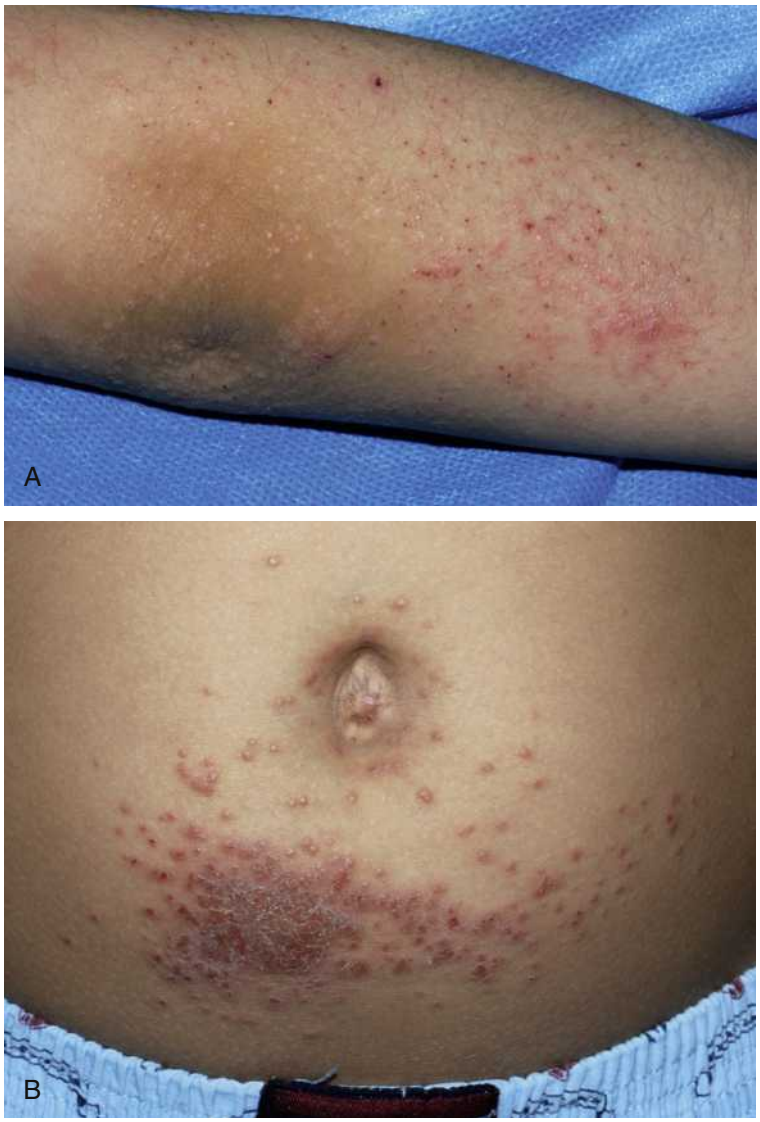

FIG. E2 ID reactions in children due to allergic contact dermatitis (ACD) to nickel. A, Multiple flat-topped papules, several of which have been excoriated, in addition to patches of eczema. **B,** Square-shaped area of ACD due to nickel in a buckle with an associated ID reaction. The latter consists of edematous crusted papules that are separate from the area of direct nickel contact. (From Bolognia JL et al: *Dermatology,* ed 4, Philadelphia, 2018, Elsevier.)

Idiopathic Intracranial Hypertension

BASIC INFORMATIONS

DEFINITION

Idiopathic intracranial hypertension (IIH) is a syndrome of increased intracranial pressure (ICP) without either underlying hydrocephalus or mass lesion and with normal cerebrospinal fluid analysis.

SYNONYMS

Pseudotumor cerebri
IIH
Benign intracranial hypertension

ICD-10CM CODE
G93.2 Benign intracranial hypertension

EPIDEMIOLOGY & DEMOGRAPHICS

- 90% of affected persons are women of childbearing age with elevated body mass index (BMI).

INCIDENCE:

- General population: 1 to 2 per 100,000 (including children)
- Women (obese females in reproductive age group): 20 per 100,000
- Men: 0.3 to 1.5 cases per 100,000
- Female:male ratio 9:1
- More than 90% of IIH patients are obese
- Mean age at diagnosis is 30 yr

RISK FACTORS:

- Obesity
- Medications: Vitamin A and retinoids (used in treatment of acne and leukemia), chronic oral medications used for acne (tetracycline, minocycline), glucocorticoid use or withdrawal
- Systemic conditions: Chronic kidney disease, polycystic ovarian syndrome, obstructive sleep apnea

PHYSICAL FINDINGS & CLINICAL PRESENTATION

SYMPTOMS:

- Headaches: Generalized, throbbing, slowly progressive, worse with straining maneuvers, worse in the morning
- Transient visual obscuration: A brief blurring of vision or scotomata lasting <30 sec; occurs with postural changes, Valsalva maneuver; may be monocular
- Double vision: Usually due to sixth nerve palsy
- Pulsatile tinnitus: Described as a "whooshing sound" that is synchronous with heartbeat; classic symptom that indicates raised ICP
- Photopsia: Lights, sparkles in the eyes
- Pain: Mainly retroorbital. Pain may also be located in the shoulders or neck. Could be present without a headache. Low back pain with radiation along the lower extremities (radicular) may be seen

SIGNS:

- Papilledema: Seen in virtually all cases; usually bilateral but may be asymmetric
- Sixth nerve palsy: Seen in approximately 10% to 20% of patients; considered to be a nonlocalizing neurologic sign
- Visual field defects: Include enlarged physiologic blind spot, nasal field defects, and constricted visual fields. Up to 90% of patients exhibit some form of visual loss on perimetry
- Loss of central vision: End result of longstanding and untreated IIH

ETIOLOGY

- The exact etiology remains unknown.
- Proposed pathophysiologic mechanisms underlying the raised ICP include increased brain water content, excess cerebrospinal fluid (CSF) production, reduced CSF absorption, and increased cerebral venous pressure either alone or in combination.
- Another proposed mechanism includes abnormal vitamin A metabolism leading to increased CSF retinol levels and decreased CSF absorption at the arachnoid granulations.

DIAGNOSIS

DIAGNOSTIC CRITERIA

MODIFIED DANDY CRITERIA FOR DIAGNOSIS OF IIH:

- Signs and symptoms of raised ICP (listed above)
- Absence of localizing focal neurologic signs (except sixth nerve palsy)
- CSF opening pressure of 25 cm H_2O or more with normal CSF composition
- Normal neuroimaging studies (MRI and magnetic resonance venography [MRV] brain) including absence of cerebral venous thrombosis; stenosis of transverse sinuses may be seen in IIH without thrombosis

DIFFERENTIAL DIAGNOSIS

- IIH is a diagnosis of exclusion and criteria listed above have to be satisfied.
- Causes of papilledema include intracranial space-occupying lesions such as tumors, abscesses, hematoma; venous sinus thrombosis; low CSF pressure; carcinomatous meningitis; chronic meningitides such as neurosarcoidosis, central nervous system (CNS) lupus, neurosyphilis, cryptococcal meningitis, and tuberculous meningitis.

WORKUP

- Neuroimaging studies: MRI of brain with MR head venogram; CT head and CT head venogram when MRI of brain cannot be obtained.
- Lumbar puncture: CSF opening pressure (OP) should be obtained in the lateral decubitus position with the legs stretched and patient relaxed. Diagnosis is confirmed by a CSF opening pressure >250 mm H_2O with normal fluid composition.
- Ophthalmologic examination: All patients with IIH need an ophthalmologic examination including visual fields at baseline and follow-up visits. Enlargement of the blind spot and reduction in peripheral fields are commonly seen.

LABORATORY TESTS

CSF analysis shows normal protein, glucose, and cell count.

IMAGING STUDIES

- MRI of the brain to rule out underlying structural lesions
  1. Absence of specific causes of raised ICP listed previously
  2. Empty sella sign often associated with chronic raised ICP but not pathognomonic
- MR or CT venography to exclude cortical venous thrombosis
  1. May show transverse sinus stenosis in IIH without thrombosis. Absence of specific causes of raised ICP listed previously
- CT head
  1. May show slit-like ventricles

TREATMENT

NONPHARMACOLOGIC THERAPY

- Treatment is aimed primarily at preservation of vision
- Weight loss in obese patients
- Continuous positive airway pressure if obstructive sleep apnea is suspected

ACUTE GENERAL Rx

- Acetazolamide 250 mg to 4 g per day: Reduces CSF production by inhibition of carbonic anhydrase, occasionally causing anorexia and resultant weight loss. Dose can be increased to a maximum of 4 g a day in resistant cases with visual loss.
- Furosemide 40 to 120 mg/day in divided doses: Apparent mechanism of action is by reduced sodium transport, leading to decreased total CSF volume.
- Topiramate 100 to 400 mg/day: Reported to be effective in treatment of IIH. It is a weak carbonic anhydrase inhibitor with weight loss as one of its primary side effects.
- Serial lumbar punctures (LP): SHOULD NOT BE CONSIDERED AS STANDARD TREATMENT OF IIH. LP should be attempted in patients with severe headaches resistant to medical therapy. Goal is to reduce spinal fluid pressure to allow immediate reduction in headache severity. This treatment should be reserved for the most resistant cases and should be used as a conduit to future surgical intervention. Serial LP should not be used as treatment for IIH with progressive visual loss.

CHRONIC Rx

Surgical intervention is indicated in cases of treatment failure and progressive visual loss.

- Optic nerve fenestration: Preferred for patients with visual loss and easily controlled headaches. Proposed mechanism is decompression of the optic nerve. Highly effective; however, has been associated with significant number of failure rates
- CSF shunting: Neurosurgical procedure; performed in patients with significant visual deterioration and difficult-to-control headaches. Provides rapid improvement in

symptoms; however, reported to have significant rates of shunt revisions because of shunt malfunction

DISPOSITION

- IIH is a potentially blinding condition, with severe vision loss in 5% to 10% of patients; patients should be co-managed by neurologists and ophthalmologists (preferably by a neuro-ophthalmologist). Monthly follow-up is essential until visual fields stabilize. More frequent follow-up is needed in patients with severe papilledema or visual loss at presentation.
- All patients with IIH should undergo MR or CT venography to rule out the possibility of venous sinus thrombosis.

REFERRAL

- Neuroophthalmology for serial evaluation of visual fields and fundus photographs
- Nutritionist for weight loss
- General neurologist for the initial workup and eventual treatment of raised ICP

PEARLS & CONSIDERATIONS

COMMENTS

- IIH is a potentially blinding condition.
- IIH is a diagnosis of exclusion.
- IIH is a disease of young obese women of childbearing age (90% of affected patients).

PREVENTION

Maintenance of ideal body weight is one of the best preventive mechanisms for avoidance of IIH. However, it does occur in patients with normal body weight. In these cases there are no known preventable risk factors.

PATIENT & FAMILY EDUCATION

The combination of weight loss and medical therapy is highly effective in treatment of IIH. Given that most patients with IIH are young and otherwise healthy, high success rates can be accomplished.

SUGGESTED READINGS

Biousse V et al: Update on the pathophysiology and management of idiopathic intracranial hypertension, *J Neurol Neurosurg Psychiatry* 83:488, 2012.

NORDIC Idiopathic Intracranial Hypertension Study Group Writing Committee et al: Effect of acetazolamide on visual function in patients with idiopathic intracranial hypertension and mild visual loss: the idiopathic intracranial hypertension treatment trial, *J Am Med Assoc* 311(16):1641-1651, 2014.

BASIC INFORMATION

DEFINITION

Idiopathic pulmonary fibrosis (IPF) is a specific form of chronic fibrosing interstitial pneumonia with histopathologic characteristics of usual interstitial pneumonia (UIP) occurring in the absence of an identifiable cause of lung injury. Clinically, it is characterized by progressive parenchymal scarring and loss of pulmonary function.

SYNONYMS

Cryptogenic fibrosing alveolitis
IPF
Pulmonary fibrosis
Usual interstitial pneumonia

ICD-10CM CODE
J84.112 Idiopathic pulmonary fibrosis

EPIDEMIOLOGY & DEMOGRAPHICS

- Incidence: 7 to 16 cases/100,000 persons worldwide. Clinically IPF affects >50,000 people in the U.S. and accounts for 20% to 30% of interstitial lung diseases. It is the most common idiopathic interstitial pneumonia
- Most commonly presents in sixth and seventh decades
- More common in men than women
- More common in current and past smokers
- Familial forms account for 3% to 25% of cases. Genetic variants: Include mutations in surfactant protein C and telomerase as well as polymorphisms of the *MUC5B* gene
- No distinct geographic distribution; no clear racial predilection

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most present with gradual onset (>6 mo) of exertional dyspnea and nonproductive cough. Progressive dyspnea is usually the most prominent symptom. Cough affects up to 80% of patients with IPF, is frequently disabling, and lacks effective therapy.
- Fine bibasilar inspiratory crackles, "velcro inspiratory crackles" in >80% of patients, with progression upward as the disease advances.
- Clubbing is found in 25% to 50% of patients.
- Cyanosis and right heart failure (cor pulmonale) may occur late in the disease course.
- There are no extrapulmonary manifestations beyond clubbing and complications of right heart failure. Fever and wheezing are rare and suggest alternative diagnosis.
- Fig. E1 is a chest radiograph showing diffuse bilateral lower lung predominant reticular opacities in a patient with IPF.

ETIOLOGY

- Unknown. Fig. 2 illustrates a proposed pathogenetic sequence in IPF.
- Cigarette smoking, environmental exposures, gastroesophageal reflux, and microaspiration have been associated with IPF.
- Aberrant tissue repair and fibrosis are believed to play a greater role in the pathogenesis than generalized inflammation. Immune system activation and increased vascular permeability contribute to the underlying pathology.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Sarcoidosis
- Drug-induced interstitial lung disease
- Pulmonary manifestations of collagen vascular diseases (e.g., rheumatoid arthritis [RA], systemic sclerosis); ILD may be an initial sign of disease
- Hypersensitivity pneumonitis (HP)
- Occupational exposures (e.g., asbestos, silica) may cause pneumoconiosis that mimics IPF
- Other idiopathic interstitial pneumonias:
  1. Desquamative interstitial pneumonia (DIP)
  2. Respiratory bronchitis–interstitial lung disease (RB-ILD)
  3. Acute interstitial pneumonia (AIP)
  4. Nonspecific interstitial pneumonia (NSIP)
  5. Cryptogenic organizing pneumonia (COP)
- IPF is considered a diagnosis of exclusion

WORKUP

- Almost all patients have abnormal chest radiograph at presentation, with bilateral reticular opacities most prominent in the periphery and lower lobes. Peripheral honeycombing may be seen.
- High-resolution CT scan (Fig. 3) is the best diagnostic test. It shows patchy peripheral reticular abnormalities with intralobular linear opacities, irregular septal thickening, subpleural honeycombing, and minimal, if any, ground-glass opacities.
- Pulmonary function testing shows restrictive pattern and reduced carbon monoxide diffusion into the lung.
- Six-minute walk test may show reduced exercise tolerance and/or exertional hypoxia.
- Laboratory abnormalities (nondiagnostic): Mild anemia; increases in erythrocyte sedimentation rate, lactate dehydrogenase, C-reactive protein; low titer antinuclear antibody seen in up to 30% of patients.
- The need for autoimmune serologies is not well defined. Any signs or symptoms that might suggest underlying autoimmunity should be evaluated fully.

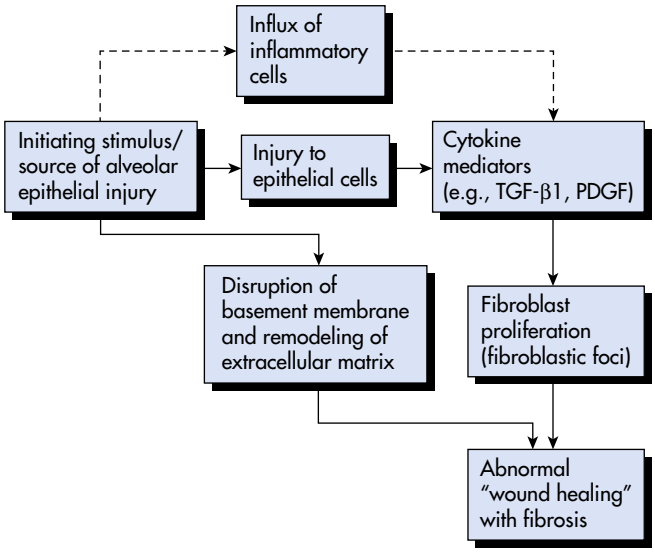

FIG. 2 Proposed pathogenetic sequence in idiopathic pulmonary fibrosis. Dotted lines indicate that although there is an influx of inflammatory cells, this is not thought to be a primary component of pathogenesis. *PDGF,* Platelet-derived growth factor; *TGF-β1,* transforming growth factor-β1. (From Weinberger SE: *Principles of pulmonary medicine,* ed 7, Philadelphia, 2019, Elsevier.)

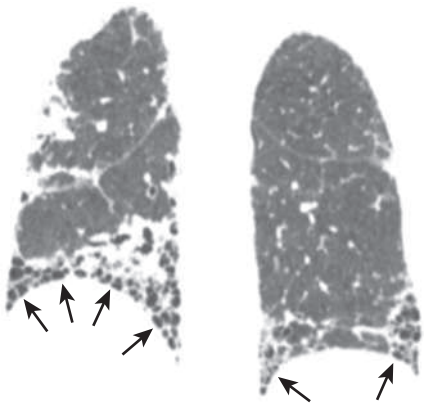

FIG. 3 Pulmonary fibrosis, honeycombing, and a usual interstitial pneumonia (UIP) pattern in idiopathic pulmonary fibrosis (IPF). Coronal high-resolution computed tomography reconstruction shows honeycombing *(arrows)* with a basal and subpleural predominance. This is typical of a UIP pattern. (Webb WR, Brant WE, Major NM: *Fundamentals of body CT,* ed 4, Philadelphia, 2015, Saunders.)

TABLE 1 Summary of Histologic Findings for Immunologic Lung Diseases

Disease	Histology
Granulomatous	
Foreign body, inorganic dust	Simple granuloma
Hypersensitivity pneumonitis	Granulomas with $CD4^+$/$CD8^+$ T cells; interstitial edema; fibrosis in later stages
Infections	
Tuberculosis	Caseating granulomas
Sarcoidosis	Noncaseating granulomas
Granulomatous Vasculitides	
Wegener granulomatosis	Necrotizing granulomas involving vasculature
Churg-Strauss syndrome	Necrotizing granulomas involving vasculature
Eosinophilic pneumonias	Granulomas with eosinophilic predominance; interstitial edema
Histiocytosis X	Granulomas with Langerhans cells
Alveolitic	
Drug-associated injury	Interstitial edema with inflammatory cells
Goodpasture syndrome	Linear staining of basement membrane with anti-IgG antibodies typically seen on renal biopsy; interstitial edema with inflammatory cells
Idiopathic Interstitial Pneumonias	
Idiopathic pulmonary fibrosis	Interstitial edema and/or fibrosis with inflammatory cells; patchy fibrotic change
Desquamative interstitial pneumonia	Interstitial edema with sparse inflammatory cells; mild diffuse fibrotic change
Idiopathic nonspecific interstitial pneumonia	Thickened interstitium with inflammatory cells; some patchy fibrosis
Acute interstitial pneumonia	Diffuse alveolar damage with thickened fibrotic interstitium; proliferating fibroblasts
Respiratory bronchiolitis–associated interstitial lung disease	Macrophages infiltrating distal bronchioles
Cryptogenic organizing pneumonia	Chronically inflamed alveoli with granulation tissue in bronchioles and macrophages in alveoli
Lymphocytic interstitial pneumonia	Diffuse lymphocytic and plasma cell infiltration; minimal alveolar injury
Idiopathic pleuroparenchymal fibroelastosis	Diffuse alveolar damage with fibrosis

From Sellke FW et al: *Sabiston & Spencer surgery of the chest,* ed 9, 2016, Elsevier.

- There is a limited role for bronchoalveolar lavage either in diagnosis or monitoring IPF.
- Gold standard for diagnosis is lung biopsy (open thoracotomy or video-assisted thoracoscopy). Hallmark features: Heterogeneous distribution of parenchymal fibrosis against background of mild inflammation (UIP). In patients with characteristic chest CTs, lung biopsies can be avoided.
- When there is uncertainty, lung biopsy is critical to distinguish IPF from diseases with better prognosis and different treatment options.
- Table 1 summarizes histologic findings for immunologic diseases.
- A multidisciplinary approach involving the collaboration of pulmonology, radiology, and pathology to secure a diagnosis is considered standard of care.

Rx TREATMENT

- Two FDA-approved oral therapies have similar proven efficacy in slowing disease progression, but neither elevates patients' perceived quality of life, and both are associated with substantial side effects. Combination therapy with both medications has not been investigated. Pirfenidone is an antifibrotic medication without a known mechanism of action. It is taken three times a day with food. Its major side effects are nausea, abdominal discomfort, and photosensitivity. LFTs require periodic surveillance.
- Nintedanib is a tyrosine kinase inhibitor taken twice daily. Its major side effect is diarrhea, which often resolves. LFTs also need to be followed.
- Additional new therapies are being investigated and are in phase I, II and III testing. Recent trials have shown that adding sildenafil to nintedanib did not improve quality of life or lessen 24-week mortality.[1]
- In patients with advanced disease, treatment options include supportive care (pulmonary rehabilitation, supplemental oxygen, influenza and pneumococcal vaccination) and potential lung transplantation.
- Treatment of asymptomatic gastroesophageal reflux may be reasonable given association between pulmonary fibrosis and reflux or microaspiration.
- Lung transplantation is the only therapy shown to prolong survival in IPF. Guidelines for transplantation by pulmonary disease are summarized in Box 1. Box 2 summarizes absolute contraindications to lung transplantation. Posttransplant 5-yr survival for IPF patients is approximately 50% to 60%. Median survival time is longer after bilateral lung transplantation than single lung transplantation but is associated with more complications during the first yr.
- Acute exacerbation of IPF, defined as worsening dyspnea (<1 mo), the presence of new opacities on radiograph, and the lack of evidence of infection, has a yearly incidence of 10% to 20%. Progressive respiratory failure may require mechanical ventilation; however, a palliative care approach is often chosen instead. Treatment for exacerbations typically includes high-dose corticosteroids and broad-spectrum antibiotics, although the efficacy of this approach is unproven and questionable.

[1]Peljto AL et al: Association between the MUC5B promoter polymorphism and survival in patients with idiopathic pulmonary fibrosis, *JAMA* 309(21):2232-2239, 2013.

DISPOSITION

- Spontaneous remissions do not occur, although long periods of stability can occur.
- Natural history includes progressive loss of pulmonary function. Predictors of poor outcome include older age, male gender, moderately to severely abnormal PFTs and presence of pulmonary hypertension.
- There is an increased risk of lung cancer.
- Mean survival after the diagnosis of biopsy-confirmed IPF is 3 to 5 yr, although with new therapies available, survival is less defined.
- Respiratory failure is the most common cause of death.

REFERRAL

- To pulmonologist for review of abnormal chest imaging and establishing diagnosis.
- Encouraging participation in clinical trials is a priority.
- Early referral for lung transplant.
- Later stage management should include palliative care or hospice services.

PEARLS & CONSIDERATIONS

- The course is progressive, with a high mortality rate. The most common cause of death in IPF is respiratory failure.
- Critical to differentiate IPF from other interstitial lung diseases because prognosis and treatment approaches differ.
- Two oral therapies shown to slow disease progression are available. Combination therapy has not been investigated. Additional novel treatments are being investigated.[2]

Idiopathic Pulmonary Fibrosis (Patient Information)

AUTHOR: **Peter LaCamera, MD**

[2]Kolb M et al: Nintedanib plus sildenafil in patients with idiopathic pulmonary fibrosis, *N Engl J Med* 379:1722-31, 2018.

BOX 1 Guidelines for Transplantation by Pulmonary Disease

Chronic Obstructive Pulmonary Disease
Patients with a BODE index* of 7 to 10 or at least one of the following:
- History of hospitalization for exacerbation associated with acute hypercapnia (P_{CO_2} >50 mm Hg)
- Pulmonary hypertension or cor pulmonale, or both, despite oxygen therapy
- FEV_1 <20% predicted and either DLCO <20% predicted or homogeneous distribution of emphysema

Cystic Fibrosis and Other Causes of Bronchiectasis
Oxygen-dependent respiratory failure
Hypercapnia
Pulmonary hypertension

Idiopathic Pulmonary Fibrosis and NSIP
Histologic or radiographic evidence of usual interstitial pneumonia and any of the following:
- DLCO <39% predicted
- 10% or greater decrement in FVC during 6 months of follow-up
- A decrease in pulse oximetry below 88% during a 6-MWT
- Honeycombing on high-resolution computed tomography (fibrosis score >2)

Histologic evidence of NSIP and any of the following:
- DLCO <35% predicted
- 10% or greater decrement in FVC or 15% decrease in DLCO during 6 months of follow-up

Pulmonary Arterial Hypertension
Persistent New York Heart Association class III or IV on maximal medical therapy
Low (<350 m) or declining 6-MWT
Failing therapy with intravenous epoprostenol or equivalent
Cardiac index <2 L/min/m^2
Right atrial pressure >15 mm Hg

*BODE index includes body mass index, degree of airflow obstruction (assessed by percent predicted FEV_1), degree of dyspnea (assessed by the modified Medical Research Council [MMRC] dyspnea scale), and exercise capacity (assessed by the 6-minute walk distance). The index increases as body mass index, FEV_1, and distance walked decrease and as the MMRC scale increases.
6-MWT, 6-minute walk test; *DLCO*, diffusing capacity of the lungs for carbon monoxide; *FVC,* forced vital capacity; *NSIP,* nonspecific interstitial pneumonia.
From Sellke FW, del Nido PJ, Swanson SJ: *Sabiston & Spencer surgery of the chest,* ed 9, Philadelphia, 2016, Elsevier.

BOX 2 Absolute Contraindications to Lung Transplantation

- Malignancy within the last 2 yr, with the exception of cutaneous squamous and basal cell carcinomas; the role of lung transplantation in patients with focal pulmonary adenocarcinoma in situ (formerly known as *bronchoalveolar carcinoma*)
- Untreatable advanced dysfunction of another organ system (heart, liver, kidney); coronary artery disease not amenable to percutaneous intervention or bypass grafting, or associated with significant impairment of left ventricular function, is an absolute contraindication to lung transplantation, but heart-lung transplantation could be considered in some cases
- Incurable chronic extrapulmonary infection, including chronic active viral hepatitis B, hepatitis C, and human immunodeficiency virus
- Significant chest-wall or spinal deformity
- Nonadherence or inability to follow through with medical therapy or office follow-up
- Untreatable psychiatric or psychological condition associated with the inability to cooperate or comply with medical therapy
- Absence of a consistent or reliable social support system
- Substance addiction (alcohol, tobacco, or narcotics) that is either active or has been within the last 6 mo

From Sellke FW, del Nido PJ, Swanson SJ: *Sabiston & Spencer surgery of the chest,* ed 9, Philadelphia, 2016, Elsevier.

IgA Nephropathy ALG

BASIC INFORMATION

DEFINITION

Immunoglobulin A (IgA) nephropathy is a proliferative glomerulonephritis associated with predominant deposition of IgA in the mesangium. IgA deposition may occur in isolation or with IgG, IgM, or both, and often with complement protein C3.

SYNONYMS

Berger disease
IgAN
IgA vasculitis

ICD-10CM CODES

N02.1	Recurrent and persistent hematuria with focal and segmental glomerular lesions
N02.3	Recurrent and persistent hematuria with diffuse mesangial proliferative glomerulonephritis
N02.5	Recurrent and persistent hematuria with diffuse mesangiocapillary glomerulonephritis
N02.7	Recurrent and persistent hematuria with diffuse crescentic glomerulonephritis
N02.8	Recurrent and persistent hematuria with other morphologic changes

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: IgA nephropathy (IgAN) is the most common primary glomerulopathy worldwide. The annual incidence of IgAN in the U.S. is about 1 to 4 cases per 100,000 person-yr. There is a West-to-East increase in incidence and prevalence. There is a very low incidence in Africa relative to the U.S. and a higher incidence in East Asia. In Japan, the incidence is 10 times as high as in the U.S. In Europe, there is a South-to-North increase in incidence, with Nordic populations having more than a twofold greater risk than southern Europeans. Because IgA is the primary gut antibody, the increased incidence and prevalence in Asia has been postulated to be related to geographic differences in dietary exposure to antigens and genetic factors as discussed below.
PREVALENCE: Prevalence data ranges from 1.3% to 16% in the general population based on autopsy studies that demonstrate renal IgA deposits. In most reports, prevalence rates are expressed as a percentage of cases of primary glomerulonephritis or as a percentage of total series of renal biopsies. The prevalence rate in kidney biopsies is lowest in the Middle East (5%), 10% to 35% in Europe, 20% in the U.S., and 32% to 54% in Japan and China, reflecting the West-to-East increase in incidence and prevalence. Lower rates may be biased by a more conservative approach by U.S. nephrologists reluctant to perform kidney biopsies in asymptomatic patients with minimal renal abnormalities compared with screening programs in Japan.
PREDOMINANT SEX AND AGE: IgAN is most prevalent in the second and third decades of life with a male:female ratio of 2:1 in the U.S. and 3:1 ratio in Europe. In East Asia, the male:female ratio is closer to 1:1.
GENETICS AND PATHOGENESIS: The primary defect is systemic aberrant glycosylation resulting in galactose-deficient IgA1 (Gd-IgA1) in the serum, a heritable trait in diverse racial and ethnic groups. The genetic predisposition is confirmed by the presence of elevated Gd-IgA1 serum levels in a quarter of relatives of patients with IgAN . The Gd-IgA1 binds autoantibody IgG generating nephritogenic immune complexes.

Although a sporadic disease in more than 90% of cases, recent genome-wide association studies have identified 6% to 8% of cases with at least 15 susceptibility loci, with the strongest signal from the major histocompatibility complex (MHC) region of chromosome 6. Certain loci are more prevalent in Asia compared with the U.S. and Europe. Geospatial analysis of the genetic risk in 85 worldwide populations mirrors the West-to-East worldwide pattern and South-to-North European distribution of the disease. In addition, Asian Americans have a fourfold higher end-stage renal disease incidence than European Americans and a seven fold higher end-stage renal disease incidence than African Americans, reflecting the genetic basis for this disease. An interesting theory is that the greater prevalence of risk alleles in East Asians may have been selected to protect against intestinal helminthic infestation.

There is abnormal alternative pathway complement activation in IgAN. Recent studies have examined factor H-related (FHR) proteins that interfere with factor H, a major negative regulator of C3 activation. FHR-1 proteins are elevated in IgAN and associated with progressive disease. Patients with two copies of the CFHR1 gene had greater FHR-1 levels, implicating potential genetics of factor H dysregulation causing or worsening IgA nephropathy. More recently the role of B-cell activation factor (BAF) of the tumor necrosis factor family and T-cell cytokine APRIL are considered important to disease pathogenesis.
RISK FACTORS: There are greater associations in Asians, whites, and Native Americans, but IgAN is relatively rare in African Americans. IgAN is more common in males outside East Asia.

Renal outcomes: The most robust risk factors and predictors of poor renal outcomes include older age, hypertension, proteinuria >1 g/day, and decreased glomerular filtration rate (GFR) at time of diagnosis. Lower hemoglobin and albumin recently have been shown as robust poor outcome risk factors. Pathologic risk factors for poor renal outcomes include increased mesangial cellularity, segmental glomerulosclerosis, and tubular atrophy and interstitial fibrosis (see Box E1).

BOX E1 Prognostic Markers in IgA Nephropathy

Clinical
Poor prognosis
- Increasing age
- Severity of proteinuria
- Hypertension (increased systolic blood pressure)
- Renal impairment (decreased GFR)
- Decreased serum albumin
- Decreased hemoglobin
- Persistent microscopic hematuria

Good prognosis
- Recurrent macroscopic hematuria

Histopathologic (Oxford Classification)
Poor prognosis
- Increased mesangial cellularity
- Segmental glomerulosclerosis
- Tubular atrophy/interstitial fibrosis
- Crescents

No impact on prognosis
- Endocapillary hypercellularity

GFR, Glomerular filtration rate.
From Canetta PA et al: Glomerular diseases: emerging tests and therapies for IgA nephropathy, *Clin J Am Soc Nephrol* 9:617, 2014; and Lv J et al: Evaluation of the Oxford Classification of IgA nephropathy: a systematic review and meta-analysis, *Am J Kidney Dis* 62(5):891, 2013.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- 75% of children and young adults present with macroscopic hematuria often associated with upper respiratory infection or gastrointestinal illness. Older adults present with microscopic hematuria, proteinuria, and hypertension.
- Loin pain may be associated with macroscopic hematuria. This symptom should not be confused with the much more rare disorder termed "loin pain hematuria syndrome."
- Physical findings are usually unremarkable. Hypertension is present in 20% to 30% of patients with chronic kidney disease and edema is seen in the 5% of patients with nephrotic-range proteinuria.
- IgAN presents as acute kidney injury due to hemoglobin toxicity from macroscopic hematuria in 5% of patients and as chronic kidney disease in 10% to 20% of patients.

ETIOLOGY

- Most cases are idiopathic/primary. IgA vasculitis (formerly Henoch-Schönlein purpura) may represent a more systemic, vasculitic form of IgAN.
- Secondary causes of IgAN (Table E1): Hepatitis B; alcoholic cirrhosis; celiac disease; inflammatory bowel disease (IBD); psoriasis; sarcoidosis; cystic fibrosis; cancer of the lungs, larynx, or pancreas; HIV infection; systemic lupus erythematosus; rheumatoid arthritis; diabetic nephropathy; Sjögren syndrome; and Reiter syndrome. Given the role of IgA in the gut, aside from IBD, infections in the GI tract have been associated with IgAN or flares of the disease.
- The four-hit pathogenesis model is demonstrated in Fig. E1. The first hit with high heritability is abnormal glycosylation that produces galactose-deficient IgA1 (Gd-IgA1). This abnormal glycosylation is mediated by changes in the activity of a key enzyme,

TABLE E1 Classification of Immunoglobulin A (IgA) Nephropathy

C1GALT1. In turn, this enzyme is regulated by microRNAs. The second hit is production of anti-glycan antibodies that recognize epitopes on Gd-IgA1, forming immune complexes that deposit in the mesangium as the third hit. IgA also stimulates production of growth factors such as PDGF and IGF-1, leading to mesangial expansion. The activation of complement and release of inflammatory cytokines from activated leukocytes represents the fourth and final hit.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

The differential diagnosis is the group of glomerular, hematuric diseases.

- IgA vasculitis (Henoch-Schönlein purpura)
- Hereditary nephritis
- Thin glomerular basement membrane disease
- Lupus nephritis
- Vasculitis
- Post infectious nephritis
- Secondary causes associated with IgA nephropathy as mentioned above

WORKUP

- Diagnosis is suspected based on clinical history and laboratory data. Episodes of gross hematuria with upper respiratory infections and urinalysis demonstrating dysmorphic hematuria and RBC casts with negative serologies for other glomerulonephritides (e.g., lupus and vasculitis) strongly point to the diagnosis. Although serum IgA levels are elevated in 50% of patients, their sensitivity and specificity are low; diagnosis is confirmed by kidney biopsy showing predominant or codominant IgA deposits in the mesangium.
- To standardize diagnosis and provide prognostication, the pathology is scored via the Oxford IgAN MEST classification that evaluates **M**esangial hypercellularity, **E**ndocapillary hypercellularity, **S**egmental glomerulosclerosis, and **T**ubular atrophy/interstitial fibrosis.
- Prognosis is excellent with normal renal function and low proteinuria; accordingly, kidney biopsy is restricted to patients with sustained proteinuria >1 g/day or worsening kidney function.

LABORATORY TESTS

- Urinalysis variably demonstrates protein, dysmorphic red blood cells, and red blood cell casts.
- Serum creatinine may be elevated.
- Urine protein-to-creatinine ratio reveals mild increases in proteinuria.
- Serum IgA is elevated in only 50% of patients, but has little clinical utility.

Rx TREATMENT

Although initially considered a benign disease, IgAN is recognized as a common cause of kidney failure. Currently there is no cure.

NONPHARMACOLOGIC THERAPY

- Weight reduction in overweight or obese patients
- Smoking cessation

ACUTE & CHRONIC GENERAL Rx

- Antihypertensive therapy, preferably with angiotensin-converting enzyme (ACE) inhibitors or angiotensin receptor blockers (ARBs). The goal blood pressure is <125/75 mm Hg if proteinuria is >1 g/day and <130/80 if <1 g/day, per international guidelines. Dual RAAS blockade is not recommended due to risk of hyperkalemia.
- Patients with recurrent gross hematuria, isolated microscopic hematuria, no or minimal proteinuria (<1 g/day), normal blood pressure, and normal kidney function should be monitored every 6 to 12 mo to evaluate disease progression. Fish oil may be considered but has limited supporting data.
- If bouts of recurrent macroscopic hematuria are associated with tonsillitis, tonsillectomy may benefit these patients; however, this treatment is controversial..
- Patients with persistent proteinuria >1 g/day with or without hypertension are treated with ACE inhibitors or ARBs.
- Based on three randomized, controlled trials, a 6-mo regimen of glucocorticoid steroids was advocated for patients with good kidney function with persistent proteinuria of >1 g/day, despite ACE inhibitor or ARB administration and fish oil after 6 mo. However, a recent, prospective, randomized, controlled trial (STOP-IgAN) showed no difference in decline in GFR with corticosteroids in subnephrotic patients followed for 3 yr, with increased infections, glucose intolerance, and obesity. Another recent multicenter study (TESTING) of 262 subnephrotic patients randomized to steroids versus placebo showed potential renal benefit of steroid treatment, but was stopped early due to excess infections in the steroid group (14.7% vs 3.2%). Thus, definite conclusions regarding steroid treatment have not been established. Patients with nephrotic syndrome and relatively preserved kidney function on maximal RAAS blockade are treated with steroids for a 6-mo course, especially if there is disease progression. Steroid treatment is not indicated if significant chronic disease is demonstrated on renal biopsy or if the GFR is <20 ml/min per 1.73 m^2.
- Rapidly progressive glomerulonephritis, in the absence of severe fibrosis on kidney biopsy, is treated with pulse steroids followed by oral steroids, combined with cyclophosphamide for the first 2 to 3 mo. This initial regimen is followed by oral steroids and azathioprine for 2 yr as a maintenance treatment.

- Patients with acute kidney injury require a kidney biopsy to differentiate acute tubular necrosis from pigment nephropathy that requires only supportive therapy from crescentic IgA nephropathy that is treated with aggressive medical management.
- Kidney transplantation is the treatment of choice for end-stage renal disease. Although the recurrence rate of IgA nephropathy in the transplant is 50%, allograft loss from recurrent IgA nephropathy is only 5%.
- Statins are indicated for all IgA nephropathy patients with dyslipidemia, hypertension, and other cardiovascular risks.
- The roles of mycophenolate, rituximab, and plasmapheresis are not clearly defined given lack of evidence.
- A phase 2b clinical trial (NEFIGAN) showed potential benefit from use of budesonide.
- Future treatments may include targeted immunosuppression of the gut and modification of abnormal complement activation.

COMPLEMENTARY & ALTERNATIVE MEDICINE

The role of fish oil is controversial. One large, randomized, placebo-controlled study showed benefit, although many small, randomized studies showed no benefit. The recommendation for mild disease is that fish oil is optional for patients. International consensus guidelines recommend fish oil along with ACE inhibitors/ARBs if proteinuria is >1 g/day.

DISPOSITION/PROGNOSIS

- Complete remission occurs in <10% of patients.
- End-stage renal failure develops in 12% of patients followed for 5 yr, in 15% to 20% within 10 yr, and in 20% to 40% within 20 yr. Prognostic markers in IgAN are described in Box E1.
- Poor prognostic indicators include hypertension, extent of renal insufficiency, extent of proteinuria, and certain histologic changes seen in renal biopsy such as crescents, increased mesangial cells, glomerulosclerosis, and tubulointerstitial fibrosis or atrophy.
- Potential future biomarkers include increased serum levels of glycan-specific IgG antibodies that predict progression to end-stage kidney disease or death, elevated serum levels of galactose-deficient IgA1 correlated with risk of progressive kidney deterioration, FHR proteins associated with more rapid decline in kidney function, and selected urine microRNAs that potentially may diagnose IgA nephropathy or determine disease severity.

REFERRAL

Patients with suspected IgAN are commonly referred to nephrologists for diagnosis and treatment, typically presenting with gross hematuria and urinalysis with blood and proteinuria.

PEARLS & CONSIDERATIONS

COMMENTS

- Gross hematuria (red urine) is uncommon with intrinsic kidney diseases but is commonly encountered in IgA nephropathy and cyst rupture in autosomal dominant polycystic kidney disease.
- IgA nephropathy is not an entirely benign condition, even when microhematuria is the only clinical presentation. Nearly 40% of patients reach end-stage kidney disease after 20 yr of illness.
- Episodic gross hematuria that occurs during upper respiratory infections is a classic presentation for IgA nephropathy. Angiotensin-converting enzyme inhibitors or ARB is initiated.

BASIC INFORMATION

DEFINITION

IgA vasculitis (IgAV, formerly known as Henoch-Schönlein purpura [HSP]) is a systemic, small-vessel, IgA immune complex–mediated leukocytoclastic vasculitis characterized by a tetrad of palpable purpura, colicky abdominal pain, renal disease, and arthritis/arthralgias. It may also present with gastrointestinal (GI) bleeding.

SYNONYMS

Henoch-Schönlein purpura
Anaphylactoid purpura
Allergic purpura
HSP

ICD-10CM CODE
D69.0 Allergic purpura

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Annual incidence of 3 to 27 cases/100,000 population in children. Approximately 1/100,000 in adults.
PREVALENCE: Most common vasculitis seen in children and younger age groups; seen in white and Asian populations (primarily from Korea and Japan); 3 to 4 times more commonly than in black patients.
PREDOMINANT SEX AND AGE: Approximately 2:1 male:female ratio. Seen mostly from ages 3 to 12 with peak incidence between 4 and 6 yr, although this disorder can be seen in older adolescents and young adults; 90% of all patients are <10 yr old. Older age prognosticates a worse outcome with malignancy found in some.
PEAK INCIDENCE: Late autumn to early spring, rarely in summer. Seasonal variation is not seen in adults.
GENETICS: Recent studies have identified genetic susceptibility factors, but familial recurrence is very rare. There appears to be a strong genetic predisposition with HLA class 2 region related to HLA-DRB1*01 allele. There may also be protective genetic associations of HLA genes that may reduce the risk of acquiring the disease and explain ethnic differences. The ACE, IL*, and HLA-B*35 genes are associated with worse renal phenotype.
RISK FACTORS: There are no formally identified risk factors; however, viral precipitants have been theorized to trigger onset of the disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Palpable purpura (Fig. E1) of dependent areas, especially lower extremities (palms and soles) and areas subjected to pressure, such as the beltline in adults or buttocks in toddlers. Facial involvement is rare.
- GI symptoms are seen in up to two thirds of patients. Common findings are abdominal pain, nausea, vomiting, diarrhea, cramping, hematochezia, and melena. Complications include GI bleeding (20% to 30%), bowel ischemia, intussusception (1% to 5%), and bowel perforation (<1%). Pancreatitis and acalculous cholecystitis are rare complications.
- Subcutaneous edema.
- Arthralgias and arthritis in 60% to 85%. Typically oligoarticular, affecting lower extremity and large joints. Periarticular swelling and tenderness also noted.
- Renal involvement is seen in as many as 80% of older children, usually within the first month of illness. Fewer than 5% progress to end-stage renal failure, a major cause of morbidity. Renal manifestations may range from isolated hematuria or proteinuria to severe crescentic glomerulonephritis.
- 10% to 20% of male children can present with pain and swelling of the scrotum that can mimic testicular torsion.
- Central nervous system (CNS) involvement is rare, but can manifest as confusion, weakness, visual deficits, or impaired consciousness.

ETIOLOGY

- Presumptive etiology is exposure to a trigger antigen that causes antibody formation.
- Antigen-antibody (immune) complex deposition then occurs in arteriole and capillary walls of skin, renal mesangium, and GI tract. Immunoglobulin A (IgA) deposition is most common.
- Abnormal IgA1 glycosylation is a leading cause of the elevated serum galactose-deficient IgA1 levels seen in the disease.
- Antigen triggers postulated include drugs, foods, immunization, and upper respiratory and other viral illnesses. Group A streptococcal infection is the most common precipitant in children, seen in up to one third of cases. Of childhood cases, 30% to 65% are preceded by an unspecified upper respiratory infection. Various precipitants have been described in case reports including parvovirus B19, *Helicobacter pylori*, and intravesical BCG (used for treatment of bladder cancer), to name a few.
- Case reports have been published describing development of IgA vasculitis after treatment with a variety of medications including immunosuppressive agents (e.g., etanercept, infliximab, adalimumab) and more widely used medications such as vancomycin, pantoprazole, and ibuprofen. There is no correlation between vaccinations and development of IgAV.

DIAGNOSIS

- Diagnosis is generally clinical. Nonthrombocytopenic purpura (see Fig. E2) is essential to the diagnosis. Skin or renal biopsy demonstrating IgA deposition in vessel walls can help narrow the differential diagnosis
- Skin manifestations are most common and primarily affect small superficial vessels. See Box E1 for common clinical manifestations of IgA vasculitis
- Skin biopsy shows leukocytoclastic vasculitis. Renal biopsy shows mesangial IgA deposition

FIG. E1 Palpable purpura in a patient with IgA vasculitis. (From Hoffman R et al [eds]: *Hematology: basic principles and practice,* ed 4, Philadelphia, 2005, Saunders.)

TABLE E1 Laboratory Features of Henoch-Schönlein Purpura/ Immunoglobulin A Vasculitis

Investigations	Possible Findings
Initial Investigations	
Complete blood count	May reveal leukocytosis or anemia
Acute-phase reactions (ESR or CRP)	Normal or elevated
Urinalysis	Normal, hematuria, or proteinuria
Stool guaiac examination	Normal, positive
Secondary Investigations (Indicated According to Clinical Features and Abnormal Results of the Above)	
Urine protein/creatinine	Normal, increased, nephrotic range
Renal functional tests	Normal, elevated creatinine, hypoalbuminemia
Plain abdominal supine radiography and chest radiography	Normal, air leak
Abdominal ultrasonography	Thickened bowel wall, intussusception
Tests for Differential Diagnosis	Diseases to be Differentiated
Blood culture	Specific infections
Imaging procedures and relevant biopsies	To differentiate from PAN
ANCA	ANCA-associated vasculitis
Antinuclear antibodies, anti–double-stranded DNA, complement 3	SLE, hypocomplementemic urticarial vasculitis

ANCA, Antineutrophil cytoplasmic antibody; *CRP,* C-reactive protein; *ESR,* erythrocyte sedimentation rate; *PAN,* polyarteritis nodosa; *SLE,* systemic lupus erythematosus.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

- The presence of two of the following four American College of Rheumatology criteria yields a diagnostic sensitivity of 87.1% and specificity of 87.7%:
  1. Palpable purpura unrelated to thrombocytopenia
  2. Age <20 yr at onset of first symptoms
  3. Bowel angina
  4. Granulocytic infiltration of arteriole or venule walls on biopsy
- In 2010, a European consortium (European League Against Rheumatism/Paediatric Rheumatology International Trials Organisation/Paediatric Rheumatology European Society) published a set of validated diagnostic criteria that showed 100% sensitivity and 87% specificity. Their criteria described purpura or petechiae and one or more of the following:
  1. Abdominal pain
  2. Predominant IgA deposits on histopathology
  3. Arthritis or arthralgia
  4. Renal involvement

DIFFERENTIAL DIAGNOSIS

- Polyarteritis nodosa
- Acute abdomen
- Meningococcemia
- Rocky Mountain spotted fever
- Cryoglobulinemia thrombocytopenic purpura
- Hypersensitivity vasculitis
- Microscopic polyangiitis
- Granulomatosis with polyangiitis (Wegener granulomatosis)

WORKUP

History, physical examination, laboratory testing, skin or renal biopsy

LABORATORY TESTS (TABLE E1)

- Laboratory abnormalities are not specific for IgA vasculitis but may help identify complications and rule out other diseases.
  1. Electrolytes, blood urea nitrogen, and creatinine.
  2. Urinalysis.
  3. Complete blood count.
  4. Prothrombin time, fibrinogen, and fibrin degradation products.
  5. Blood cultures.
  6. Skin or renal biopsy.
- Leukocytosis and eosinophilia may be seen.
- IgA levels are elevated in approximately 50% of patients.
- Glomerulonephritis may be present (microscopic hematuria, proteinuria, and red blood cell casts).
- Pathologic examination may aid diagnosis.
  1. Characteristic skin biopsy findings include hemorrhage below the epidermis, as well as necrotic thickened small vessels with IgA/C3 deposits.
  2. There is no one characteristic renal lesion, although mesangial IgA deposition is often seen.

IMAGING STUDIES

Imaging studies are generally not diagnostic of IgA vasculitis, although certain studies may be useful to narrow the differential diagnosis and/or screen for complications.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Supportive care with pain management, adequate hydration, and nutrition is the primary intervention as up to 94% of cases in children and 87% cases in adults will resolve spontaneously.

ACUTE GENERAL Rx

- Prednisone 1 to 2 mg/kg PO daily for 2 wk is typically given for severe arthritis and/or abdominal pain. An equivalent dose of methylprednisolone can be used with same efficacy.

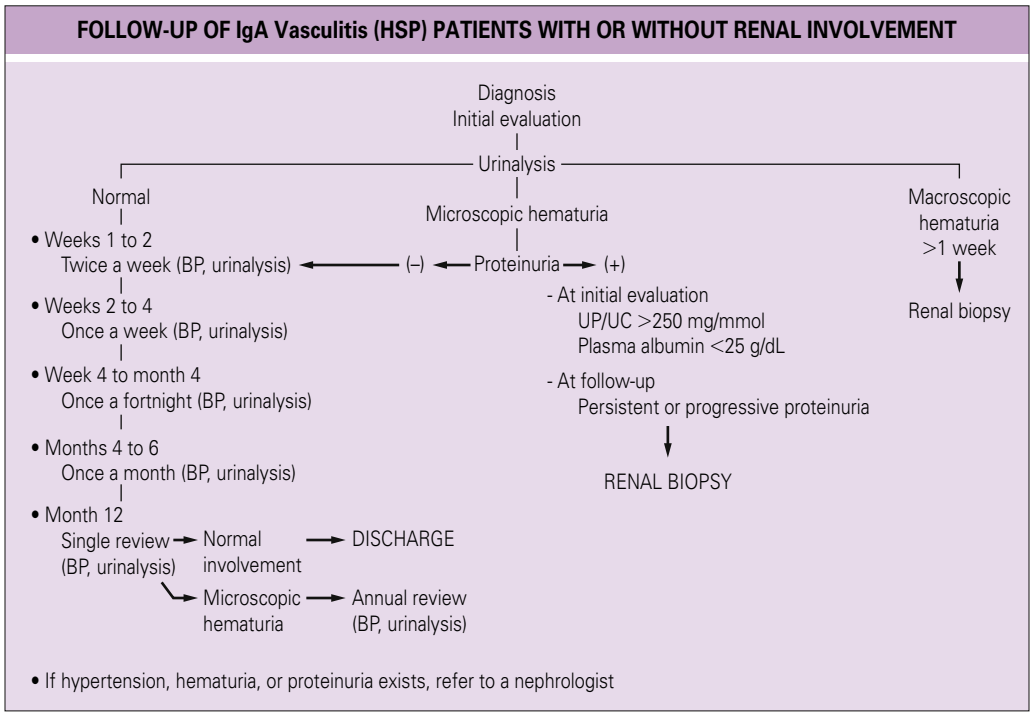

FIG. E3 A practical approach for patients with renal involvement. *BP,* Blood pressure; *UC,* urinary creatinine; *UP,* urinary protein. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

1. A double-blind, randomized, controlled trial (RCT) found that early treatment with prednisone reduced abdominal pain and joint symptoms but did not prevent development of renal disease. It was effective in the treatment of renal disease once it was established.

- Kidney Disease: Improving Global Outcomes (KDIGO) guidelines recommend the same treatment for nephritis related to IgA vasculitis in children and adults.
  1. ACE inhibitor or ARB therapy is suggested for nephritis with persistent proteinuria.
  2. If unsuccessful and GFR >50 ml/min/1.73m^2, treatment similar to that for IgA nephritis with a prolonged (6-mo) glucocorticoid regimen is suggested.
  3. Patients with crescentic glomerulonephritis with deteriorating renal function or nephrotic syndrome related to IgA vasculitis should be treated as if they have crescentic IgA nephritis; such treatment includes corticosteroids and cyclophosphamide.
  4. Recent case series and case reports on a total of 12 patients with biopsy-proven renal involvement who failed steroids +/- immunosuppressives had improvement in kidney function or proteinuria or hematuria with rituximab therapy.
  5. Mycophenolate mofetil has been shown to be useful in glucocorticoid-resistant children with nephrotic range proteinuria, but a recent review that included RCTs did now show strong benefit.
  6. An RCT of 24 children with nephrotic range proteinuria or crescentic HSPN on biopsy, comparing methylprednisolone with cyclosporine, revealed resolution of proteinuria in all 11 patients treated with cyclosporine A within 3 mo vs. 7 of 13 from the methylprednisolone group. The 6 from the methylprednisolone group without resolution were treated with cyclosporine with 5 showing response.
  7. Not all patients with nephritis or nephrotic-range proteinuria respond to these treatments; they eventually may require renal transplantation.
  8. Fig. E3 illustrates follow-up of IgA vasculitis patients with or without renal involvement.
- Severe gastrointestinal involvement (defined by intense pain, GI bleeding, and protein losing enteropathy) improved with intravenous immunoglobulin (IVIG) in eight pediatric patients with IgA vasculitis. IVIG was found to slow or stop effects on eGFR in patients with nephritis. A case series postulated an efficacious addition of plasma exchange to adults with severe renal and extrarenal complications.

CHRONIC Rx

- Even if renal involvement is not present after initial episode, urinalysis and blood pressure should be checked every 2 to 4 wk for first 6 mo to detect development and progression of kidney disease.
- Azathioprine may allow earlier corticosteroid discontinuation in patients with relapsing symptoms of IgA vasculitis.

COMPLEMENTARY & ALTERNATIVE MEDICINE

No complementary or alternative treatment modalities proven to be effective for IgA vasculitis.

DISPOSITION

- Prognosis excellent, with spontaneous recovery within 4 wk in most patients.
- Hospitalization is required for significant GI or renal involvement.
- Increased age of onset generally correlates with morbidity. While end-stage renal disease (ESRD) occurs in 10% to 30% of adult patients with IgA vasculitis at 15 yr, chronic renal insufficiency is the most common long-term morbidity and affects adults more than children.
- Recurrences in up to one third of patients, especially within first 4 to 6 mo after initial episode and most commonly in patients with renal involvement. Recurrences are characteristically less severe than initial episode. For those with relapsing course, immunosuppression may be required depending on the severity of the symptoms.

REFERRAL

Rheumatology, nephrology, or general surgery consultation based on clinical manifestations

PEARLS & CONSIDERATIONS

- Organ systems involved in IgA vasculitis are skin, joints, GI tract, and kidneys.

- Palpable purpura, abdominal pain, arthritis, and renal involvement are common clinical manifestations.
- GI symptoms and arthritis may precede rash. Skin and renal manifestations occur at the same time.
- Most with spontaneous recovery within 4 wk of onset of symptoms.
- End-stage renal disease occurs in only 5% of all patients with IgA vasculitis.

IgG4-Related Disease

BASIC INFORMATION

DEFINITION

IgG4-related disease (IgG4-RD) is a fibroinflammatory condition that can lead to tumefactive and tissue-destructive lesions in nearly every organ (Table 1).

SYNONYMS

Type 1 autoimmune pancreatitis
Mikulicz syndrome

ICD-10CM CODE
D89.89 Other specified disorders involving the immune mechanism

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE AND PREVALENCE: Exact incidence and prevalence are unknown. Most epidemiologic information comes from Japanese studies of autoimmune pancreatitis (AIP).
PREDOMINANT SEX/AGE: Among two study cohorts of 765 patients, mean age of symptom onset was 57.7 and 59.5 yr. There may be a slight predilection for males, about 3:2.
RISK FACTORS: Tobacco, asbestos exposure, atopy, history of malignancy

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with IgG4-RD experience 1.8 yr mean average time to diagnosis.
- Clinical manifestations depend on the distribution of organ involvement, and nearly every organ system may be involved.
- Presentations are subacute and may include constitutional symptoms such as fatigue and weight loss. Arthralgias and enthesopathy may be present; however, frank synovitis is atypical.
- IgG4-RD may involve lacrimal glands, salivary glands, orbits, sinuses, thyroid (Reidel thyroiditis), lymph nodes, aorta and surrounding connective tissue (aortitis, periaortitis), lung (nodules, GGOs, pleural thickening, ILD), kidney (tubulointerstitial nephritis), pancreas (autoimmune pancreatitis), biliary system, skin (cutaneous pseudolymphoma), and lymph nodes.
- Nervous system involvement includes pachymeningitis, hypophysitis, and peripheral nerve inflammation or enlargement.
- IgG4-RD may also cause retroperitoneal fibrosis (RPF), which can manifest with poorly localized pain in back, abdomen, thighs; hydronephrosis and lower extremity edema.

ETIOLOGY

Remains unknown, and disease has only been recognized for a short time. Disease thought to be autoimmune in nature, with CD4+ and T-follicular helper cells playing a role. IgG4 antibodies are not thought to be pathogenic.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Broad, dependent on which organ system is involved:

- Lymphoma, malignancy (i.e., pancreatic cancer)
- Primary sclerosing cholangitis
- Sarcoidosis
- Large-vessel vasculitis, ANCA-associated vasculitis
- Erdheim-Chester disease
- Sjögren syndrome
- Orbital pseudotumor

WORKUP

- Diagnosis based on combination of history, clinical findings, laboratory tests, and radiographic and histopathologic findings.
- Umehara et al proposed diagnostic criteria (see Table 1), which divides IgG4-RD into three categories: definite, probable, and possible. Definitive diagnosis requires fulfillment of clinical, hematologic, and histopathologic criteria. Clinical evidence includes presence of swelling or masses in one or more organ

TABLE 1 Nomenclature of IgG4-Related Disease and Allied Conditions

Organ	Preferred Name	Previously Called
Pancreas	IgG4-related pancreatitis	Type 1 autoimmune pancreatitis
Eye:	IgG4-related ophthalmic disease	Eosinophilic angiocentric fibrosis, multifocal fibrosclerosis
Lacrimal glands	IgG4-related dacryoadenitis	Mikulicz syndrome
Orbital soft tissue	IgG4-related orbital inflammation	
Orbital pseudotumor	IgG4-related orbital pseudotumor	Orbital pseudotumor
Extraocular muscle disease	IgG4-related orbital myositis	
Salivary glands:	IgG4-related sialadenitis	Mikulicz syndrome
Parotid glands	IgG4-related parotitis	Mikulicz syndrome
Submandibular glands	IgG4-related submandibular gland disease	Mikulicz syndrome, Kuttner tumor
Pachymeninges	IgG4-related pachymeningitis	
Hypophysis	IgG4-related hypophysis	Autoimmune hypophysitis
Thyroid	IgG4-related thyroiditis	Riedel thyroiditis, multifocal fibrosclerosis
Aorta or arteries	IgG4-related aortitis or periaortitis	Lymphoplasmacytic aortitis, inflammatory aortic aneurysm
Mediastinum	IgG4-related mediastinitis	Multifocal fibrosclerosis, mediastinal fibrosis
Retroperitoneum	IgG4-related retroperitoneal fibrosis	Multifocal fibrosclerosis, Ormond disease
Mesentery	IgG4-related mesenteritis	
Skin	IgG4-related skin disease	Cutaneous pseudolymphoma
Lymph node	IgG4-related lymphadenopathy	
Bile ducts	IgG4-related sclerosing cholangitis	Sclerosing cholangitis
Gallbladder	IgG4-related cholecystitis	
Liver	IgG4-related hepatopathy	
Lung	IgG4-related lung disease	Eosinophilic angiocentric fibrosis, interstitial pneumonia
Pleura	IgG4-related pleuritis	
Pericardium	IgG4-related pericarditis	
Kidney	IgG4-related kidney disease	
Breast	IgG4-related mastitis	
Prostate	IgG4-related prostatitis	Prostatitis

From Hochberg MC et al: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

BOX 1 Comprehensive Diagnostic Criteria for IgG4-Related Disease

1. Clinical study shows characteristic diffuse or localized swelling or masses in single or multiple organs.
2. Hematologic study shows elevated levels of serum IgG4 (≥135 mg/dl).
3. Histopathologic study shows the following two findings.
   (1) Histologic findings: marked lymphocyte and plasmacyte infiltration and fibrosis.
   (2) IgG4-positive plasma cell infiltration: ratio of IgG4 to IgG positive cells >40% and IgG4-positive plasma cells/hpf >10

Of the above: When (1) + (2) + (3) are fulfilled, it is definite.
When (1) + (3) are fulfilled, it is probable.
When (1) + (2) are fulfilled, it is possible.

However, it is important to differentiate from malignant tumors of each organ (e.g., cancer, lymphoma) and similar diseases (e.g., SS, PSC, Castleman disease, secondary retroperitoneal fibrosis, Wegener granulomatosis with polyangiitis, sarcoidosis, eosinophilic granulomatosis with polyangiitis, etc.) with additional histopathologic examination as much as possible.

Even when a patient cannot be diagnosed with CCD criteria for IgG4-RD, she or he may be diagnosed using organ-specific diagnostic criteria for IgG4-RD.

CCD, Comprehensive clinical diagnostic; *IgG4-RD,* IgG4-related disease; *PSC,* primary sclerosing cholangitis; *SS,* Sjögren syndrome.
From Umehara H et al: Comprehensive diagnostic criteria for IgG4-related disease (IgG4-RD), 2011. *Modern Rheumatol* 22:21-30, 2012. In Hochberg MC et al.: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

systems. A serum IgG4 >135 mg/dl fulfills the hematologic requirement. Histology shows marked lymphocyte and plasmacyte infiltration and fibrosis; it should also show IgG4 positive plasma cell infiltration >40% and more than 10 IgG4 positive plasma cells per hpf.

- An analysis of cross-sectional cohorts recently demonstrated four mutually exclusive groups to which IgG4-RD may be clustered:
  1. Group 1 is characterized by pancreatohepatobiliary disease such as AIP.
  2. Group 2 includes RPF and aortic involvement.
  3. Group 3 encompasses disease limited to the head and neck structures.
  4. Group 4 is characterized by head and neck involvement along with extraglandular, systemic involvement.

LABORATORY TESTS

- Serum IgG4 is neither sensitive nor specific and has been reported as low as 51% in disease population. IgG4 elevation is also seen in vasculitides and malignancies. IgG4 is unreliable as a biomarker because it may remain normal during disease relapse or elevated despite clinical response.
- Measurement of blood plasmablast concentration if available.
- Other laboratory tests may include peripheral eosinophil count, serum IgE, C3, C4, and UA.
- Serologies can be considered, including SSA, SSB, and ANCA.

IMAGING STUDIES

- Imaging frequently reveals organ enlargement and tumefactive lesions in areas involved (Fig. E1 and Fig. E2).
- Storiform (swirling) fibrosis and obliterative phlebitis are characteristic histopathologic lesions. Histology is consistent across organ systems (Fig. E3).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Patients who are asymptomatic or who have limited disease may be approached with expectant management (watchful waiting).

ACUTE GENERAL Rx

- Glucocorticoids are first line for remission induction. Optimal treatment is unknown and approaches are based on small case series. Steroids typically result in symptom improvement within 2 wk and remission within 2 mo.
- Suggested initial doses of prednisone include 0.6 mg/kg/day and/or prednisone 40 mg/day for 4 wk with taper over 3 to 6 mo.
- Urgent therapy is recommended when there is serious organ involvement such as aortitis, retroperitoneal fibrosis, proximal biliary strictures, tubulointerstitial nephritis, pachymeningitis, pancreatic enlargement, and pericarditis.

CHRONIC Rx

Not all patients require steroid-sparing agents; however, azathioprine, methotrexate, mycophenolate mofetil, 6-mercaptopurine, tacrolimus, cyclophosphamide, and rituximab have been used. Rituximab (1000 mg at day 1, 15) has been shown to be effective even without concomitant glucocorticoid therapy in a prospective study.

REFERRAL

- Rheumatology
- Gastroenterology or to specialty with suspected organ involved

PEARLS & CONSIDERATIONS

- Challenges to recognizing the IgG4-RD include failure to consider the diagnosis.
- IgG4-RD may affect nearly every organ and/or anatomic site.
- IgG4-RD may mimic malignancy, infections or other inflammatory and vasculitic conditions.

Immune Thrombocytopenic Purpura ALG PTG

BASIC INFORMATION

DEFINITION

Immune thrombocytopenic purpura (ITP) is an autoimmune disorder in which antibody-coated or immune complex-coated platelets are destroyed prematurely, producing defects in cellular immunity that result in peripheral thrombocytopenia. In primary ITP, the thrombocytopenia is isolated, whereas in secondary ITP, the condition is associated with other disorders (e.g., systemic lupus erythematosus [SLE], HIV, chronic lymphocytic leukemia [CLL], lymphomas).

SYNONYM

ITP

ICD-10CM CODE
D69.3 Immune thrombocytopenic purpura

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Primary ITP occurs in 10 in 100,000 adults and 5 in 100,000 children.
PREVALENCE: Five to 10 cases per 100,000 persons.
PREDOMINANT SEX: 72% of patients >10 yr are female; among children, males are more commonly affected.
PREDOMINANT AGE: Children ages 1 to 6 yr and young women (70% are <40 yr). New onset of ITP after age 60 yr is uncommon; comprehensive workup for secondary ITP may be required.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The presentation of ITP is different in children and adults:

- Children generally present with sudden onset of bruising and petechiae from severe thrombocytopenia.
- In adults, the presentation is insidious; a history of prolonged purpura may be present; many patients are diagnosed incidentally on the basis of automated laboratory tests that now routinely include platelet counts.
- The physical examination may be entirely normal.
- Patients with severe thrombocytopenia may have petechiae, purpura, epistaxis, or heme-positive stool from gastrointestinal bleeding. Life-threatening bleeding is uncommon and generally confined to patients with platelets <10,000/mm^3.
- Splenomegaly is unusual; its presence should alert to the possibility of other etiologies of thrombocytopenia.
- The presence of dysmorphic features (skeletal anomalies, auditory abnormalities) may indicate a congenital disorder as the cause of the thrombocytopenia.

ETIOLOGY

Increased platelet destruction is caused by autoantibody targets to platelet-membrane antigens, in particular, antibodies against platelet GPIIb/IIIa or GPIb/IX. The spleen has a major role in ITP by producing autoantibodies in the white pulp and removing autoantibody-coated platelets in the red pulp. Production of antibodies could be triggered either by immunogenicity of membrane glycoproteins (GPs) on the platelet surface or by external factors such as infections or medications.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Falsely low platelet count due to aggregation (resulting from EDTA-dependent or cold-dependent agglutinins). Platelet count is corrected by using heparin or citrate anticoagulated tube
- Viral infections (e.g., HIV, hepatitis C, mononucleosis, rubella)
- Drugs commonly implicated are quinidine, heparin, antibiotics (linezolid, vancomycin, sulfonamides, rifampin), platelet inhibitors (tirofiban, abciximab, eptifibatide), cimetidine, NSAIDs, thiazide diuretics, antirheumatic agents (gold salts, penicillamine), and many chemotherapeutic agents (cyclosporine, fludarabine, carboplatin, oxaliplatin)
- Hypersplenism resulting from liver disease
- Myelodysplastic and lymphoproliferative disorders
- Pregnancy, hypothyroidism
- SLE, thrombotic thrombocytopenic purpura (TTP), hemolytic-uremic syndrome
- Congenital thrombocytopenia (e.g., Fanconi syndrome, May-Hegglin anomaly, Bernard-Soulier syndrome)

LABORATORY TESTS

- Complete blood count, platelet count, and peripheral smear: Platelets are decreased. The peripheral smear should show large platelets and no schistocytes (Fig. E1). Red blood cells and white blood cells have a normal morphology. Unless the patient has been bleeding, the hemoglobin level and leukocyte count should be normal.
- Additional tests may be ordered to exclude other causes of the thrombocytopenia when clinically indicated (e.g., HIV, antinuclear antibody [ANA], thyroid-stimulating hormone [TSH] [hypothyroidism and hyperthyroidism can cause thrombocytopenia], liver enzymes, Hep C ab).
- Direct assay of platelet-bound antibodies has an estimated positive predictive value of only 80% to 83%. A negative test cannot be used to rule out the diagnosis.
- Bone marrow aspiration and biopsy are recommended in adults older than 60 yr if there is evidence of immature cells on peripheral smear or persistent neutropenia.

IMAGING STUDIES

CT scan of abdomen/pelvis in patients with splenomegaly to exclude other disorders causing thrombocytopenia

TREATMENT

NONPHARMACOLOGIC THERAPY

- Minimize activity to prevent injury or bruising (e.g., contact sports should be avoided).
- Stop any potentially offending drugs (see "Etiology"). Avoid medications that increase the risk of bleeding (e.g., aspirin and other NSAIDs).

ACUTE GENERAL Rx

- Treatment varies with the platelet count, patient's age, and bleeding status. For newly diagnosed patients with minimal bleeding treatment consists of corticosteroids vs. observation when platelet counts are <30,000 mm^3 and hospital admission when platelet counts are <20,000 mm^3 (Fig. 2).
- Outpatient observation and frequent monitoring of platelet count are needed in asymptomatic established ITP patients with platelet counts >20,000/mm^3.
- Oral prednisone: 1 mg/kg/day in a tapering course for 4 to 6 wk is the most common initial regimen. Prolonged (>6 wk) courses of prednisone are not recommended. Response rates range from 50% to 75%, and most responses occur within the first 3 wk.
- IV methylprednisolone: 30 mg/kg/day (maximum dose of 1 g/day for 2 or 3 days) infused over 20 to 30 min plus IV immunoglobulin (1 g/kg/day for 2 or 3 days).
- Pulsed-dose oral dexamethasone: Given at a dose of 40 mg/day for 4 consecutive days when given for three to four cycles every 4 wk results in a high response rate (80% to 85%) and has been shown to have fewer side effects when compared to longer courses of prednisone. A meta-analysis of nine randomized trials revealed no major increase in efficacy but confirmed less toxicity and faster increases in platelet counts using high-dose dexamethasone.
- Continuation of corticosteroids is limited by long-term complications associated with its use (osteoporosis, weight gain, opportunistic infections, emotional lability).
- Infusion of platelets should only be given to patients with life-threatening hemorrhage or those undergoing emergent surgery.
- IV immunoglobulin (typically 1 to 2 g/kg in divided doses) is used in two settings: corticosteroid-refractory patients and pregnant patients. It rapidly increases platelet count in nearly 80% of patients, but its effect is transient.
- Anti-D immunoglobulin, a pooled IgG product derived from the plasma of Rh(D)-negative donors, is also effective. It can be given only to patients who are Rh(D) positive with hemoglobin >8 mg/dl and the usual dose is 50 to 75 mcg/kg.
- Rituximab, a monoclonal antibody directed against the CD20 antigen, is used as a second-line agent. Usual dose is 375 mg/m^2 weekly × 4 wk.
- Splenectomy is considered a subsequent option in case of rituximab failure. Previously, it was considered in adults with platelet count <20,000/mm^3 after 6 wk of medical treatment or after 6 mo if more than 10 to 20 mg of prednisone per day is still required to maintain a platelet count >30,000/mm^3. In children, splenectomy is generally reserved for persistent thrombocytopenia

(>1 yr) and clinically significant bleeding. Appropriate immunizations (pneumococcal vaccine in adults and children, *Haemophilus influenzae* vaccine, meningococcal vaccine in children) should be administered earlier than 2 wk before planned splenectomy. Postsplenectomy vaccinations should be performed in all cases.

- Additional second-line agents are thrombopoietin receptor agonists (TPO-RA), azathioprine, cyclosporin A, cyclophosphamide, danazol, dapsone, mycophenolate mofetil, and *Vinca* alkaloids.
- Romiplostim, a recombinant fusion protein, and the oral TPO-RA eltrombopag are effective in increasing platelet count in adult patients with chronic ITP refractory to corticosteroids and/or splenectomy. American Society of Hematology guidelines, revised in 2011, recommend the use of TPO-RA for adult patients with ITP at risk for bleeding who have a contraindication to splenectomy, or who have not responded to at least one other therapy.

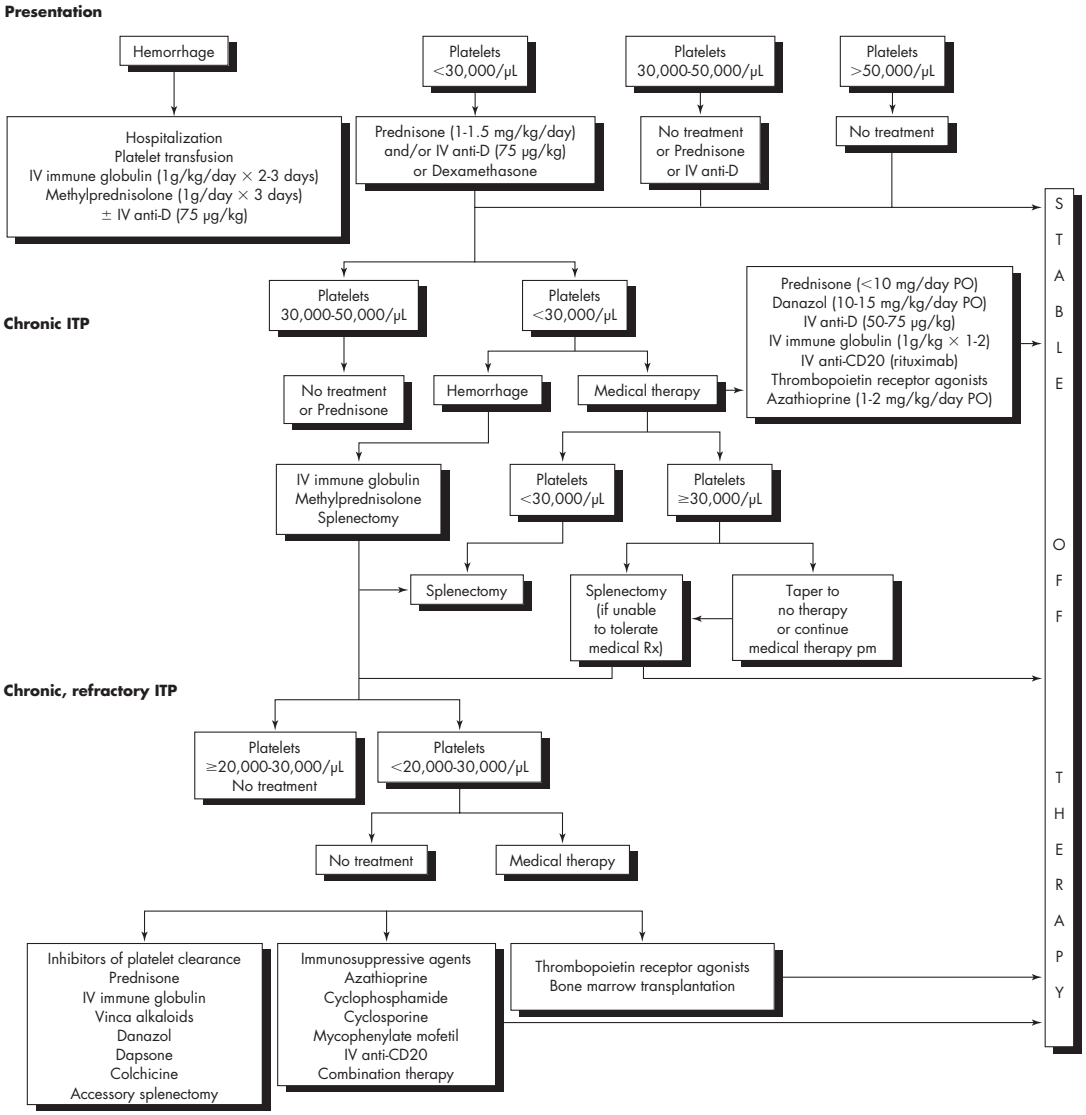

FIG. 2 Treatment algorithm for management of adult-onset immune thrombocytopenic purpura. Some advocate the use of 20,000/mm^3 as a guideline for therapy. The decision to treat patients with platelet counts lower than 50,000/mm^3 is based in part on evidence of bleeding, a history of bleeding, comorbid risk factors, lifestyle, and tolerance of therapy. There is no consensus as to duration of steroid therapy. The use of anti-D as initial therapy is appropriate only for Rh(D)-positive individuals who are not markedly anemic or hemolyzing. The goal of medical therapy is to attain a hemostatic platelet count, generally >20,000 to 30,000/mm^3. The threshold for treatment depends on comorbid risk factors for bleeding and risk of trauma. Higher platelet counts may be appropriate for surgery or after trauma. Medications can be used individually, but combinations of azathioprine and danazol (or corticosteroids) may provide added benefit and allow lower doses to be used. IVIG and anti-D are generally reserved for severe thrombocytopenia unresponsive to oral agents. The decision to proceed to splenectomy depends on intensity of therapy required, tolerance to side effects, risk of surgery, and patient preference. IVIG and/or methylprednisolone may help to increase the platelet count immediately before splenectomy. Laparoscopic and open splenectomy have comparable outcomes. The decision to treat patients who have platelet counts lower than 20,000 to 30,000/mm^3 after splenectomy involves an assessment of the risk of hemorrhage versus the side effects of each form of therapy. *ITP,* Immune thrombocytopenic purpura; *IV,* intravenous; *pm,* precision medicine; *PO,* by mouth; *Rx,* prescription. (Modified from Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Churchill Livingstone.)

- Fostamatinib is an inhibitor of the enzyme spleen tyrosine kinase (Syk). Syk plays an important role in phagocytosis of FcγR-mediated signal transduction and inflammatory propagation. It received FDA approval of chronic ITP in adults who had an insufficient response to previous treatment including corticosteroids, intravenous immunoglobulin (IVIG), splenectomy and/or a TPO-RA. The recommended initial dose is 100 mg oral twice daily. It can be increased to 150 mg twice daily if the platelet count has not responded to at least 50 $\times 10^9/mm^3$ at 1 mo.

PREGNANCY Rx

- No treatment is required when platelet count is >30,000/mm^3 or higher until 36 weeks' gestation, or earlier in case of premature labor.
- Oral corticosteroids and IVIG.
- Refractory ITP may require splenectomy in the second trimester.

DISPOSITION

- More than 80% of children have a complete remission within 8 wk.
- In adults, the course of the disease is chronic; only 5% of adults have spontaneous remission.
- The principal cause of death from ITP is intracranial hemorrhage (1% of children, 5% of adults).

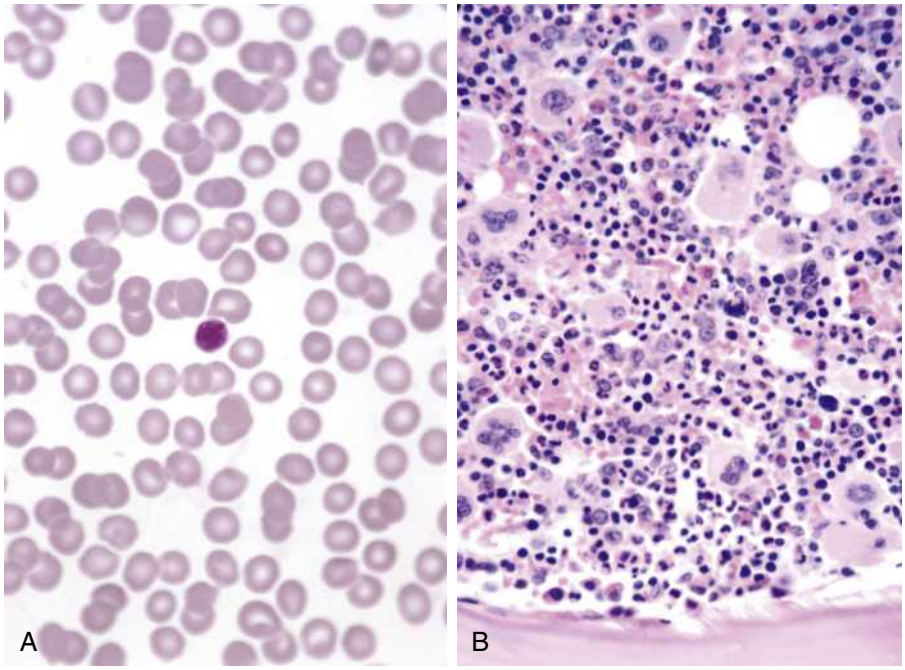

FIG. E1 Immune thrombocytopenic purpura. A, Peripheral blood smear of immune thrombocytopenic purpura. A single large platelet is seen at the center. Large platelets reflect early release from the bone marrow. **B,** The bone marrow trephine biopsy section contains increased numbers of megakaryocytes. (From Jaffe ES et al: *Hematopathology,* Philadelphia, 2011, WB Saunders.)

BASIC INFORMATION

DEFINITION

Impetigo is a highly contagious superficial skin infection generally caused by *Staphylococcus aureus* and/or *Streptococcus* spp.

Common presentations are bullous impetigo (generally caused by staphylococcal disease) and nonbullous impetigo (from streptococcal infection and possible staphylococcal infection); the bullous form is caused by an epidermolytic toxin produced at the site of infection.

SYNONYMS

Impetigo vulgaris
Pyoderma
Impetigo contagiosa
Bullous impetigo

ICD-10CM CODES

L01.00 Impetigo, unspecified
L01.01 Nonbullous impetigo
L01.02 Bockhart impetigo
L01.03 Bullous impetigo
L01.09 Other impetigo

EPIDEMIOLOGY & DEMOGRAPHICS

- Impetigo is the most common bacterial skin infection in children 2 to 5 yr of age. Bullous impetigo accounts for 30% of cases and nonbullous for 70% of cases. Impetigo is most common in temperate zones, mostly during the summer in hot, humid weather. Common sources for children are dirty fingers, pets, and other children in school or day care centers. Impetigo often complicates insect bites, pediculosis, scabies, eczema, and poison ivy.
- Bullous impetigo is most common in infants and children. The nonbullous form is most common in children ages 2 to 5 yr with poor hygiene in warm climates.
- The overall incidence of acute nephritis with impetigo varies between 2% and 5%.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Nonbullous impetigo begins as a single red macule or papule that quickly becomes a vesicle. Rupture of the vesicle produces an erosion of which the contents dry to form honey-colored crusts. Multiple lesions with golden yellow crusts (Fig. E1) and weeping areas are often found on the skin around the nose, mouth, and limbs.
- Bullous impetigo is manifested by the presence of vesicles that enlarge rapidly to form bullae with contents that vary from clear to cloudy. There is subsequent collapse of the center of the bullae (Fig. E2); the peripheral areas may retain fluid, and a honey-colored crust may appear in the center (Fig. E3). As the lesions enlarge and become contiguous with the others, a scaling border replaces the fluid-filled rim; there is minimal erythema surrounding the lesions.
- Regional lymphadenopathy is most common with nonbullous impetigo.
- Constitutional symptoms are generally absent.

ETIOLOGY

- *S. aureus* coagulase positive is the dominant microorganism (50% to 70% of cases).
- *S. pyogenes* (group A β-hemolytic streptococci): M-T serotypes of this organism associated with acute nephritis are 2, 49, 55, 57, and 60. Group B streptococci are associated with newborn impetigo.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Atopic dermatitis
- Herpes simplex infection
- Ecthyma
- Folliculitis
- Dermatitis herpetiformis
- Insect bites
- Scabies, pediculosis
- Tinea corporis, cutaneous candidiasis
- Pemphigus vulgaris and bullous pemphigoid
- Chickenpox
- Thermal burns
- Contact dermatitis
- Stevens-Johnson syndrome, Sweet syndrome

WORKUP

Diagnosis is clinical.

LABORATORY TESTS

- Generally not necessary
- Gram stain and culture and sensitivity to confirm the diagnosis when the clinical presentation is unclear
- Sedimentation rate parallel to activity of the disease

FIG. E1 Nonbullous (crusted) impetigo. Erythematous papules with honey yellow–colored crusting. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

FIG. E2 Bullous impetigo. Thin-walled vesicles and shallow erosions with peripheral collarettes and mild crusting on the buttock and posterior thigh. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

FIG. E3 Bullous impetigo. Multiple tender, erythematous patches with a peripheral collarette, representing remnants of the blister roof. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

- Increased anti-DNAse B and antihyaluronidase
- Urinalysis revealing hematuria with erythrocyte casts and proteinuria in patients with acute nephritis (most frequently occurring in children between ages 2 and 4 yr in the southern part of the U.S.)
- If recurrent staphylococcal impetigo develops, a culture of the anterior nares should be done to rule out a carrier state

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Remove crusts by soaking with wet cloth compresses (crusts block the penetration of antibacterial creams).

GENERAL Rx

- Treatment consists of topical or oral antibotics that are active against both *S. aureus* and β-hemolytic streptococci.
- Application of 2% mupirocin ointment tid for 10 days or retapamulin 1% applied bid for 5 days to the affected area or until all lesions have cleared.
- Ozenoxacin is a topical nonfluorinated quinolone antibiotic recently FDA-approved for treatment of impetigo in patients 2 mo old. Cost is a limiting factor.
- Oral antibiotics are used in severe cases: Commonly used agents are dicloxacillin 250 mg qid for 7 to 10 days, cephalexin 250 mg qid for 7 to 10 days, azithromycin 500 mg on day 1, 250 mg on days 2 through 5, amoxicillin/clavulanate 500 mg q8h.
- Impetigo can be prevented by prompt application of mupirocin or triple-antibiotic ointment (bacitracin, Polysporin, and neomycin) to sites of skin trauma.
- Patients who are carriers of *S. aureus* in their nares should be treated with mupirocin ointment applied to their nares bid for 5 days or a 10-day course of rifampin, 600 mg/day, combined with dicloxacillin (for methicillin-sensitive *Staphylococcus aureus* [MSSA]) or trimethoprim-sulfamethoxazole [TMP-SMX] (for methicillin-resistant *Staphylococcus aureus* [MRSA]).
- Fingernails should be kept short, and patients should be advised not to scratch any lesions to avoid spread of infection.

DISPOSITION

Most cases of impetigo resolve promptly with appropriate treatment. Both bullous and nonbullous forms of impetigo heal without scarring.

REFERRAL

Nephrology referral in patients with acute nephritis

PEARLS & CONSIDERATIONS

COMMENTS

- Patients should be instructed on use of antibacterial soaps and avoidance of sharing of towels and washcloths because impetigo is extremely contagious.
- Children attending day care should be removed until 48 to 72 hr after initiation of antibiotic treatment.
- Bullous impetigo may be an early manifestation of HIV infection.

Inclusion Body Myositis

BASIC INFORMATION

DEFINITION

Inclusion body myositis (IBM) is the most common acquired idiopathic myopathy with onset after the age of 50. The idiopathic inflammatory myopathies include polymyositis (PM), dermatomyositis (DM), autoimmune necrotizing myopathy, and inclusion body myositis. They are associated with inflammatory involvement of muscle fibers and recurrent weakness. Although IBM is classified among the inflammatory myopathies, its underlying pathophysiology has not yet been delineated, and antiinflammatory medications do not improve weakness.

SYNONYM

IBM

ICD-10CM CODE
G72.41 Inclusion body myositis [IBM]

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 0.22 to 0.79 cases/100,000 persons; uncommon in Asians and African Americans
PREVALENCE: 0.5 to 7.1 cases/100,000 persons
PREDOMINANT SEX: Male:female ratio: 1.3:1
PREDOMINANT AGE: 87% older than 50 yr; mean age of 60 yr
PEAK INCIDENCE: Seventh decade
RISK FACTORS: None known
GENETICS: Less than 10% of cases familial

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Insidious onset of slowly progressive proximal leg and distal arm weakness.
- Time to diagnosis from symptom onset often lags by yrs to a decade. Most patients report a history of preexisting weakness averaging 5 to 7 yr.
- Functional loss of strength in the legs most often precedes arm weakness.
- The cardinal clinical features include early weakness and atrophy of quadriceps muscles (difficulty climbing stairs, rising from chairs, and getting out of cars) along with wrist and finger flexor muscles (difficulty grasping, opening jars, and turning doorknobs). Ankle dorsiflexion weakness may also be prominent leading to foot drop and tripping.
- When examining strength, side-to-side asymmetries are seen in one or more muscle groups in the majority of patients. This stands in contrast to the symmetrical, proximal involvement of polymyositis and most muscular dystrophies.
- Dysphagia and/or mild facial weakness are present in about one third to one half of cases. Dysphagia may be the presenting symptom.
- Although sensory symptoms are usually lacking, one third have evidence of peripheral neuropathy on physical examination and/or electrodiagnostic testing.
- 10% to 15% of patients have concomitant autoimmune disorders such as systemic lupus erythematosus, Sjögren syndrome, scleroderma, sarcoidosis, or thrombocytopenia. However, unlike polymyositis and dermatomyositis, IBM does not portend an increased risk of heart disease, lung disease, or cancer.

ETIOLOGY

The pathogenesis of IBM is not known. Inflammatory, degenerative, viral, and prion etiologies have been postulated, but none substantiated.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Polymyositis (Table E1)
- Dermatomyositis
- Amyotrophic lateral sclerosis
- Late-onset muscular dystrophies
- Acid maltase deficiency

WORKUP

- Thorough neurologic examination with emphasis on the motor exam.
- Nerve conduction studies should be performed to exclude other causes and EMG to document a myopathy.
- The diagnosis of definite IBM requires the following features on muscle biopsy (Fig. E1): (1) Inflammation, (2) inflammatory cells invading healthy muscle fibers, (3) vacuoles, and (4) amyloid deposits by Congo red staining, TDP-43 sarcoplasmic staining, or tubulofilaments on electron microscopy.

LABORATORY TESTS

- Creatine kinase level (mildly elevated early in disease but less than 10× normal levels; creatine kinase levels may normalize as the disease progresses).
- Complete blood count and coagulation studies should be drawn in anticipation of the muscle biopsy.

IMAGING STUDIES

MRI may reveal atrophy and signal abnormalities in volar forearm muscle groups and quadriceps atrophy with relative preservation of the rectus femoris muscle.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Physical therapy and occupational therapy with the use of assistive mobility devices such as canes, walkers, and wheelchairs are the mainstay of therapy.
- Occasionally knee orthoses or ankle-foot orthoses may improve and prolong ambulation.

ACUTE GENERAL Rx

None

CHRONIC Rx

- Experts have not found clinically significant improvement in functional strength with any pharmacologic therapy. Clinical trials of corticosteroids, methotrexate, intravenous immunoglobulin, anti-T lymphocyte globulin, etanercept, interferon β-1a, and oxandrolone have all failed to demonstrate functional improvements in limb strength.
- A short, small trial of a home exercise program demonstrated mild improvements in strength.
- IBM is generally refractory to therapy.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Some patients choose to self-treat with creatine supplementation, coenzyme Q10, or lithium. There is no evidence supporting these treatments.

REFERRAL

- Patients with suspected IBM should be referred to a neurologist with subspecialty expertise in neuromuscular medicine.
- Physical therapy and occupational therapy consultations help the patient optimize ambulation and fine motor tasks, respectively.
- Speech therapy consultations can assist with symptomatic dysphagia.

PROGNOSIS

Life expectancy is not significantly altered in this late-onset, slowly progressive disorder. Some patients require wheelchair use 10 to 20 yr after disease onset.

PEARLS & CONSIDERATIONS

COMMENTS

- In contrast to PM and DM, muscle weakness in IBM generally affects both distal and proximal muscles. Although typically symmetric, muscle distribution may be asymmetric.
- A key to diagnosis rests in finding weakness of wrist and/or finger flexors (especially the deep finger flexors at the DIP joints) on examination.

PREVENTION

None known

TABLE E1 Clinical and Laboratory Features of Idiopathic Inflammatory Myopathy Subgroups

Clinical Features	Dermatomyositis	Polymyositis	Inclusion Body Myositis
Age	Children and adults	Adults[a]	Adults >50 yr
Disease onset	Subacute	Subacute	Chronic
Muscle weakness	Proximal	Proximal	Selective pattern[b]
Symmetry	Symmetric	Symmetric	Asymmetric
Systemic features	Yes[c]	Yes[c]	Yes[d]
Skin changes	Yes[e]	No	No
Calcinosis	Yes[f]	Rarely	No
Associated connective tissue disease	Yes[g]	Yes[g]	Yes[h]
Associated malignancy	Yes	Yes	Yes
Laboratory features			
Serum enzymes[i]	Normal to high	Normal to high	Normal to high
Abnormal EMG[j]	Yes	Yes	Yes
Abnormal muscle biopsy	Perifascicular atrophy, capillary depletion, patchy MHC class I expression and microinfarcts	$CD8^+$ T cell invasion of nonnecrotic fibers and MHC class I expression on fibers	$CD8^+$ T cell invasion, MHC expression, vacuolated fibers, and tubulofilamentous inclusions in fibers

$CD8^+$ T cell, cytotoxic T lymphocyte cell; *EMG,* electromyogram; *MHC,* major histocompatibility complex.
[a]Rarely in children.
[b]Early involvement of finger flexor, wrist flexor or wrist extensor weakness, and involvement of quadriceps femoris.
[c]Some patients have dysphagia, synovitis, and interstitial lung disease.
[d]Some patients have dysphagia.
[e]Gottron sign and heliotrope rash.
[f]Especially in children.
[g]Overlap with scleroderma, systemic lupus erythematosus, rheumatoid arthritis, Sjögren syndrome, and mixed connective tissue disease.
[h]Associated with Sjögren syndrome but less frequently associated with other connective tissue diseases.
[i]Serum creatine kinase, aspartate transaminase, lactate dehydrogenase, and aldolase vary from normal to very high levels.
[j]Myopathic motor unit potentials with spontaneous discharges in dermatomyositis, with and without spontaneous discharges in polymyositis, and mixed pattern of short- and long-duration motor unit potentials in inclusion body myositis.
From Firestein GS et al: *Kelley's textbook of rheumatology,* ed 9, Philadelphia, 2013, WB Saunders.

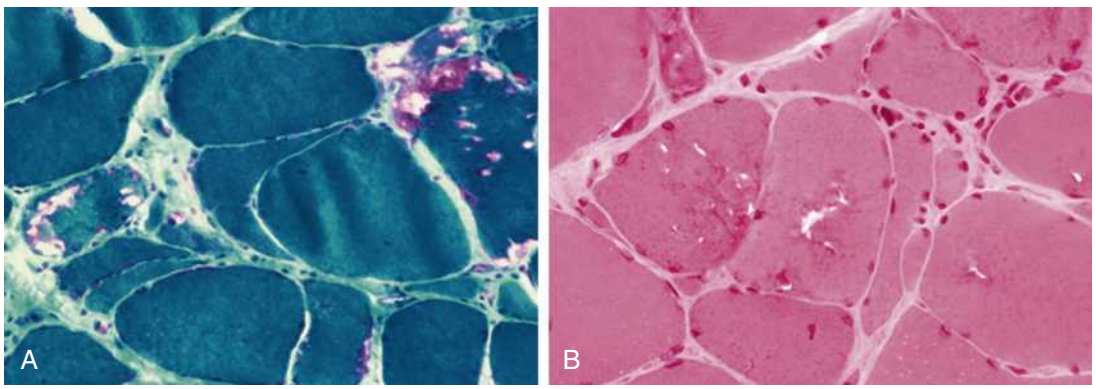

FIG. E1 Trichrome, hematoxylin, and eosin staining of inclusion body myositis biopsy. Note the red-rimmed inclusions **(A)** and marked variation in muscle fiber size **(A** and **B).** (Courtesy Dr. Paul Plotz.)

BASIC INFORMATION

DEFINITION

Fecal incontinence is defined as the involuntary loss of gas or liquid stool (minor incontinence) or the involuntary loss of solid stool (major incontinence).

SYNONYMS

Anal or bowel incontinence
Accidental bowel leakage
Fecal incontinence

ICD-10CM CODES
R15.9 Full incontinence of feces
F98.1 Encopresis not due to a substance or known physiological condition

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Affects 0.5% to 1.5% of the population younger than age 65, but >10% older than 65. More common in institutionalized patients.
PREVALENCE: Varies widely depending on definition used and population studied; often underreported. In community-based studies, ranges from 1% to 24%. Increases with age and BMI in women.
PREDOMINANT SEX AND AGE: Slightly more common in females than males and those of advanced age (older than 65 yr).

RISK FACTORS:
- Cognitive or behavioral dysfunction
- Structural anorectal abnormalities (e.g., rectal prolapse)
- Neurologic disorders, comorbidities (e.g., diabetes mellitus), inflammatory bowel disease (IBD)
- Poor mobility in female gender, advanced age
- Anal sphincter trauma (surgery, obstetrical injury)
- Fecal impaction from constipation or diarrhea

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Inspect perianal area to evaluate for the presence of fecal material, prolapsing hemorrhoids, chemical dermatitis, scars, fistula or rectal prolapse.
- Assess for anocutaneous reflex. This may be elicited by stroking skin in each perianal quadrant (normal response is a brisk anal wink). Absent reflex is suggestive of nerve damage.
- Digital rectal examination to assess for impaction, mass, and resting to squeezing anal tone by asking the patient to bear down. Ask patient to bear down to assess for rectal prolapse or excessive perianal descent.

ETIOLOGY

- Usually multifactorial. Table 1 summarizes the mechanisms, causes, and pathophysiology of fecal incontinence. Common types of anorectal dysfunction causing rectal outlet delay in the elderly are summarized in Table 2
- Overflow due to fecal impaction
- Anal sphincter weakness:
  1. Trauma (e.g., anorectal surgery, childbirth).
  2. Nontraumatic (e.g., neurologic, spinal cord lesions, diabetes, scleroderma).
- Anorectal inflammation:
  1. Radiation, IBD
- CNS disorders (e.g., dementia, multiple sclerosis, stroke)
- Anatomic disturbance of pelvic floor:
  1. Fistula, prolapse
- Idiopathic

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Fecal encopresis
- Irritable bowel syndrome or IBD

WORKUP

- Requires detailed history taking that includes the onset and precipitating events, duration and severity, stool consistency and urgency. Important to evaluate for history of urinary incontinence, anorectal surgery or radiation, neurologic disorders, or prior vaginal deliveries and complete a thorough physical exam. An algorithm for the evaluation and management of patients with fecal incontinence is illustrated in Fig. 1.
- Diagnostic workup may include endoscopy, anorectal manometry, endorectal ultrasound (simple and economical), MRI, defecography,

TABLE 1 Mechanisms, Causes, and Pathophysiology of Fecal Incontinence

Mechanism	Causes	Pathophysiology
Abnormal Anorectal or Pelvic Floor Structures		
Anal sphincter muscles	Hemorrhoidectomy, neuropathy, obstetric injury	Sphincter weakness, loss of sampling reflex
Puborectalis muscle	Aging, excessive perineal descent, trauma	Obtuse anorectal angle, sphincter weakness
Pudendal nerve	Excessive straining, obstetric or surgical injury, perineal descent	Sphincter weakness, sensory loss, impaired reflexes
Nervous system, spinal cord, autonomic nervous system	Avulsion injury, spine surgery, diabetes mellitus, head injury, multiple sclerosis, spinal cord injury, stroke	Loss of sensation, impaired reflexes, secondary myopathy, loss of accommodation
Rectum	Aging, IBD, IBS, prolapse, radiation	Loss of accommodation, loss of sensation, hypersensitivity
Abnormal Anorectal or Pelvic Floor Function		
Impaired anorectal sensation	Autonomic nervous system disorders, central nervous system disorders, obstetric injury	Loss of stool awareness, rectoanal agnosia
Fecal impaction	Dyssynergic defecation	Fecal retention with overflow, impaired sensation
Altered Stool Characteristics		
Increased volume and loose consistency	Drugs, bile salt malabsorption, infection, IBD, IBS, laxatives, metabolic disorders	Diarrhea and urgency, rapid stool transport, impaired accommodation
Hard stools, retention	Drugs, dyssynergia	Fecal retention with overflow
Miscellaneous		
Physical mobility, cognitive function	Aging, dementia, disability	Multifactorial changes
Psychosis	Willful soiling	Multifactorial changes
Drugs*	Anticholinergics Antidepressants Caffeine Laxatives Muscle relaxants	Constipation Altered sensation, constipation Relaxation of sphincter tone Diarrhea Relaxation of sphincter tone
Food intolerance	Fructose, lactose, or sorbitol malabsorption	Diarrhea, flatus

*Pathophysiology is noted for each class of drugs.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

TABLE 2 Types of Anorectal Dysfunction Causing Rectal Outlet Delay in Older People

Pathophysiology	Clinical Picture	
Rectal dysmotility	Reduced rectal motility and contractions Increased rectal compliance Variable degree of rectal dilation Impaired rectal sensation with blunting of urge to pass stool Over time, increasing rectal distention required to reflexively trigger the defecation mechanism	Rectal hard or soft stool retention on digital examination of which patient may be unaware Chronic rectal distention leads to relaxation of the internal sphincter and fecal soiling One postulated cause is diminished parasympathetic outflow as a result of impaired sacral cord function (e.g., from ischemia or spinal stenosis); may also develop through persistent disregard or suppression of the urge to defecate as a result of dementia, depression, immobility, or painful anorectal conditions
Pelvic floor dyssynergia	Paradoxical contraction or failure to relax the pelvic floor and external anal sphincter muscles during defecation Manometric studies show paradoxical increases in anal canal pressure on straining	Severe and long-standing symptoms of rectal outlet delay Parkinson disease More common in younger women
Irritable bowel syndrome	Increased rectal tone and reduced compliance Lower pain threshold on distending the rectum during anorectal function tests	Usually constipation-predominant in older people Rome criteria symptoms: Abdominal distention or pain relieved by defecation, passage of mucus, and feeling of incomplete emptying

From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, 2017, Elsevier.

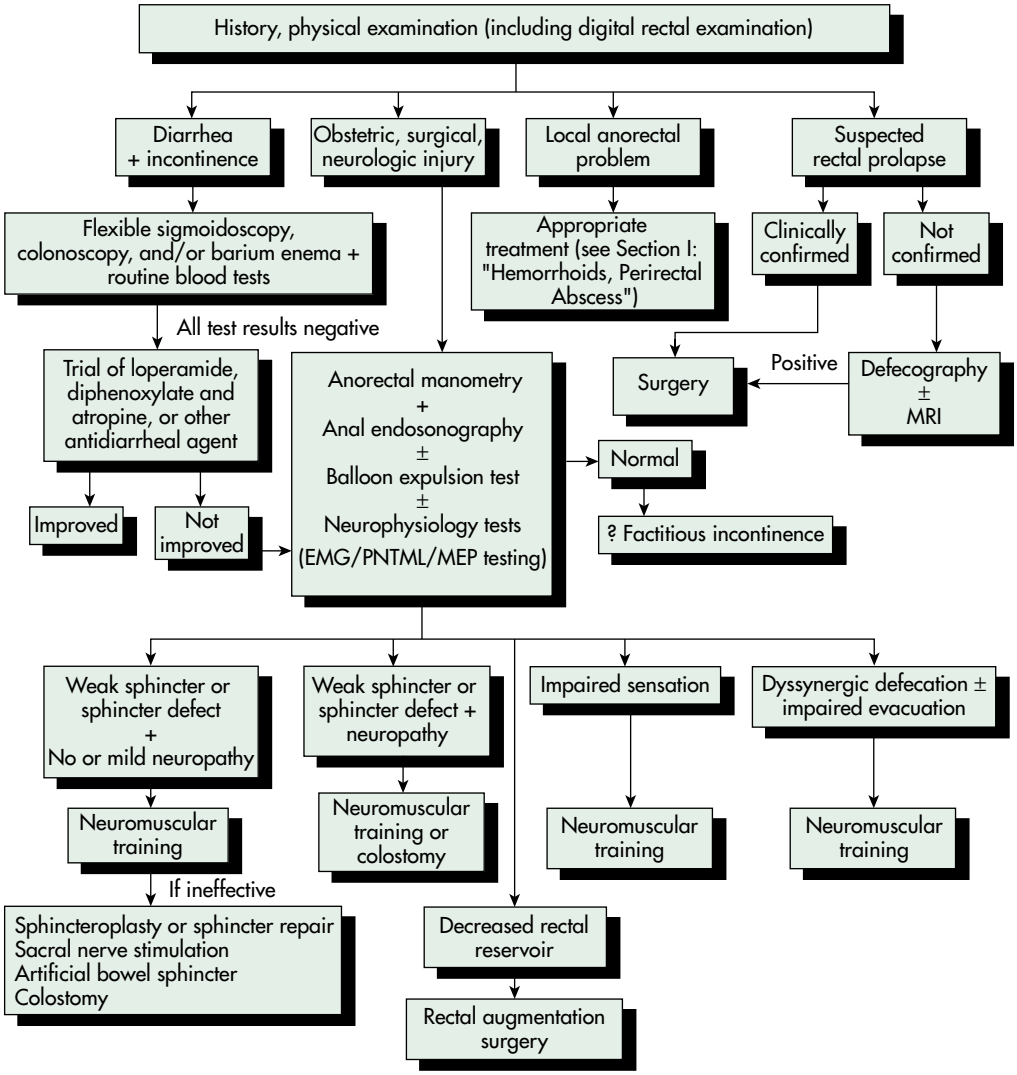

FIG. 1 Algorithm for the evaluation and management of patients with fecal incontinence. *EMG,* Electromyography; *MEP,* motor-evoked potential; *PNTML,* pudendal nerve terminal motor latency. (From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.)

pudendal nerve terminal latency, balloon expulsion test, and anal electromyography (EMG), depending on signs and symptoms. Diagnostic tests for fecal incontinence are summarized in Table 3.

Rx TREATMENT

- Therapy is focused on patient education (Table E4), supportive care, medications, biofeedback, and surgery. Table 5 summarizes bowel preparation in the elderly prior to colonoscopy.
- Medications focus on decreasing stool frequency and improving consistency.
  1. Fiber supplements (e.g., methylcellulose)
  2. Antidiarrheals: Loperamide, diphenoxylate/atropine sulfate, cholestyramine
  3. Topical phenylephrine, oral valproate sodium to increase smooth muscle tone
  4. Injectable anal bulking agent: Dextranomer -hyaluronic acid gel is FDA approved for the treatment of fecal incontinence in adults who fail conservative therapy. Given as four 1-ml injections into the deep submucosal layer of the anal canal. If inadequate response after at least 4 wk, a second course can be attempted.

NONPHARMACOLOGIC THERAPY

- Supportive therapy:
  1. Education, behavioral training, pelvic floor exercises
  2. Dietary modifications (e.g., increased fiber/fluid intake, less caffeine), food diary
  3. Incontinence pads, barrier cream (e.g., zinc oxide)
- Biofeedback therapy
- Electrical stimulation:

TABLE 3 Diagnostic Tests for Fecal Incontinence

Test	Clinical Use: Advantages	Clinical Use: Disadvantages	Quality of Evidence	Comments
Physiologic				
Anorectal manometry	Quantifies EAS and IAS pressures; identifies rectal hyposensitivity, rectal hypersensitivity, impaired rectal compliance, dyssynergic defecation	Lack of standardization	Good	Useful for detecting anal sphincter weakness, altered rectal sensation and accommodation, and dyssynergia
Needle EMG	Quantifies spike potentials and re-innervation pattern indicating neuropathy or myopathy	Invasive, painful; not widely available	Fair	Useful but used largely in research laboratories
Surface EMG	Displays EMG activity; can provide information on normal or weak muscle tone	Inaccurate, frequent artifacts	Fair	Used largely for neuromuscular training
Pudendal nerve terminal motor latency (PNTML)	Measures latency of the terminal portion of the pudendal nerve, simple to perform	Minimally invasive, low sensitivity, interobserver differences	Fair	Conflicting data; correlation with other tests and surgical outcome unclear
Translumbar and transsacral motor-evoked potentials	Quantifies the nerve conduction time of the entire spinoanal and spinorectal pathways; minimally invasive	Lack of standardization, training, controlled studies, and availability	Fair	Promising noninvasive test; more objective and higher yield than PNTML
Colonic transit study with radiopaque markers	Evaluates the presence of fecal retention; inexpensive and widely available	Inconsistent methodology, validity has been questioned	Good	Useful for identifying patients with fecal seepage and older persons with impaction
Balloon expulsion test (BET)	Simple, inexpensive, bedside assessment of ability to expel a simulated stool; identifies dyssynergic defecation	Lack of standardization	Good	Normal BET does not exclude dyssynergia; should be interpreted in the context of other anorectal test results
Imaging				
Anorectal US	Visualizes IAS and EAS defects, thickness, and atrophy and puborectalis muscles	Interobserver bias; scars difficult to identify	Good	Most widely available
Defecography	Detects prolapse, intussusception, obtuse anorectal angle, and pelvic floor weakness, as well as rectoceles and megarectum	Radiation exposure, embarrassment, availability, interobserver bias, inconsistent methodology	Fair	Useful and complementary with other tests
MRI	Simultaneously evaluates global pelvic floor anatomy and dynamic motion; reveals sphincter morphology and pathology outside the anorectum	Expensive, lack of standardization and availability	Fair	Used as an adjunct to other tests
Plain abdominal film	Identifies excessive amount of stool in the colon; simple, inexpensive, widely available	Lack of standardization of interpretation, lack of controlled studies	Poor	Not recommended for routine evaluation but useful in older adults and children with incontinence and fecal impaction
Barium enema	Identifies megacolon, megarectum, stenosis, diverticulosis, extrinsic compression, and intraluminal masses	Lack of standardization, embarrassment, radiation exposure, lack of controlled studies	Poor	Not recommended as part of routine evaluation
Endoscopy				
Flexible sigmoidoscopy and colonoscopy	Directly visualizes the colon to exclude mucosal lesions (e.g., solitary rectal ulcer syndrome, inflammation, malignancy)	Invasive, risks related to procedure (perforation, bleeding) and sedation	Poor	Indicated in patients with unexplained diarrhea and seepage and patients >age 50

EAS, External anal sphincter; *EMG,* electromyography; *IAS,* internal anal sphincter.

Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

TABLE 5 Bowel Preparation in Older People

- Older age, constipation, reported laxative use, tricyclic antidepressants, stroke, diabetes, and dementia are associated with inadequate preparation and taking longer to perform full colonoscopy.
- Even when patients take 75% to 100% of their prescribed treatments, bowel preparation is satisfactory only 50% of the time.

Guidance

- Give regular laxatives (e.g., Movicol 2 sachets daily) and enemas or suppositories for at least 1 wk before the procedure, with a longer run-up period in patients known to have constipation and those with comorbidities such as diabetes.
- Individualize the cathartic regimen (e.g., 1 to 2 L of GoLYTELY daily over 2 to 3 days in those unable to drink 4 L, or use of alternative preparations such as sodium picosulfate).
- Identify potential nonadherence. ("Can the patient drink 4 L of GoLYTELY in 24 hours?")
- Preempt unpleasant side effects. ("Will the patient be able to reach the toilet in time to avoid fecal leakage?")
- Use oral phospho soda with caution as administration in older people increases serum phosphate, even in patients with normal creatinine clearance.
- Consider preprocedure plain abdominal x-ray for evaluation of persistent fecal loading.
- Where possible, give a clear fluid diet before administration of bowel preparation.

From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, 2017, Elsevier.

1. Anal electrodes
2. Sacral nerve stimulation
3. Posterior tibial nerve stimulation

- Surgery:
  1. Anal sphincteroplasty
  2. Implanted devices (e.g., artificial anal sphincter).
  3. Colostomy (if intractable symptoms and/or failed all other therapies)
  4. Miscellaneous: Radiofrequency ablation, anal sling

REFERRAL

Colorectal surgery

PEARLS & CONSIDERATIONS

COMMENTS

The shame, embarrassment, and stigma associated with fecal and urinary incontinence pose significant barriers to seeking professional treatment, resulting in many people suffering from these conditions without help. Therefore, during routine office visits, asking all patients older than 70 about incontinence may be helpful.

PREVENTION

- Reduce constipation and avoid straining during bowel movements.
- Routine episiotomy is the most easily preventable risk factor for fecal incontinence in females.

PATIENT & FAMILY EDUCATION

SUGGESTED READINGS

Available at ExpertConsult.com

AUTHOR: **Fred F. Ferri, MD**

TABLE E4 Patient Education

Toilet Habits and Positioning

- Do not delay having a bowel movement when you feel the urge.
- Put aside a particular time each day (we would advise after breakfast) when you can sit on the toilet without being in a hurry.
- A relaxed attitude to bowel evacuation will help, especially if you have problems with straining or a feeling of anal blockage.
- If straining is a problem, place a footstool under your feet while sitting on the toilet because this increases the ability of your abdominal muscles to help evacuate stool.

Abdominal Massage

- Lie on the bed with pillows under your head and shoulders.
- Bend your knees, and place a pillow underneath them for support.
- Cover your abdomen with a light sheet.
- Massage your abdomen with firm but gentle circular movements, starting at the right side and working across to the left side.
- Continue the massage for about 10 min.
- This massage should be a pleasant experience; if you feel any discomfort, stop.

Diet

- To help prevent constipation, you should eat more of the food from list A and less of the food from list B. Foods from list A tend to make the stool softer and easier to pass because they are high in fiber. Foods from list B tend to make the stool harder because they bind together the contents of the bowel.
  1. List A: Fresh fruit, prunes and other dried fruit, whole meal bread, bran cereals, porridge, salad, cooked vegetables (with skin where possible), beans, lentils
  2. List B: Milk, hard cheese, yogurt, white bread or crackers, refined cereals, cakes, pancakes, noodles, white rice, chocolate, creamed soups
- You should increase your fiber intake gradually because sudden change in fiber content may cause temporary bloating and irregularity. It is important to eat food that contains fiber throughout the day and not just at one meal such as breakfast.
- Increase the amount of fluid you drink gradually, up to 10 glasses a day. Try to drink more water, fruit juices, and carbonated drinks.

Sphincter Strengthening

Learning to Do Your Exercises

- Sit in a comfortable position with your knees slightly apart. Now imagine that you are trying to stop yourself from passing wind from the rectum. To do this, you must squeeze the muscle around the back passage. Try squeezing and lifting that muscle as tightly as you can. You should be able to feel the muscle move. Your buttocks, abdomen, and legs should not move at all. You should be aware of the skin around the back passage tightening and being pulled up and away from your chair. Really try to feel this. You now are exercising your anal sphincter muscles. (You do not need to hold your breath when you tighten the muscles.)

Practicing Your Exercises

- Tighten and pull up the anal sphincter muscles as much as you can. Hold tightened for at least 5 seconds, then relax for at least 10 seconds.
- Repeat the exercise at least 5 times. This will improve the strength of your muscles.
- Next, pull the muscles to about half of their maximum squeeze and see how long you can hold this. Then relax for at least 10 seconds.
- Repeat at least 5 times. This will improve the endurance, or staying power, of your muscles.
- Pull up the muscles as quickly and tightly as you can, relax, then pull up again. See how many times you can do this before you get tired. Try for at least 5 quick pull-ups. Try this quick exercise at least 10 times each day.
- Do all these exercises as hard as you can several times a day. As the muscles get stronger, you will find that you can do more pull-ups each time without getting tired.
- It takes time for exercises to make muscle stronger. You may need to exercise regularly for several mo before the muscles reach their full strength.

Instructions for Using Suppositories

- These may be inserted into your rectum by your nurse or caregiver, or yourself if you are physically able.
- If necessary, first go to the toilet and empty your bowels if you can.
- Wash your hands.
- Remove any foil or wrapping from the suppository.
- Either squat or lie on your side with your lower leg straight and your upper leg bent toward your waist.
- Gently but firmly insert the suppository, narrow end first, into the rectum using a finger. Push far enough (about 1 inch) so that it does not come out again.
- You may find your body wanting to push out the suppository. Close your legs and keep still for a few minutes.
- Try not to empty your bowels for at least 10 to 20 min.

BASIC INFORMATION

DEFINITION

Urinary incontinence is the involuntary loss of urine.

SYNONYMS

Urinary incontinence
UI

ICD-10CM CODES

R32	Unspecified urinary incontinence
N39.3	Stress incontinence (female) (male)
N39.41	Urgency urinary incontinence
N39.46	Mixed incontinence
N39.49	Disorder of urinary system, unspecified
R39.81	Functional urinary incontinence

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE/PREVALENCE: In the general population between the ages of 15 and 64 yr, 1.5% to 5% of men and 25% to 57% of women have urinary incontinence. In the nursing home population, 75% of the population has some degree of incontinence. Nearly 20% of children through the mid-teenage yrs have episodes of urinary incontinence.

CLINICAL, PSYCHOLOGICAL, & SOCIAL IMPACT

Fewer than 50% of women living with incontinence in the U.S. consult health care professionals for care, resulting in significant physical and psychological limitations. Many women choose to turn to home remedies, commercially available absorbent materials, and supportive aids. As the incontinence worsens, many women become depressed, limit social interaction, refrain from sexual intimacy, and become homebound. It is estimated that $19.5 billion in direct costs is spent annually on incontinence in the U.S. Urinary incontinence contributes to approximately 6% of nursing home admissions in the older population, leading to a cost of $3 billion per yr. With aging populations around the world, this cost is dramatically increasing every yr.

The continence mechanisms are complex and include multiple levels of control—central and peripheral nervous systems, detrusor muscle, urethra, and pelvic floor muscle. Normal function depends on multiple levels of control and dysfunction at any of these levels can lead to incontinence.

MAJOR TYPES OF INCONTINENCE (FIG. 1)

- **Stress urinary incontinence (SUI)** (Table E1) is the complaint of involuntary loss of urine with effort or physical exertion (sporting activities), or on sneezing or coughing (any activity that increases intraabdominal pressure). SUI may be demonstrated in the office with a simple cough stress test during examination. The cotton swab test can determine the degree of urethral mobility, which may be helpful in determining which type of surgical procedure to perform, but this test is not useful for diagnosing SUI.
- **Intrinsic sphincter deficiency (ISD)** is the most severe form of SUI and indicates a urethra that cannot remain closed even at rest. Urodynamically, this is diagnosed with a maximal urethral closure pressure <20 cm H_2O and leak point pressure <60 cm H_2O.
- **Urgency urinary incontinence (UUI)** is the complaint of involuntary loss of urine associated with urgency, a sudden compelling desire to pass urine that is difficult to defer. The diagnosis is often made clinically based on patient's report of symptoms but may also be associated with involuntary detrusor contractions on urodynamic investigation. May be idiopathic or neurogenic.
- **Overactive bladder (OAB)** is described as a constellation of symptoms (Figs. E2 and E3) including urgency, with or without urgency urinary incontinence, usually with urinary frequency and nocturia. It should be distinguished from excessive fluid intake and must exclude urinary tract infection. Can occur in up to 27% of men and up to 43% of women.
- **Mixed urinary incontinence** is the complaint of involuntary leakage of urine associated with urgency and also with exertion, effort, sneezing or coughing (see Fig. E4).
- **Overflow incontinence** is the leakage of urine resulting from urinary retention with resultant overflow or spilling of the urine. Causes include hypotonic bladder resulting from age, neurologic conditions such as diabetes or spinal cord injury, prior surgery, drug effects (e.g., intravesical Botox), or fecal impaction. It may also be caused by obstruction at the bladder neck and urethra, such as from prior anti-incontinence surgery, pelvic organ prolapse, urethral stenosis, or detrusor-sphincter dyssynergia.
- **Functional urinary incontinence** is the complaint of involuntary leakage of urine resulting from chronic impairments of physical and/or cognitive functioning. This is a diagnosis of exclusion and may be cured by improving the patient's functional status, treating comorbidities, changing medications, and reducing environmental barriers.
- **Extraurethral urinary incontinence** is leakage that bypasses the urethral meatus (i.e., vesicovaginal fistula or ectopic ureter).

DIAGNOSIS

HISTORY

- Since many women are hesitant to bring up symptoms of incontinence, these symptoms should be elicited through simple screening.
- History of present illness, psychosocial factors, congenital disorders, access issues for the physically challenged, neurologic disorders, and medication use are coexistent disorders that may affect the urinary tract.
- Urinary incontinence may be characterized by frequency of incontinence episodes, severity, and extent of bother.
- Voiding diary to assess total voided volume, frequency of micturition, mean volume voided, largest single volume, diurnal distribution, nature and severity of incontinence.
- Assessments of the severity of symptoms and goals for treatment are important parts of the history.

WORKUP

- General physical examination:
  1. Confounding conditions including mobility issues. Comorbid conditions that can cause or contribute to urinary incontinence in elderly patients are summarized in Table 2. Table 3 describes medications that can cause or contribute to urinary incontinence
  2. Neuromuscular deficits (gait of the patient)
- Pelvic exam:
  1. Concurrent pelvic organ prolapse
  2. Vaginal discharge
  3. Estrogen status
  4. Pelvic floor strength assessment

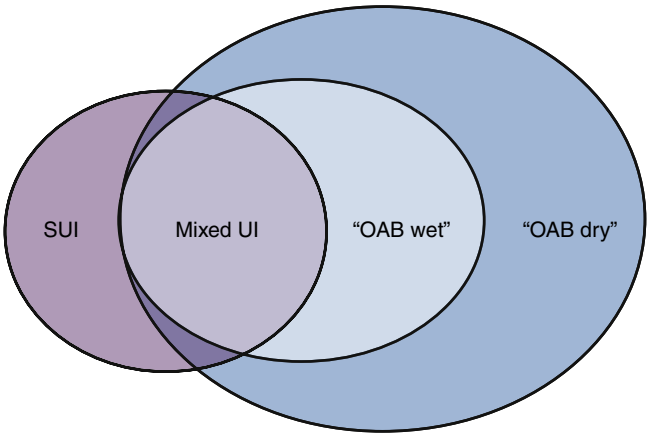

FIG. 1 Incontinence may be stress urinary incontinence *(SUI),* mixed urinary incontinence *(UI),* or urgency urinary incontinence ("overactive bladder *[OAB]* wet"), especially in women. SUI can coexist with "OAB dry," giving rise to mixed symptoms of stress incontinence and urgency. (From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

TABLE 2 Comorbid Conditions that Can Cause or Contribute to Urinary Incontinence in Frail Older Adults

Conditions	Comments	Implications for Management
Comorbid Medical Illnesses		
Diabetes mellitus	Poor control can cause polyuria and precipitate or exacerbate incontinence; also associated with increased likelihood of urgency incontinence and diabetic neuropathic bladder	Better control of diabetes can reduce osmotic diuresis and associated polyuria, improve incontinence
Degenerative joint disease	Can impair mobility and precipitate urgency UI	Optimal pharmacologic and nonpharmacologic pain management can improve mobility, toileting ability
Chronic pulmonary disease	Associated cough can worsen stress UI	Cough suppression can reduce stress incontinence and cough-induced urgency UI
Congestive heart failure Lower extremity venous insufficiency	Increased nighttime urine production can contribute to nocturia and UI	Optimizing pharmacologic management of congestive heart failure, sodium restriction, support stockings, leg elevation, and late afternoon dose of rapid-acting diuretic may reduce nocturnal polyuria, associated nocturia, nighttime UI
Sleep apnea	May increase nighttime urine production by increasing production of atrial natriuretic peptide	Diagnosis and treatment of sleep apnea, usually with continuous positive airway pressure devices, may relieve UI, reduce nocturnal polyuria and associated nocturia
Severe constipation and fecal impaction	Associated with "double" incontinence (urine and fecal)	Appropriate use of stool softeners Adequate fluid intake and exercise Disimpaction if necessary
Neurologic and Psychiatric Conditions		
Stroke	Can precipitate urgency UI and, less often, urinary retention; also impairs mobility	UI after acute stroke often resolves with rehabilitation; persistent UI should be further evaluated. Regular toileting assistance essential for those with persistent mobility impairment
Parkinson disease	Associated with urgency UI; also causes impaired mobility and cognition in late stages	Optimizing management may improve mobility, improve UI Regular toileting assistance essential for those with mobility and cognitive impairment in late stages
Normal-pressure hydrocephalus	Presents with UI, along with gait and cognitive impairments	Patients presenting with all three symptoms should be considered for brain imaging to rule out this condition; may improve with a ventricular-peritoneal shunt
Dementia (Alzheimer, multi-infarct, others)	Associated with urgency UI; impaired cognition and apraxia interfere with toileting and hygiene	Regular toileting assistance essential for those with mobility and cognitive impairment in late stages
Depression	May impair motivation to be continent; may also be a consequence of incontinence	Optimizing pharmacologic and non-pharmacologic management of depression may improve UI Discontinuation or modification of drug regimen
Medications		
Functional Impairments		
Impaired mobility, impaired cognition	Impaired cognition and/or mobility due to a variety of conditions (listed above) and others can interfere with ability to toilet independently and can precipitate UI	Regular toileting assistance essential for those with severe mobility and/or cognitive impairment
Environmental Factors		
Inaccessible toilets Unsafe toilet facilities No contrasting color between toilet and seat Caregivers unavailable for toileting assistance	Frail, functionally impaired persons require accessible and safe toilet facilities and, in many cases, human assistance to be continent	Environmental alterations may be helpful; supportive measures such as pads may be necessary if caregiver assistance not regularly available

UI, Urinary incontinence.
From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

5. Neurologic examination to assess sacral nerves with anal wink and bulbocavernosus reflex

- Rectal examination to assess sphincter tone and stool impaction
- Simple cough stress test
- Urethral hypermobility
- Postvoid residual check with bladder scan or catheter to exclude retention
- 3-day bladder diary to assess frequency, timing, and volume of voids

LABORATORY TESTS

It is important to rule out urinary tract infection and microscopic hematuria with urinalysis and/or culture prior to more invasive testing for other causes for incontinence.

SPECIALIZED STUDIES

- **Urodynamic testing:** Measures different facets of urine storage and evacuation; usually necessary only if basic office evaluation does not elicit the cause of incontinence, if incontinence is persistent despite treatments, or if there are confounding contributors to incontinence including prior surgery
  1. Simple cystometrogram: Graph of bladder and abdominal pressures related to fluid volume during filling/storage/voiding to assess sensation and capacity; also assesses presence of detrusor contractions, whether voluntary or involuntary
  2. Uroflowmetry and pressure-flow studies: Measure the mechanism of bladder emptying and rate of urine flow
  3. Urethral mechanism and pressure studies
  4. Electromyography: Studies the neuromuscular activity of pelvic muscles and striated urethral sphincter during filling and micturition
- **Cystourethroscopy:** Procedure that can be done in the office or the operating room in which an endoscope is inserted into the urethra to view the inside of the bladder and urethra. This procedure is not routinely used

TABLE 3 Medications that Can Cause or Contribute to Urinary Incontinence in Frail Older Adults

Medications	Effects on Continence
α-Adrenergic agonists	Increased smooth muscle tone in urethra and prostatic capsule may precipitate obstruction, urinary retention, related symptoms
α-Adrenergic antagonists	Decreased smooth muscle tone in urethra may precipitate stress urinary incontinence in women
Angiotensin-converting enzyme inhibitors	Cause cough that can exacerbate UI
Anticholinergics	May cause impaired emptying, urinary retention, and constipation, which can contribute to UI; may cause cognitive impairment, reduce effective toileting ability
Calcium channel blockers	May cause impaired emptying, urinary retention, and constipation, which can contribute to UI; may cause dependent edema, which can contribute to nocturnal polyuria
Cholinesterase inhibitors	Increase bladder contractility, may precipitate urgency UI
Diuretics	Cause diuresis and precipitate UI
Lithium	Polyuria due to diabetes insipidus
Opioid analgesics	May cause urinary retention, constipation, confusion, immobility, all of which can contribute to UI
Psychotropic drugs Sedatives Hypnotics Antipsychotics Histamine-1 receptor antagonists	May cause confusion and impaired mobility and precipitate UI; anticholinergic effects; confusion
Selective serotonin reuptake inhibitors	Increase cholinergic transmission, may lead to urinary UI
Others—gabapentin, glitazones, nonsteroidal antiinflammatory drugs	Can cause edema, which can lead to nocturnal polyuria and cause nocturia and nighttime UI

UI, Urinary incontinence.
From Fillit HM: *Brocklehurst's textbook of geriatric medicine and gerontology,* ed 8, Philadelphia, 2017, Elsevier.

to evaluate incontinence unless hematuria is present or prior pelvic surgery is noted on history

IMAGING STUDIES

- These are usually ordered only if history and/or physical findings suggest other, less common causes of incontinence (i.e., genitourinary fistula) or if microscopic hematuria is present.
- Renal ultrasound may be used to assess for hydronephrosis.
- CT urogram may be used to assess upper tract abnormalities, congenital anomalies, genitourinary fistula, and microscopic hematuria etiologies.

Rx TREATMENT

- The recommended approach to urinary incontinence is a stepped care plan first offering noninvasive behavioral modifications such as bladder training, weight loss, and fluid management. Fig. E5 summarizes the diagnosis and treatment of overactive bladder
- **Pelvic floor muscle training,** including Kegel exercises and often augmented with biofeedback or electrical stimulation, is an important component of first-line therapy for stress, urge, and mixed incontinence. Women should perform 45 to 50 exercises per day to achieve good results (60% to 85% reduction in incontinence if biofeedback is also used)
- **Estrogen,** oral or vaginal, increases the concentration of alpha-adrenergic receptors in the urethra and bladder, which improves vascularity and subsequently increases thickness of the urethral epithelium in women with urogenital atrophy
- **Pharmacotherapy** is usually reserved for urgency urinary incontinence:
  1. Antimuscarinic (anticholinergic) medications: Block parasympathetic muscarinic receptors (detrusor M2/M3 receptors) to inhibit involuntary detrusor contractions:
     a. Agents available: Darifenacin, fesoterodine, oxybutynin (available orally and as a transdermal patch), solifenacin, tolterodine, and trospium
     b. Efficacy: Shown to improve symptoms and continence but only modestly compared with placebo
     c. Side effects: High rates of discontinuation due to side effects, most often dry mouth and constipation. May also exacerbate urinary retention, blurred vision, dyspepsia, and impaired cognitive function, with some studies now showing an association with dementia if used for >2 yr; contraindicated in narrow-angle glaucoma
     d. Of note, trospium may have a lower risk of cognitive impairment give the size of the molecule as it is less likely to cross the blood-brain barrier
  2. Beta-agonists: Stimulate β3-adrenergic receptor in the detrusor muscle to cause relaxation and increase bladder capacity
     a. Agent available: Mirabegron
     b. Efficacy: Significant reductions in urgency incontinence in randomized trials
     c. Side effects: Tachycardia, hypertension, headache, and diarrhea (similar to placebo); not recommended in uncontrolled hypertension
  3. OnabotulinumtoxinA (Botox A): Inhibits the presynaptic release of acetylcholine from motor neurons at the neuromuscular junction to paralyze the muscle; given by cystoscopic intravesical injection every 6 to 12 months:
     a. Efficacy: Similar rates of improvement seen when compared with antimuscarinic medications, but more women reporting complete resolution of urgency urinary incontinence with Botox A (35% to 50% reporting "total continence" in clinical trials); third-line treatment due to adverse effects
     b. Adverse effects: Urinary retention or incomplete bladder emptying (5% requiring catheterization) and urinary tract infections (33%)
- **Peripheral tibial nerve stimulation:** 30-minute session of tibial nerve stimulation once per week for 12 weeks followed by a customized maintenance plan to treat OAB. Compared with placebo, pooled success rate was 60% in a guideline published by American Urological Association; fewer adverse events noted when compared with anti-muscarinic medication
- **Sacral neuromodulation:** Stimulation of bladder and pelvic floor nerves to treat OAB, UUI, and idiopathic urinary retention. The mechanism is unknown. The procedure occurs in a two-stage process: first the electrode is placed near S3 to determine if symptoms are improved by 50%; if so, then next the pulse generator is implanted. Evidence suggests 70% of women experience significant improvement in their symptoms with sacral neuromodulation
- **Augmentation cystoplasty:** Older procedure that was used before introduction of sacral neuromodulation in patients with poorly compliant bladders who were at risk for upper tract deterioration, completed by using a gastrointestinal segment
- **Devices:**
  1. Continence pessaries: For women with SUI who wish to defer or avoid surgery; help increase urethral resistance during increased intraabdominal pressure. A large randomized controlled trial demonstrated similar outcomes among women who underwent pessary, behavioral therapy, or a combination of both for incontinence; at 12 months, approximately 50% of women still using the

assigned treatment reported improvement in symptoms
2. Over-the-counter vaginal or urethral inserts: Disposable devices used to support the urethra, especially in women with situational stress incontinence (i.e., only when exercising); however, urethral inserts have been associated with a high rate of urinary tract infection

- **Surgery:** Indicated for women with SUI without symptom control after conservative management or as first-line treatment in appropriately counseled women who decline more conservative treatment:
  1. Synthetic slings are the most common primary surgical treatment for SUI. Cure rates of 62% to 98% have been reported in a recent systematic review:
     a. Transvaginal/retropubic: Trocars are passed through the retropubic space from the midurethra to the abdomen (or vice versa). Short-term cure rates range from 73% to 82% according to a 2009 Cochrane meta-analysis, with de novo urgency in approximately 6% of patients
     b. Transobturator: Trocars are passed from the vagina behind the ischium (or vice versa), with similar cure rates as the retropubic slings
     c. Single-incision slings: Only one vaginal incision is needed beneath the urethra; ends of the sling are secured in the internal obturator muscle
  2. Autologous fascial slings: Usually considered second line after the failure of synthetic slings due to length and morbidity of the operation. Cure rates estimated to be 50% to 75% depending on definition of cure
  3. Cadaveric slings: Usually second line; use has declined more recently due to concerns with early failure and declining success rate over time. Cure rates of 74% at 12 to 23 months and 80% at 48 months or greater
  4. Retropubic urethropexy, i.e., Burch procedure (open abdominal or laparoscopic): A large meta-analysis estimated cure rates to be 82% at 12 to 23 months and 73% at 48 months or longer for open procedures
- **Bulking Agents:** For treatment of stress incontinence, without hypermobility or in poor surgical candidates:
  1. Available agents: Carbon-coated zirconium beads, calcium hydroxyapatite, cross-linked polydimethylsiloxane
  2. Effectiveness: Relatively noninvasive but less effective than surgical intervention; cure rate at 63% to 80% at 1 yr
- Treatment for urinary retention and overflow incontinence focuses on reversal of modifiable factors and drainage of urine from the bladder:
  1. Clean intermittent self-catheterization
  2. Sacral neuromodulation

PEARLS & CONSIDERATIONS

COMMENTS

- Weight loss and exercise are helpful for urinary incontinence in obese women. Overweight and obese women with urinary incontinence also have a high prevalence of monthly fecal incontinence (16% found to be associated with low dietary fiber intake after adjustment for other known risk factors for fecal incontinence)
- Transient causes of urinary incontinence in the elderly are described in Table 4.
- Other forms of incontinence:
  1. Nocturnal enuresis: Loss of urine occurring during sleep; can occur as idiopathic or neurogenic
  2. Postvoid dribble: A postsphincteric collection of urine seen with urethral diverticulum; can be idiopathic
  3. Extraurethral incontinence: Enterovesical, urethral; also known as *fistula*
- Conditions that predispose to surgical failure: Advanced age, prior failed incontinence surgery, concurrent detrusor instability, abnormal perineal electromyography, pelvic radiation
- The Women's Preventive Services Initiative (WPSI) recommends screening women for urinary incontinence annually

TABLE 4 Transient Causes of Urinary Incontinence (DIAPPERS)

D	Delirium/confusional state
I	Infection—urinary (symptomatic)
A	Atrophic urethritis/vaginitis
P	Pharmaceuticals (diuretics, and so on)
P	Psychological, especially depression
E	Endocrine (hypercalcemia, hypokalemia, glycosuria)
R	Restricted mobility
S	Stool impaction

TABLE E1 Surgical Treatment of Stress Incontinence

- Abdominal retropubic urethropexy (suspension)
- Marshall-Marchetti-Krantz
  - Burch operation
- Sling procedure:
  - Pubovaginal (bladder neck) sling
    - Autologous:
      - Rectus abdominis fascia
      - Tensor fascia lata
      - Anterior vaginal wall sling
  - Allograft (cadaveric fascia lata fascia)
  - Xenograft:
    - Porcine dermis
    - Small intestinal submucosa
  - Synthetic mesh (polypropylene)
- Tension-free midurethral sling (polypropylene):
  - Retropubic
  - Transobturator
  - Single incision
- Urethral-bulking agents–
  - Carbon-coated zirconium beads
  - Calcium hydroxyapatite
  - Cross-linked polydimethylsiloxane

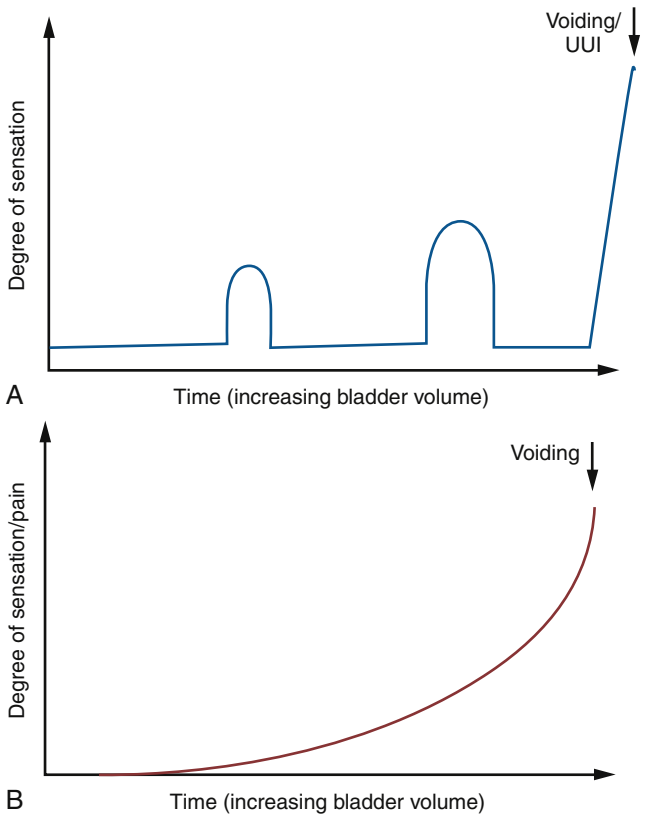

FIG. E2 The differences in the development of bladder sensation in overactive bladder (OAB) and bladder pain syndrome (BPS). A, In OAB, phasic increases in urgency arise and recede as filling progresses, until severe urgency compels the patient to void or an urgency urinary incontinence (UUI) episode sets in. **B,** In BPS, pain increases throughout filling, accelerating as filling progresses. (From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

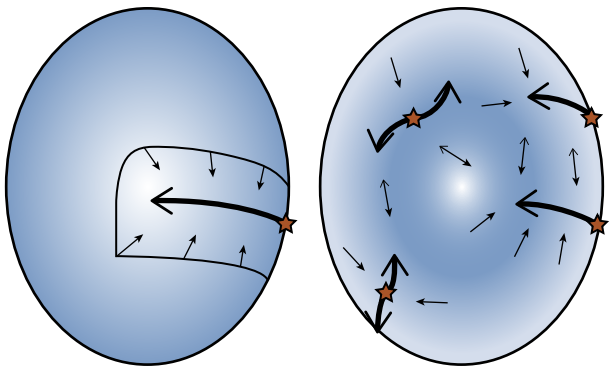

FIG. E3 *Left,* Schematic representation of a whole bladder during urinary storage, illustrating a localized "micromotion" contraction, starting from an initiation point *(star),* and spreading to a limited part of the bladder wall. Such activity is characteristic of the normal isolated bladder in all species tested (including human), and it is associated with only small fluctuations in bladder pressure, presumably because the noncontracting part of the bladder stays relaxed. In the overactive bladder *(right),* multifocal trigger points lead to continuous activity; this enhances the effect on bladder pressure (as the bulk of the bladder is active) and stimulates afferents by the extensive distorting movements. (From Wein AJ et al: *Campbell-Walsh urology,* ed 11, Philadelphia, 2016, Elsevier.)

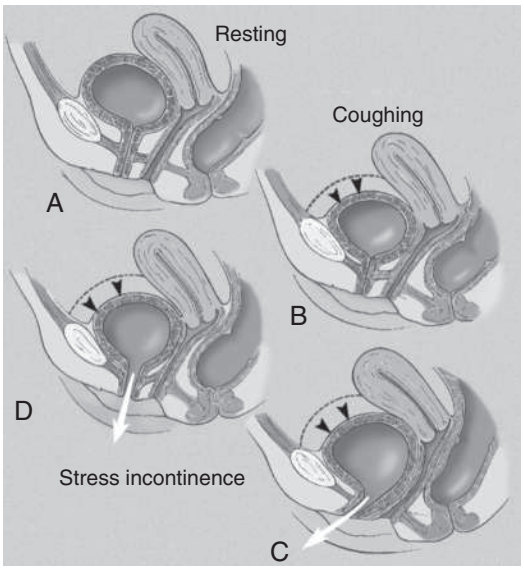

FIG. E4 A, Bladder and urethra in normal position. **B,** Intraabdominal pressure transmitted to the bladder *(arrowheads).* **C,** Bladder and urethra in abnormal position with loss of support (hypermobile). **D,** Loss of urethral closure *(arrow).* (From Lipshultz LI et al: *Urology and the primary care practitioner,* ed 3, Philadelphia, 2008, Elsevier.)

BASIC INFORMATION

DEFINITION

Hypotonia is diminished muscular resistance against passive stretching of the body. Infantile hypotonia refers to hypotonia present in the newborn or infant.

SYNONYM

Floppy infant

ICD-10CM CODES

P94.2	Congenital hypotonia
P94.8	Other disorders of muscle tones of newborn
P94.9	Disorders of muscle tone of newborn, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

The incidence of infantile hypotonia is difficult to assess, as it can be a symptom of multiple disorders. Central causes for hypotonia are approximately four times more common than peripheral causes.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

A detailed history and physical exam are the key tools to localizing the lesion because the cause can be at any level in the neuraxis, providing an extensive differential.

- Assess tone by observing the fully awake child for body movements, body posture, and signs of decreased in utero movements (hip dislocation, arthrogryposis, plagiocephaly, pectus excavatum).
- When supine, hypotonic infants lie with their extremities extended and abducted, termed the frog-leg position.
- When pulled gently by the hands from supine toward sitting position, hypotonic infants have significant head lag and very little resistance to the examiner.
- When held under the arms by the axillae in vertical suspension, hypotonic infants start to slip through the examiner's hands unlike infants with normal tone.
- If held prone with support under the torso in horizontal suspension, hypotonic infants fall limply into an "inverted U"position.
- Signs of hypotonia of central origin include abnormal head shape or size, decreased level of consciousness, dysmorphic features, hyperreflexia, seizures, apnea, or abnormal sleep-wake cycles (Table E1). Signs of hypotonia of peripheral origin (i.e., a lesion in the motor unit) include an alert and profoundly weak infant with hyporeflexia and atrophic muscles. Tongue fasciculations and intention tremor may be seen in anterior horn disease.
- The rest of the neurologic and general exams can provide pertinent clues to specific diagnoses. Cardiac murmurs, skin lesions, hepatosplenomegaly, and other systemic features help narrow the differential.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Common central causes:

- Acquired brain insult
  1. Infection
  2. Hypoxic encephalopathy
  3. Intracranial hemorrhage
- Brain anomalies: Neuromigrational disorders
- Genetic disorders:
  1. Prader-Willi syndrome
  2. Down syndrome
  3. Kabuki syndrome
  4. Williams syndrome
  5. MECP2 duplication syndrome
  6. Fragile X syndrome
  7. Peripheral causes
- Anterior horn cell disease:
  1. Spinal muscular atrophy
  2. Hypoxic injury
  3. Neurogenic arthrogryposis
- Polyneuropathies (motor or sensory):
  1. Hereditary motor-sensory neuropathy
  2. Charcot-Marie-Tooth disease
  3. Congenital hypomyelinating disorder
- Neuromuscular junction disorders:
  1. Infantile botulism
  2. Congenital myasthenia gravis
  3. Transient neonatal myasthenia
- Congenital myopathies:
  1. Central core disease
  2. Nemaline rod myopathy
  3. Fiber-type disproportion myopathy
  4. Multi-minicore disease
  5. Myotubular myopathy
- Muscular dystrophies:
  1. Dystrophinopathies (Becker and Duchenne)
  2. Congenital myotonic dystrophy
  3. Walker-Warburg disease
  4. Fukuyama disease
  5. Muscle-eye-brain disease
- Metabolic disorders:
  1. Acid maltase deficiency (Pompe disease)
  2. Cerebrohepatorenal syndrome (Zellweger)
  3. Cytochrome-c oxidase deficiency
  4. Mitochondrial myopathies
  5. Neonatal adrenoleukodystrophy

TABLE E1 Localizing Examination Findings

Site of Lesion	Strength	Reflexes	Muscle Mass	Fasciculations
Central nervous system	Normal or slightly impaired	Brisk (decreased after acute injury)	Normal	None
Anterior horn cell	Weak	Decreased	Significant atrophy	Prominent (but not in neonatal period)
Peripheral nerve	Weak	Decreased	Atrophy	None
Neuromuscular junction	Weak	Normal	Normal	None
Muscle	Weak	Decreased or absent	Atrophy or pseudohypertrophy	None

LABORATORY TESTS

- Evaluate neonate for sepsis
- Electrolytes including glucose, creatinine, calcium
- Liver function tests
- Ammonia level
- Creatinine kinase level
- Lactate
- Consider TORCH titers
- Karyotype or specific genetic testing
- Serum amino acids
- Urine organic acids
- Acylcarnitine/carnitine panel
- Very long chain fatty acids
- EMG/nerve conduction velocity (NCV)
- Muscle biopsy

IMAGING STUDIES

MRI of brain for structural brain abnormality detection. MRI of spine if spinal morphology needs evaluation.

TREATMENT

Most of these disorders have no specific treatment; supportive care is offered.

However, infantile spinal muscular atrophy (Werdnig-Hoffman disease) now has an FDA-approved therapy, nusinersen, which has been shown to promote achievement of motor milestones and increase event-free survival dramatically compared with placebo. The mechanism of action is an antisense oligonucleotide that promotes production of full-length SMN (survival motor neuron) protein, which is lacking in this disease.

CHRONIC Rx

- Physical therapy, occupational therapy, and other therapies tailored to the patient's specific needs can provide significant improvement in quality of life and ability to function.
- Respiratory illnesses are common in these children, so vaccinations should be kept up to date.

DISPOSITION

- Long-term outcome varies greatly among different diseases.
- As a general rule, a hypotonic infant who requires mechanical ventilation cannot survive extubation (unless the cause is neonatal myasthenia).

AUTHORS: **Saagar N. Patel, MD, Joseph S. Kass, MD, JD, FAAN,** and **Kimberly Jones, MD**

BASIC INFORMATION

DEFINITION

Infertility in a reproductive-age couple is the inability to conceive after unprotected intercourse for ≥1 yr. When a female is greater than 35 yr of age, an evaluation is justified after 6 mo without successful pregnancy. Earlier evaluation at any age is warranted with preexisting symptoms or medical conditions.

SYNONYM

Sterility

ICD-10CM CODES	
N46	Male infertility
N46.8	Other male infertility
N46.9	Male infertility, unspecified
N97.0	Female infertility associated with anovulation
N97.1	Female infertility of tubal origin
N97.2	Female infertility of uterine origin
N97.8	Female infertility of other origin
N97.9	Female infertility, unspecified
O09.00	Supervision of pregnancy with history of infertility, unspecified trimester
O09.01	Supervision of pregnancy with history of infertility, first trimester
O09.02	Supervision of pregnancy with history of infertility, second trimester
O09.03	Supervision of pregnancy with history of infertility, third trimester
Z31.81	Encounter for male factor infertility in female patient

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: One in eight reproductive age couples experience infertility. This prevalence is consistent in all developed countries and there is evidence that it is historically stable.

PREDOMINANT SEX AND AGE: By definition this is a diagnosis of reproductive age couples. Infertility increases with aging in both males and females, but more dramatically in women. Male factor is responsible in ~40% of couples and the female factor is responsible in ~40% of couples. The remainder of the cases are either combined male and female, or unexplained infertility, meaning a clear cause is not identified.

PEAK INCIDENCE: The incidence of infertility increases with age. Subtle decreases in female fertility start as early as age 30. The rate of infertility increases dramatically after age 37, and unassisted pregnancies become extremely uncommon as women reach the mid-40s. There is also a subtle, but still detectable, decrease in male fertility that may start as early as age 30.

RISK FACTORS: Aging is among the most common risk factors, predominantly among females, although there is evidence that aging affects male fertility as well. Women are increasingly deferring pregnancy due to the lack of a partner or career, which is likely associated with increasing prevalence in certain sectors of the population. Tubal factor infertility can be a result of endometriosis, prior tubal surgery, prior ruptured appendix, or sexually transmitted diseases such as chlamydia and gonorrhea. Extremes of weight, particularly obesity, are associated with ovulatory dysfunction. Other causes include polycystic ovarian syndrome (PCOS), hypothalamic dysfunction, thyroid disorders and hyperprolactinemia. Male factor infertility may be idiopathic or due to trauma, infection, varicocele, obstruction, hypothalamic dysfunction, or exposure to environmental toxins. Smoking is the most common lifestyle choice that impairs fertility.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Age
- Previous fertility, particularly if no pregnancy has occurred in another relationship despite absence of contraception
- Absence of secondary sexual characteristics
- Abnormal uterine bleeding or absent menstruation
- Clinical signs of androgen excess: Hirsutism, acne, alopecia
- Abnormal pelvic exam: Enlarged uterus, adnexal masses, pelvic/abdominal tenderness
- History of urological surgery in male or trauma to testes

ETIOLOGY

- Female factor:
  1. Advanced age
  2. Tubal factor: Pelvic inflammatory disease, endometriosis, prior pelvic surgery, history of ruptured appendicitis, prior elective sterilization
  3. Anatomic: Uterine fibroids, polyps, intrauterine adhesions, uterine anomalies
  4. Oligo-/anovulation: Most frequently due to polycystic ovarian syndrome (PCOS), but also due to thyroid abnormalities, hyperprolactinemia, nonclassic congenital adrenal hyperplasia, hypothalamic dysfunction
- Male factor:
  1. Abnormal semen analysis
  2. Elective sterilization
- Idiopathic: Both male and female

DIAGNOSIS

WORKUP

- Confirmation of ovulation: History of regular menstrual cycles, mid-luteal serum progesterone, basal body temperature testing, urinary luteinizing hormone predictor kits
- Complete transvaginal pelvic ultrasound
- Ovarian reserve testing: Anti-müllerian hormone, follicle-stimulating hormone (FSH), and estradiol obtained on cycle day 2 to 4 and antral follicle count
- Fallopian tube evaluation: Hysterosalpingogram (HSG) (Fig. 1)
- Uterine cavity evaluation: HSG, saline infusion sonohysterography, hysteroscopy, or 3D ultrasound of uterus
- Male factor: Semen analysis

LABORATORY TESTS

- Semen analysis, using Kruger strict morphology. Abstain 2 to 5 days prior to test.
- FSH and estradiol collected cycle day 2, 3, or 4 and anti-müllerian hormone as a measure of ovarian reserve.
- Mid-luteal progesterone (ideally 7 days prior to expected menses). Given variability of serum progesterone measurements throughout the day and absence of a reliable threshold, most practitioners use clinical criteria to diagnose ovulatory dysfunction.
- Urinary luteinizing hormone measurement.
- Thyroid-stimulating hormone (TSH).
- In patients with oligo- or anovulation: Prolactin, testosterone, 17-hydroxyprogesterone.

IMAGING STUDIES

- Day 2 or 3 transvaginal pelvic ultrasound to assess uterine or adnexal abnormalities and to count the number of small antral follicles (2 to 9 mm) as a measure of ovarian reserve. If oligo- or anovulatory, to assess for polycystic-appearing ovary
- Hysterosalpingogram (early follicular phase after menses complete but before ovulation, typically between days 5 and 12 of the menstrual cycle)
- Also used for imaging of uterine cavity: Saline infusion sonohysterography, 3D ultrasound of uterus, hysteroscopy

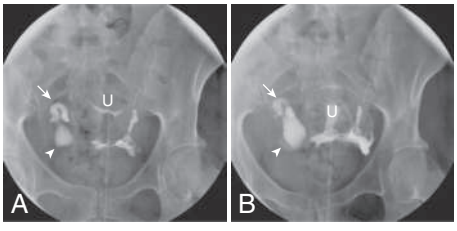

FIG. 1 Hysterosalpingogram spot radiographs early **(A)** and late **(B)** demonstrate a rounded collection of contrast material *(arrowhead)* adjacent to the dilated ampullary portion of the right fallopian tube *(arrow),* caused by peritubal pelvic adhesions related to previous pelvic inflammatory disease. Normal patient left fallopian tube. *U,* Uterus. (From Fielding JR et al: *Gynecologic imaging,* Philadelphia, 2011, WB Saunders.)

Rx TREATMENT

Once the patient presents for evaluation, testing should be completed as quickly as possible, ideally within one menstrual cycle. The couple should follow up with the evaluating provider once all testing is completed and treatment initiated as abnormalities are found.

ACUTE GENERAL Rx

- Fertility preservation options among females are summarized in Table E1. Oligo- or anovulation should be treated with ovulation induction agents, such as clomiphene citrate or aromatase inhibitors. A recent multicenter trial found that aromatase inhibitors achieved higher live birth rates than clomiphene citrate.[1] Historically, clomiphene citrate has been used, but a very well done randomized controlled trial convincingly demonstrated that letrozole is superior. Far less commonly, ovulatory dysfunction is the result of hypothalamic dysfunction. In these patients, once hypothalamic or pituitary abnormalities are excluded with MRI, ovulation can be achieved using injectable gonadotropins.
- Tubal factor infertility may be treated surgically if mild, and if the female patient is young and can afford the time to attempt pregnancy over multiple menstrual cycles. If the patient is older or if the tubal pathology is moderate to severe, in vitro fertilization (IVF) is recommended.
- Uterine anatomic abnormalities such as submucosal fibroids, polyps, intrauterine adhesions, or septate uterus should be corrected if they are identified. Fibroids that do not impact the uterine cavity probably do not interfere with fertility. Removal of intramural or subserosal fibroids is reserved for situations in which these cause excessive vaginal bleeding, pain, or pressure.
- Male infertility: Referral to urologist for complete evaluation. Fertility preservation options for males are summarized in Table E2. If semen analysis is severely abnormal, the following laboratory testing is recommended: Testosterone, FSH, estradiol, luteinizing hormone, TSH and prolactin, karyotype and Y-chromosome microdeletion.
  1. Mild male factor infertility may be treated with intrauterine insemination (IUI), but severe male factor will usually require assisted reproductive technologies (ART) with intracytoplasmic sperm injection (ICSI) in the laboratory, where sperm is injected directly into the oocyte. Some men may require epididymal aspiration or testicular biopsy to obtain sperm for IVF/ICSI. Donor sperm may be necessary in cases of azoospermia due to testicular failure, if male partner has a genetic disorder, or if couple is unable to proceed with IVF/ICSI.
- Unexplained infertility can be treated empirically using superovulation with clomiphene citrate, aromatase inhibitors, or gonadotropins combined with intrauterine insemination with partner's or donor sperm. Most providers recommend using an oral ovulation induction agent with insemination as a first-line superovulatory agent because it is inexpensive. After three to four such cycles, few pregnancies occur and the couple should be advised to become more aggressive. Controversy exists as to whether gonadotropins with insemination or IVF should be used after clomiphene citrate superovulation induction. There is evidence suggesting that moving to IVF after 3 mo of clomiphene citrate and insemination shortens the time interval to achieving pregnancy.[2] A randomized trial in women with unexplained infertility revealed ovarian stimulation with letrozole resulted in a significantly lower frequency of multiple gestation but also a lower frequency of live birth, as compared with gonadotropin but not as compared with clomiphene.
- Donor egg or embryo may be required in cases of premature ovarian insufficiency or due to age factor. Some couples may elect to pursue adoption.
- For LGBT couples, many family building options are available, including IUI or IVF utilizing donor sperm, donor oocytes, and/or gestational carrier, depending on the needs of the couple.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture is widely used by women being treated for infertility. Limited data suggest some benefit, with possible mechanisms of action including increasing blood flow to the uterus and/or ovaries. Despite these studies, it is unproven whether acupuncture definitely improves IVF outcomes. Patients may additionally benefit from the stress relief that acupuncture provides.

DISPOSITION

- Most couples will achieve a pregnancy, provided that they are willing to proceed with treatment including ovulation induction, superovulation, IUI, IVF, or gamete donation.
- Adoption is also a worthwhile and viable possibility for couples unable to conceive.

REFERRAL

Couples should be referred to a reproductive endocrinologist once the complexity of treatment exceeds the comfort level of the provider, whether a family physician, internist, or general gynecologist. Complex ovulation and superovulation induction and ART are best managed by a board-certified reproductive endocrinologist.

[1]Legro RS et al: Letrozole versus clomiphene for infertility in the polycystic ovary syndrome, *N Engl J Med* 371:119-129, 2014.

[2]Reindollar RH et al: A randomized clinical trial to evaluate optimal treatment for unexplained infertility: the fast track and standard treatment (FASTT) trial, *Fertil Steril* 94:888-899, 2010.

PEARLS & CONSIDERATIONS

COMMENTS

- The incidence of heterotopic pregnancy in patients who have undergone ART is relatively common; identification of a patient with ultrasound-proved intrauterine pregnancy who used ART to conceive should NOT necessarily exclude the possibility of an ectopic gestation.
- Single-embryo transfer is becoming more common in IVF cycles to reduce the rate of multiple gestation.
- Preimplantation genetic testing for monogenic/single-gene defects (PGT-M) or preimplantation genetic testing for chromosomal structural rearrangement (PGT-SR) is used in selected IVF cycles when one or both parents has one or more known genetic abnormalities or chromosomal rearrangements to test embryos for these specific genetic abnormalities prior to implantation.
- Preimplantation genetic testing for aneuploidy (PGT-A) is used in IVF cycles to screen embryos for aneuploidy prior to implantation.

PREVENTION

- Techniques that reduce the incidence of pelvic inflammatory disease, such as condom use, can reduce pelvic adhesions that are associated with tubal factor infertility.
- Women should be made aware of the fact that delaying pregnancy into the later reproductive yrs reduces the likelihood for successful pregnancy. Many women are electing to cryopreserve oocytes or embryos for future use.
- Oocyte, embryo, or sperm cryopreservation is recommended for patients undergoing gonadotoxic chemotherapy or radiation treatment as a means of fertility preservation. Ovarian or testicular tissue cryopreservation may also be performed under a research protocol. All patients should be referred to a reproductive endocrinologist before planned treatment to discuss fertility preservation options.

PATIENT & FAMILY EDUCATION

Patient support groups such as *Resolve* (www.resolve.org) are available to help couples during evaluation and treatment of infertility, which can be extraordinarily stressful.

TABLE E1 Fertility Preservation Options Among Females

	Option						
	Embryo Freezing	**Egg Freezing**	**Ovarian Tissue Freezing**	**Radiation Shielding of Gonads**	**Ovarian Transposition**	**Radical Trachelectomy**	**Ovarian Suppression**
Medical status	Standard	Experimental	Experimental	Standard	Standard	Standard	Experimental
Definition	Harvesting eggs, in vitro fertilization, and freezing of embryos for later implantation	Harvesting and freezing of unfertilized eggs	Freezing of ovarian tissue and reimplantation after cancer treatment	Use of shielding to reduce scatter radiation to the reproductive organs	Surgical repositioning of ovaries away from the radiation field	Surgical removal of the cervix with preservation of the uterus	Gonadotropin-releasing hormone analogues or antagonists used to suppress ovaries
Pubertal status	After puberty	After puberty	Before or after puberty	Before or after puberty	Before or after puberty	After puberty	After puberty
Time requirement	10-14 days from menses; outpatient surgical procedure	10-14 days from menses; outpatient surgical procedure	Outpatient surgical procedure	In conjunction with radiation treatments	Outpatient procedure	Inpatient surgical procedure	In conjunction with chemotherapy
Success rates	Approximately 40% per transfer; varies by age and center; thousands of babies born	Approximately 21.6% per embryo transfer; 200+ live births	Case reports of two live births	Only possible with selected radiation fields and anatomy	Approximately 50% because of altered blood flow and scattered radiation	No evidence of higher cancer recurrence rates in appropriate candidates	Unknown; conflicting results reported; larger randomized trials in progress
Cost	Approx. $12,000/cycle; storage fees and pregnancy costs additional	Approx. $12,000/cycle; storage fees and pregnancy costs additional	$12,000 for procedure; storage fees and reimplantation costs additional	Generally included in cost of radiation	Unknown; may be covered by insurance	Generally included in the cost of cancer treatment	$500/mo
Timing	Before or after treatment	Before or after treatment	Before or after treatment	During treatment	Before treatment	During treatment	During treatment
Special considerations	Need partner or donor sperm	May be attractive to single women or those opposed to embryo creation	Not suitable if high risk of ovarian metastases; only preservation option for prepubescent girls	Expertise required; does not protect against effects of chemotherapy	Expertise required	Limited to early-stage cervical cancer; offered at a limited number of centers	Does not protect from radiation effects

Modified from www.livestrong.org/fertility. In Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

TABLE E2 Fertility Preservation Options for Males

	Option				
	Sperm Banking (Masturbation)	**Sperm Banking (Alternative Collection Methods)**	**Radiation Shielding of Gonads**	**Testicular Tissue Freezing**	**Testicular Sperm Extraction**
Medical status	Standard	Experimental	Standard	Experimental	Standard
Definition	Sperm is obtained through masturbation, then frozen	Sperm obtained through testicular extraction or electroejaculation under sedation	Use of shielding to reduce the dose of radiation delivered to the testes	Tissue obtained through biopsy and frozen for future use	Use of biopsy to obtain individual sperm from testicular tissue
Pubertal status	After puberty	After puberty	Before and after puberty	Before and after puberty	After puberty
Time requirement	Outpatient procedure	Outpatient procedures	In conjunction with radiation treatments	Outpatient procedure	Outpatient procedure
Success rates	Generally high; the most established technique for men	If sperm is obtained, similar to standard sperm banking	Possible with select radiation fields and anatomy	No available human success rates	30%-70% in postpubescent patients
Cost	Approximately $1500 for three samples; storage fees average $500/yr	Varies greatly based on collection method	Generally included in the cost of radiation treatments	$500-$2500 for surgery; $300-$1000 for freezing; $500/yr for storage	$4000-$16,000 (in addition to costs for in vitro fertilization)
Timing	Before treatment	Before treatment	During treatment	Before treatment	Before or after treatment
Special considerations	Deposits can be made every 24 hours	Can be considered if male cannot ejaculate	Expertise required; does not protect against effects of chemotherapy	May be only option for prepubescent boys	Center should be able to freeze sperm found at time of biopsy

Modified from www.livestrong.org/fertility. In Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

BASIC INFORMATION

DEFINITION

Inflammatory myopathies are idiopathic diseases of muscle characterized clinically by muscle weakness and pathologically by inflammation and muscle fiber breakdown. The four most common are dermatomyositis (DM), necrotizing autoimmune myositis, polymyositis (PM), and inclusion body myositis (IBM). See separate topics on "Inclusion Body Myositis" and "Necrotizing Autoimmune Myopathy" for details regarding these topics.

SYNONYMS

Immune-mediated myopathies
Idiopathic inflammatory myopathies
Myositis syndromes
Polymyositis
Dermatomyositis
IMM

ICD-10CM CODES

M33.02	Juvenile dermatopolymyositis with myopathy
M33.12	Other dermatopolymyositis with myopathy
M33.20	Polymyositis, organ involvement unspecified
M33.22	Polymyositis with myopathy
M33.90	Dermatopolymyositis, unspecified, organ involvement unspecified
M33.92	Dermatopolymyositis, unspecified with myopathy

EPIDEMIOLOGY & DEMOGRAPHICS

Inflammatory myopathies are the largest group of potentially treatable myopathies in children and adults.

DM:

- Occurs in children and in adults (bimodal age peak).
- Average age at diagnosis is 40 yr in adults. Age range in children: 5 to 14 yr.
- More common in females than in males (2:1).
- Incidence 1:100,000.
- Prevalence 1 to 10 cases/million in adults and 1 to 3.2 cases/million in children.
- Up to one third of patients older than 50 with DM have an associated malignancy.

PM:

- Occurs mostly in adults, very rare in children
- Average age at diagnosis >20 yr
- More common in females
- Least common inflammatory myopathy
- Exact incidence unknown

PHYSICAL FINDINGS & CLINICAL PRESENTATION

DM and PM:

- Most patients have a subacute onset over wks to mos.
- Pattern is typically symmetric proximal muscle weakness involving the proximal limbs (shoulder and pelvic girdles).
- Weakness of neck flexion and extension is common.
- Difficulty getting up from a chair, climbing stairs, reaching for objects above head, or combing hair.
- Distal muscle involvement and ocular involvement are uncommon.
- Sensation is preserved.
- Reflexes may be preserved or diminished.
- Dysphagia and dysphonia result from involvement of striated muscle of the pharynx and proximal esophagus.
- Esophageal dysmotility is common in DM.
- Respiratory failure from associated pulmonary fibrosis.
- Cardiac conduction abnormalities can be seen with DM.
- Systemic autoimmune disease occurs frequently in PM, and rarely in DM.
- Skin findings in DM:
  1. Heliotrope rash on the upper eyelids (Fig. E1)
  2. Erythematous rash on the face
  3. May also involve the back and shoulders (shawl sign), neck and chest (V-shape), knees (Fig. E2), and elbows
  4. Photosensitivity
  5. Gottron papules (violaceous papules overlying dorsal interphalangeal or metacarpophalangeal areas, elbow or knee joints [Fig. E3])
  6. Nail cracking, thickening, and irregularity (Fig. E4) with periungual telangiectasia
  7. Mechanic's hand: Fissured, hyperpigmented, scaly, and hyperkeratotic; also associated with increased risk of interstitial lung disease

ETIOLOGY

DM: Complex, immune-mediated microangiopathy. Adaptive immune response via humorally mediated complement attack

PM: Unknown:

- Cell-mediated immune major histocompatibility-I (MHC-1) process directed against muscle fibers is likely, given biopsy features.
- A viral etiology has been proposed secondary to the presence of autoantibodies to histidyl transferase, anti-Jo-1, and signal recognition particle.

DIAGNOSIS

- The diagnosis of each subtype of inflammatory myopathy is based on clinical history, pattern of muscle involvement, electromyographic findings, muscle biopsy, and presence of certain antibodies.
- Myopathic pattern of muscle weakness.
- Characteristic rash in DM.
- Electromyography (EMG) shows myopathic (small-amplitude, short-duration, polyphasic) motor potentials with early recruitment.
- Majority of patients have "irritable" features (fibrillations and positive sharp waves) on EMG.
- See "Laboratory Tests."
- Biopsy is required for diagnosis and should confirm inflammation before treatment is started. Table 1 describes histologic features of idiopathic inflammatory myopathies. In idiopathic inflammatory myopathies, myopathic features (variation in fiber size, fiber splitting, fatty replacement of muscle tissue, and increased endomysial connective tissue) should be seen in addition to the following:
  1. DM: Perifascicular atrophy, membrane attack complex (MAC) deposition along capillaries
  2. PM: Endomysial infiltrates composed of CD8+ T cells and macrophages invading nonnecrotic muscle fibers that express MHC-I antigen

DIFFERENTIAL DIAGNOSIS

- IBM
- Muscular dystrophies
- Amyloid myoneuropathy
- Amyotrophic lateral sclerosis
- Myasthenia gravis
- Eaton-Lambert syndrome
- Drug-induced myopathies (e.g., quinidine, NSAIDs, penicillamine, HMG-CoA-reductase inhibitors)
- Diabetic amyotrophy
- Guillain-Barré syndrome
- Hyperthyroidism or hypothyroidism
- Lichen planus
- Amyopathic DM (rash without weakness)
- DM sine rash (weakness with characteristic biopsy, but no rash)
- Systemic lupus erythematosus (SLE)
- Contact atopic or seborrheic dermatitis
- Psoriasis

LABORATORY TESTS

- Creatine kinase (CK) is the most sensitive muscle enzyme test for muscle breakdown. It should be checked at onset, and serially monitored several times during treatment.
- CK is typically elevated (5 to 50× normal) in active PM.
- CK may be normal or only slightly elevated in DM.
- Aldolase, aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase, and lactate dehydrogenase (LDH) may be elevated.
- Anti-Jo-1 antibodies are seen in myositis with associated interstitial lung disease but are not specific for either DM or PM.
- Myositis-specific and myositis-associated autoantibodies in adult polymyositis and dermatomyositis and juvenile dermatomyositis are summarized in Table E2.
- DM: Anti-MDA-5, anti-Mi-2, anti-TIF-1, and anti-NXP2 (implicated in cancer-associated dermatomyositis).
- PM: Antisynthetase antibodies (often seen in overlap myositis) associated with interstitial lung disease, arthritis, fever, and "mechanic's hands."
- Electrolytes, thyroid-stimulating hormone (TSH), Ca, and Mg should be evaluated to exclude other causes of weakness.
- Check ECG for cardiac involvement.

IMAGING STUDIES

- Chest x-ray is used to rule out pulmonary involvement. If suspicious for pulmonary interstitial disease, a high-resolution CT scan of the chest may be helpful.
- Radiography is an efficient means of identifying and characterizing soft-tissue calcinosis (Fig. E5).
- Although MRI arguably has greater diagnostic value than electromyography or serum enzyme

TABLE 1 Histologic Features of Idiopathic Inflammatory Myopathies

Feature	Dermatomyositis	Polymyositis	Inclusion Body Myositis
Necrosis of muscle fibers	+	+	+
Variation in fiber diameter	+	+	+
Regeneration of muscle fibers	+	+	+
Proliferation of connective tissue	+	+	+
Infiltration of mononuclear cells*	+	+	+
Perivascular and perimysial inflammation	+	–/+	–/+
Endomysial inflammation	–/+	+	+
Perifascicular atrophy	+	–	–
Abnormally dilated capillaries	+	–/+	–
Reduced capillary density	+	–/+	–
Deposition of complement on vessel walls	+	–/+	–
Microinfarcts	+	–	–
Invasion of non-necrotic fibers by cytotoxic T lymphocytes and macrophages	–	+	+
Expression of major histocompatibility complex class I on muscle fibers	–/+	+	+
Rimmed vacuoles with amyloid deposits and tubulofilaments†	–	–	+
Angulated or atrophic and hypertrophic fibers	–	–	+
Ragged red or cytochrome oxidase–negative fibers	–	–	+

*Inflammation is absent in a small proportion of polymyositis and dermatomyositis biopsies.
†Also seen in chronic neurogenic conditions and distal myopathies.
From Firestein GS et al: *Kelley's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders, Elsevier.

measurements in cases of suspected idiopathic inflammatory myopathy, MRI findings have not been formalized as a diagnostic criterion for idiopathic inflammatory myopathy. The acceptance of MRI as a diagnostic tool in myositis may be inhibited by the high cost and the need for more reliable and validated methods of summarizing the findings of MRI. MRI evaluation before biopsy, however, has become routine at many tertiary care centers. Fascial disease is manifested on MRI by fascial or perifascial hyperintensity on fluid-sensitive sequences. The edema-like signal in the deep subcutis may accompany fasciitis and can indicate associated panniculitis.

- Video fluoroscopy or barium swallow study to look for upper esophageal dysfunction in patients with dysphagia and DM.
- Table E3 summarizes affected organs and their evaluation in inflammatory muscle disease.

Rx TREATMENT

Goal: Maintain function, minimize disease/iatrogenic sequelae

NONPHARMACOLOGIC THERAPY

- Sun-blocking agents with SPF 15 or greater for skin protection in patients with DM
- Physical therapy beneficial for gait training and increasing muscle tone and strength
- Occupational therapy assists with activities of daily living
- Speech therapy to monitor patients with swallowing dysfunction

ACUTE GENERAL Rx

- Corticosteroids are the mainstay of therapy. Start prednisone 1 to 2 mg/kg per day, up to a maximum dose of 100 mg/day. Continue until muscle strength improves or muscle enzymes have normalized for at least 4 wk. Begin tapering by 10 mg/mo until 60 mg/day, then slowly taper by 5 mg/mo. Consider every-other-day prednisone treatment at same dose (may decrease side effects).
- Consider IV immunoglobulin (IVIG) if patient fails to improve on prednisone, or muscle enzymes begin rising when tapering off prednisone. See "Chronic Rx" for specific dosage.
- Hydroxychloroquine can be used to treat the cutaneous lesions of DM.
- A treatment algorithm for adult patients with inflammatory myopathies is illustrated in Fig. 6.

CHRONIC Rx

- Chronic prednisone therapy may be needed for yrs, but other immunosuppressive ("steroid-sparing") agents may be added early to decrease long-term steroid side effects.
- Azathioprine 2 to 3 mg/kg per day tapered to 1 mg/kg per day once steroid is tapered to 15 mg/day. Reduce dosage monthly by 25-mg intervals. Maintenance dosage is 50 mg/day.
- Methotrexate 7.5 to 10 mg PO/wk, increased by 2.5 mg/wk to total of 25 mg/wk; consider IM dosing if PO is ineffective.
- IV immunoglobulin 2 g/kg total dose over 2 to 5 days.
- IV cyclophosphamide 1 g/M^2 monthly for 6 mo is preferred to oral dosing for refractory cases. However, oral dosing of cyclophosphamide is 1 to 3 mg/kg per day PO or 2 to 4 mg/kg per day in conjunction with prednisone.
- Cyclosporine A: Initial dose 2.0 to 2.5 mg/kg bid; long-term maintenance is lowest effective dose.
- Mycophenolate mofetil 500 mg PO bid, titrate to 1500 mg PO bid over 1 to 2 mo.
- Hydroxychloroquine 200 mg PO daily; monitor for visual changes.

DISPOSITION

- 30% to 40% of patients achieve clinical remission with treatment.
- In patients with residual weakness, deficits typically remain stable over long-term follow-up.
- 10% experience recurrent disease.
- Serum CK often returns to normal before symptoms improve.
- During exacerbations, enzymes may rise before clinical symptoms appear.
- Poor prognostic indicators include delay in diagnosis, older age, recalcitrant disease, malignancy, interstitial pulmonary fibrosis, dysphagia, leukocytosis, fever, and anorexia.
- Infection, malignancy, and cardiac and pulmonary dysfunction are the most common causes of death.
- With early treatment, 5- and 8-yr survival rates of 80% and 73%, respectively, have been reported.

REFERRAL

Neurology or rheumatology referral should be made to help establish the diagnosis and implement treatment.

PEARLS & CONSIDERATIONS

- Do not implement treatment before muscle biopsy.
- When assessing response to treatment, clinical muscle strength is more important than muscle enzyme tests.
- The concern for malignancies (ovary, lung, breast, GI) associated with DM is legitimate and merits screening in patients older than age 40 at time of diagnosis and every 2 to 3 yr thereafter.
- No association exists between juvenile DM and malignancy.

- Overlap syndrome refers to patients with DM who also meet criteria for a connective tissue disorder (e.g., rheumatoid arthritis, scleroderma, SLE).
- In any patient taking steroids, closely monitor for:
  1. Diabetes or glucose intolerance (2-hr oral glucose tolerance test)
  2. Osteopenia/osteoporosis (DEXA scan q6mo)
  3. Cataracts (yearly ophthalmologic appointment)
  4. Hypertension
  5. Psychiatric side effects including depression or psychosis
  6. Poor sleep
  7. Peptic ulcer disease (prescribe H_2 antagonist or proton pump inhibitor)
- Clinical and immune response features can be used for categorizing heterogeneous myositis syndromes and mutually exclusive and stable phenotypes and are useful for predicting clinical signs and symptoms, associated environmental and genetic risk factors, and responses to therapy and prognosis.

TABLE E2 Myositis-Specific and Myositis-Associated Autoantibodies in Adult Polymyositis and Dermatomyositis and Juvenile Dermatomyositis

Autoantibody	Autoantigen	Clinical Features
Jo-1, non–Jo-1 (PL7, PL12, EJ, OJ, KS, Tyr, Zo)	Amino-acyl-tRNA synthetase	Fever, Raynaud phenomenon, mechanic's hands, myositis, polyarthritis, ILD
SRP	Signal recognition particle (cytoplasmic protein translocation)	Severe necrotizing myopathy; predominantly PM
Mi-2	Helicase	DM (adult > children); "shawl" sign and other DM rashes
PM-Scl	Nucleolar macromolecular complex	Overlap features of myositis and SSc (or either disease alone); mechanic's hands
U1RNP	Small nuclear ribonucleoprotein	Overlap syndromes (MCTD)
SUMO-1 (small ubiquitin-like modifier 1)	Small ubiquitin-like modifier enzyme (posttranslational modification)	Adult DM, ILD
TIF1-γ (p155/140)	Transcriptional intermediary factor 1-γ (TIF1-γ)	Cancer-associated myositis in adults; >20% frequency in JDM cohorts; severe cutaneous disease in adult DM and JDM
NXP2/MJ (p140)	NXP-2 (SUMO target; possible role in SUMO-mediated transcriptional repression)	20%-25% frequency in JDM cohorts; calcinosis; severe disease (atrophy or contractures)
MDA-5 (cADM-140)	RNA helicase	ADM, ILD; palmar papules and cutaneous ulcerations
PMS1	PMS1 (DNA mismatch repair enzyme)	Myositis (specifics not known)
Ku[1]	70- and 80-kDa nuclear/nucleolar protein complex (DNA break repair and recombination)	UCTD and overlap syndromes (Raynaud phenomenon, ILD, myositis, arthritis)
HMGCR (200/100 kDa)[2,3]	HMG CoA reductase	Necrotizing myopathy

ADM, Amyopathic dermatomyositis; *DM,* dermatomyositis; *HMG CoA,* hydroxymethylglutaryl–coenzyme A; *ILD,* interstitial lung disease; *JDM,* juvenile DM; *MCTD,* mixed connective tissue disease; *PM,* polymyositis; *SSc,* systemic sclerosis; *UCTD,* undifferentiated connective tissue disease.

FIG. E5 Advanced calcinosis. Radiograph of the arm in a girl with juvenile dermatomyositis, showing extensive amorphous and wispy calcification corresponding to subcutaneous calcinosis. Sheetlike calcification outlining muscles corresponds to deep fascial calcification. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Saunders.)

TABLE E3 Affected Organs and Their Evaluation in Inflammatory Muscle Disease

Organ or System	Modalities of Evaluation	Pathologic Processes	Findings
Muscle	Biopsy	Myofiber degeneration and regeneration	Myofiber size variation; vacuolated, necrotic fibers Large central nuclei, basophilic sarcoplasm
		Inflammation	Mononuclear cell infiltration
		Fibrosis	Increased interstitium and fatty replacement of muscle
	EMG	Myofiber destruction	Low-amplitude, short, polyphasic potential; spontaneous fibrillations; irritability
	MRI		
	T1 image	Fibrosis	Atrophy of muscle, scarring
	STIR image	Inflammation	Bright signal in inflamed muscle
Heart	ECG, echo	Myocarditis, fibrosis	Arrhythmias, left ventricular hypertrophy
	Biopsy	Myocarditis, fibrosis	Myofiber size variation, mononuclear cell infiltrates, fibrosis
Lungs	CXR, HRCT	Inflammation, fibrosis	Interstitial markings
	PFTs	Inflammation, fibrosis, restrictive lung disease	Decreased TLV, FVC, and D_{LCO}
	Radionuclide scan	Inflammation, fibrosis	Ventilation–perfusion mismatches
	BAL	Inflammation, fibrosis	Abnormal leukocyte numbers and differentials
	Biopsy	Inflammation, fibrosis	Mononuclear cell infiltration, destruction of alveolar space and fibrosis
Skin	Biopsy	Inflammation	Vacuolization of the basal layer; mononuclear cell infiltration
GI system	Radiographic studies	Inflammation, fibrosis	Reflux and uncoordinated peristalsis

BAL, Bronchoalveolar lavage; *CXR,* chest radiography; *echo,* echocardiography; D_{LCO}, diffusion capacity for carbon monoxide; *ECG,* electrocardiography; *EMG,* electromyography; *FVC,* forced vital capacity; *GI,* gastrointestinal; *HRCT,* high-resolution computed tomography; *MRI,* magnetic resonance imaging; *PFT,* pulmonary function tests; *STIR,* short tau inversion recovery; *TLV,* total lung volume.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

BASIC INFORMATION

DEFINITION

Influenza is an acute febrile illness caused by infection with influenza type A or B virus. Seasonal influenza can include the H1N1 virus. A similar respiratory illness is severe acute respiratory syndrome (SARS) caused by a coronavirus called SARS-associated coronavirus (SARS-CoV). A new novel coronavirus was recognized in two patients in September 2012. This is a very different virus from the SARS agent; the two patients exhibited acute respiratory distress syndrome, renal failure, consumptive coagulopathy, and/or pericarditis. Now called the Middle East respiratory syndrome (MERS-CoV) virus, it has affected more than 2,200 persons in 27 countries since 2012. Patients have fever and pneumonia requiring hospitalization. Transmission spread in 2015 from the Middle East to Korea and China, resulting in more than 185 cases. There were 558 cases in Saudi Arabia from January 2015 through early June 2016, and 75 in 2018. Persons who are immunocompromised or have diabetes, renal failure, or chronic lung disease are thought to be at greater risk of severe illness. Dromedary camels and their milk are documented to harbor MERS-CoV.

Refer to the "Influenza, Avian" topic for more information.

SYNONYMS

Flu
Influenza-like illness (ILI)

ICD-10CM CODES

J10.00	Influenza due to other identified influenza virus with unspecified type of pneumonia
J10.1	Influenza due to other identified influenza virus with other respiratory manifestations
J11.1	Influenza due to unidentified influenza virus with other respiratory manifestations
J12.9	Viral pneumonia, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: Winter outbreaks lasting 5 to 6 wk
PREDOMINANT SEX: Male = female
PREDOMINANT AGE: Attack rates are usually higher among children than adults, although children are less prone to pulmonary complications. The severity of the 2017 to 2018 flu season was described by the Centers for Disease Control and Prevention (CDC) as high for all age groups: children, adults and older adults. Of the 171 reported pediatric deaths in the 2017 to 2018 season, 22% of the vaccine-eligible children had received vaccine.
INCIDENCE (IN U.S.): Annual incidence of influenza-related deaths is between 12,000 and 51,000 deaths/yr.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- "Classic flu" is characterized by abrupt onset of fever, headache, myalgias, anorexia, and malaise after a 1- to 2-day incubation period.
- Clinical syndromes are similar to those produced by other respiratory viruses, including pharyngitis, common colds, tracheobronchitis, bronchiolitis, and croup.
- Respiratory symptoms such as cough, sore throat, and nasal discharge are usually present at the onset of illness, but systemic symptoms predominate.
- Elderly patients may experience fever, weakness, and confusion without any respiratory complaints.
- Acute deterioration to status asthmaticus may occur in patients with asthma.
- Influenza pneumonia: Rapidly progressive cough, dyspnea, and cyanosis may occur after typical flu onset. This may be caused by primary influenza pneumonia or secondary bacterial pneumonia (often pneumococcal or staphylococcal co-infection).
- For influenza A (H3N2v), children younger than 10 yr lack immunity. People ≥65 yr and those with morbid obesity are at high risk.

ETIOLOGY

- Variation in the surface antigens of the influenza virus, hemagglutinin (HA) and neuraminidase (NA), leading to infection with variants to which immunity is inadequate in the population at risk
- Droplet transmission by small-particle aerosols and deposited on the respiratory tract epithelium

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Respiratory syncytial virus, adenovirus, parainfluenza virus infection
- Secondary bacterial pneumonia or mixed bacterial-viral pneumonia

WORKUP

- The accuracy of clinical diagnosis of influenza on the basis of symptoms alone is limited because symptoms from illness caused by other pathogens can overlap considerably with influenza. Diagnostic tests available for influenza include viral cultures, serology, rapid influenza diagnostic tests (RIDTs), reverse transcription-polymerase chain reaction (RT-PCR), and immunofluorescence assays.
- Virus isolation from nasal or throat swab or sputum specimens is the most rapid diagnostic method in the setting of acute illness.
- Specimens are placed into virus transport medium and processed by a reference laboratory.
- For serologic diagnosis:
  1. Paired serum specimens, acute and convalescent, the latter obtained 10 to 20 days later.
  2. Fourfold rises or falls in the titer of antibodies (various techniques) considered diagnostic of recent infection.
  3. Commercial rapid influenza diagnostic tests (RIDTs) are available. They can detect influenza virus antigens within 15 min of testing. Rapid flu test should be collected as early as possible, ideally within 4 days of onset. False-negative results are common during the flu season. A negative test result does NOT exclude diagnosis of influenza.
  4. Commercial RIDTs cannot determine if an H3N2 is a variant virus; when suspect H3N2v virus infection, send nasopharyngeal swab or aspirate in viral transport medium to state public health laboratory for rRT-PCR testing using Centers for Disease Control and Prevention (CDC) FLU rRT-PCR diagnostic panel assay. Novel digital immunoassay (DIAs) and rapid nucleic amplification tests (NAATs) have a markedly higher sensitivity for influenza A and B than traditional RIDTs.

LABORATORY TESTS

Septic syndrome presentation: CBC, ABG analysis, blood cultures

IMAGING STUDIES

- Chest x-ray examination when suspecting viral pneumonia: Peribronchial and patchy interstitial infiltrates in multiple lobes with atelectasis. Table 1 describes x-ray pulmonary findings based on virus type.
- Possible progression to diffuse interstitial pneumonitis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Bed rest
- Hydration

ACUTE GENERAL Rx

- Supportive care: Antipyretics; avoid use of aspirin in children because of the association with Reye syndrome.
- Antibiotics if bacterial pneumonia is proved or suspected.
- Amantadine is NOT recommended due to resistant isolates.
- Neuraminidase inhibitors block release of virions from infected cells, resulting in shortened duration of symptoms and decrease in complications; effective against both influenza A and B, including A (H3N2v) for all hospitalized patients, those with severe and progressive illness, and high-risk patients with suspected or confirmed H3N2v.
  1. Oseltamivir, administered orally:
     a. For treatment, 75 mg PO twice daily for 5 days
     b. For prevention, 75 mg PO once daily for a minimum of 2 wk in an outbreak setting or 7 days after exposure for an adult
  2. Zanamivir, administered via inhaler:
     a. For treatment, 10 mg (2 inhalations of 5 mg each) twice daily for 5 days.

TABLE 1 Pulmonary Radiographic Findings Based on Virus Type

Virus	Centrilobular Nodules	Lobar Ground-Glass	Diffuse Ground-Glass	Thickened Interlobular Septa	Consolidation
Influenza	+++	+++	+		+
Epstein-Barr	+	+	+		+
Cytomegalovirus	++	++	++	+	+
Varicella-zoster	+++	+	+		
Herpes simplex	+	+++	+		+++
Measles	++	+	+		+
Hantavirus			+++	+	++
Adenovirus	++	+			+++

From Weissleder R et al: *Primer of diagnostic imaging,* ed 5, St Louis, 2011, Mosby.

   b. For prevention in households, 10 mg (2 inhalations of 5 mg each) once daily for 7 days. Not recommended in persons with underlying airways disease such as asthma or chronic obstructive pulmonary disease.
   c. Adjust dosing in patients with renal impairment or end-stage renal disease.
3. Baloxavir (Xofluza) was approved by the FDA in 2018 for acute uncomplicated influenza infection in patients ≥ 12 yr of age. Its mechanism of action is through inhibition of an endonuclease involved in viral RNA replication. It is a single dose drug.

- Placebo-controlled studies have suggested that antiviral therapy with any of the previously mentioned agents must ideally be initiated within 1 to 2 days of the onset of symptoms and reduces the duration of illness by ~1 day.
- Oseltamivir resistance developed on therapy in individuals with avian flu (H5N1) in Asia, and this is associated with poor outcome.
- Amantadine and rimantadine resistance are documented for novel (H1N1) influenza and H3N2 influenza virus.
- Systemic corticosteroids should not be routinely administered to patients with suspected or confirmed influenza, including H3N2v virus infection, except for patients on chronic corticosteroid therapy for COPD, asthma.
- Recent trials[1] have shown that in patients hospitalized with severe influenza infection, triple therapy with clarithromycin 500 mg, naproxen 200 mg, and oseltamivir 75 mg bid for 30 days reduced mortality and did not increase complications compared with oseltamivir (75 mg bid for 5 days) alone.

DISPOSITION

Patients are hospitalized if signs of pneumonia are present.

REFERRAL

Infectious disease and/or pulmonary consultation when influenza pneumonia is suspected

[1]Hung IFN et al: Efficacy of clarithromycin-naproxen-oseltamivir combination in the treatment of patients hospitalized for influenza (H3N2) infection: an open-lab, randomized, controlled, phase IIb/III trial, *Chest* 151:1069-1080, 2017.

PEARLS & CONSIDERATIONS

COMMENTS

- Prevention of influenza in patients at high risk is an important goal of primary care.
- Vaccines reduce the risk of infection and the severity of illness.
   1. Antigenic composition of the vaccine is updated annually. The northern hemisphere's 2019 to 2020 season trivalent vaccine includes an A/Brisbane/02/2018 (H1N1) pdm09-like virus (updated), an A/Kansas/14/2017 (H3N2)-like virus (updated), and a B/Colorado/06/2017-like (Victoria lineage) virus.
   2. Quadrivalent vaccines contain these three vaccine viruses, plus a second influenza B vaccine virus strain called B/Phuket/3073/2013-like (Yamagata lineage) virus.
   3. Revaccination is recommended annually before onset of influenza activity in the community, even for those who received the vaccine in the previous season.
   4. Delaying vaccination to ensure persistence of vaccine-induced protection during flu season could result in missed opportunities to vaccinate.
   5. Seasonal influenza vaccine does not provide protection against the influenza A (H3N2v) virus that is associated with agricultural fairs.
   6. Vaccination should be given at the start of the flu season (September-October) for all persons aged ≥6 mo who do not have contraindications. Vaccination is particularly important for persons who are at high risk and their contacts/caregivers. When vaccine supply is limited, vaccination efforts should focus on the following groups:
      a. All children aged 6 mo to 4 yr (59 mo)
      b. People 50 yr and older
      c. Adults and children with chronic cardiac (except hypertension) or pulmonary (including asthma), renal, hepatic, neurologic, hematologic or metabolic disease (including diabetes mellitus)
      d. Immunocompromised patients (including HIV-infected persons or patients immunosuppressed due to medications)
      e. Women who are or will be pregnant during the influenza season
      f. Children aged 6 mo to 18 yr who are receiving long-term aspirin therapy
      g. Residents of nursing homes and other long-term care facilities
      h. American Indians/Alaska Natives
      i. Persons who are morbidly obese (BMI ≥40)
      j. Health care workers (HCWs)
      k. Household contacts and caregivers of persons in the previous groups
   7. Vaccination precautions include:
      a. Guillain-Barré syndrome within 6 wk following a previous dose of influenza vaccine
      b. Moderate or severe acute illness with or without fever
      c. Asthma in persons >5 yr (LAIV4)
      d. Other underlying medical conditions that might predispose to complications after wild-type influenza infection (e.g., chronic pulmonary, cardiovascular [excluding isolated hypertension], renal, hepatic, neurologic, hematologic, or metabolic disorders [underlying diabetes mellitus]) (LAIV4)
   8. Contraindication to receiving vaccine:
      a. Previous severe allergic reaction to influenza vaccine
      b. For LAIV4: Concomitant aspirin- or salicylate-containing therapy in children and adolescents
      c. For LAIV4: Children 2 to 4 yr with asthma Dx in past 12 mo
      d. For LAIV4: Immunocompromised due to any cause including medications or HIV infection
      e. For LAIV4: Close contacts and caregivers of severely immunosuppressed persons who require a protected environment
      f. For LAIV4: Pregnancy
      g. For LAIV4: Received influenza antiviral medication within past 48 hr
   9. Special efforts should be made to vaccinate high-risk patients <65 yr, only 10% to 15% of whom are vaccinated each yr.

TABLE 2 Antiviral Agents for Influenza

	Amantadine	Rimantadine	Zanamivir	Oseltamivir
Protein target	M2	M2	Neuraminidase	Neuraminidase
Activity	A only (H1N1 and H3N2 are resistant)	A only (H1N1 and H3N2 are resistant)	A and B	A and B
Side effects	CNS (13%) GI (3%)	GI (6%)	? Bronchospasm	GI (9%)
Metabolism	None	Multiple (hepatic)	None	Hepatic
Excretion	Renal	Renal, + others	Renal	Renal (tubular secretion)
Drug interactions	Antihistamines, anticholinergics	None	None	Probenecid (increased levels of oseltamivir)
Dose adjustments needed	≥65 yr old CrCl <50 ml/min	≥65 yr old CrCl <10 ml/min	None	CrCl <30 ml/min Severe liver dysfunction
Contraindications	Acute-angle glaucoma	Severe liver dysfunction	Underlying airway disease, asthma	
FDA-Approved Indications				
Therapy	Adults and children ≥1 yr old	Adults only	Adults and children ≥7 yr old	Adults and children ≥1 yr old*
Prophylaxis	Yes	Yes	Adults and children ≥5 yr old	Adults and children ≥13 yr old†

*FDA has authorized treatment of S-OIV (novel H1N1) virus with oseltamivir in children ≥3 mo of age.
†FDA has authorized prophylaxis for S-OIV (novel H1N1) virus with oseltamivir in children ≥1 yr.
CNS, Central nervous system; *CrCl,* creatinine clearance; *FDA,* U.S. Food and Drug Administration; *GI,* gastrointestinal.
From Mandell GL et al: *Principles and practice of infectious diseases,* ed 7, Philadelphia, 2010, Churchill Livingstone.

10. HCW vaccination minimizes transmission to patients and coworkers. Some states mandate vaccination of HCWs; some healthcare facilities and other states require the wearing of face masks by unvaccinated HCWs during the influenza season, particularly when there is widespread flu.
11. Vaccine efficacy varies by age and by type of circulating virus. Efficacy varies each yr and has ranged from 23% to 60% overall; 2018 to 2019 efficacy varied by age group. Even with low efficacy, hospitalizations are reduced.
12. Alternate vaccine formulations:
    a. Intradermal vaccine for injection via a small needle into skin instead of muscle has not been available for every flu season.
    b. The CDC's Advisory Committee on Immunization Practices (ACIP) found no measurable protective benefit from using nasal spray, live-attenuated influenza vaccine (LAIV) during the 2015 to 2016 flu season. ACIP recently reviewed more data and found LAIV4 effective against influenza B and influenza A (H3N2). Effectiveness of the updated LAIV4 against currently circulating influenza A (H1N1) pdm09-like viruses is unknown. ACIP recommends any licensed, age-appropriate influenza vaccine, including LAIV4, for the 2019 to 2020 season.
    c. Give TIV if recipient has egg allergy or asthma or cares for immunosuppressed persons who require a protective environment.
    d. Thimerosal-free vaccine is available.
    e. IIV can be trivalent or quadrivalent, and egg-based or non–egg-based (cell culture or recombinant hemagglutinin).
    f. There is no preference for standard dose IIV or high dose IIV (age 65 or over).
    g. ACIP guidance for egg allergies:
        (1) If a person with egg allergy experiences only hives, then administer trivalent recombinant hemagglutinin influenza vaccine (RIV3) if ages 18 to 49, or IIV and observe for at least 30 min for reaction following vaccine.
        (2) If a person with egg allergy experiences other symptoms such as cardiovascular (e.g., hypotension), respiratory distress (e.g., wheezing), gastrointestinal (e.g., nausea/vomiting), reaction requiring epinephrine or emergency medical attention, administer RIV3 if age 18 to 49, or refer to a physician with expertise in management of allergic conditions.
        (3) If there is no known history of exposure to egg, but the person is suspected of having egg allergy, consult with a physician who has expertise in the management of allergies before vaccinating, or give RIV3 (if ages 18 to 49).
        (4) If person reports past reactions to egg involving symptoms other than urticaria (e.g., angioedema or swelling, respiratory distress, lightheadedness, recurrent emesis) or who required epinephrine or other medical intervention, should be vaccinated in a medical setting with supervision of vaccine administration by health care provider able to recognize and manage severe allergic reactions.

- Storage of vaccines:
    1. Maintain storage temperatures with adequate refrigeration and temperature monitoring.
    2. Do not use beyond expiration date or manufacturer's beyond use date.
    3. Do not access single-dose vial for more than one dose.
- Chemoprophylaxis:
    1. Table 2 describes antiviral agents for influenza. Oseltamivir and zanamivir are recommended in the U.S. during the influenza season. Baloxavir marboxil was recently (2018) FDA approved and may eventually replace the other agents as a preferred drug (single-dose treatment for persons 12 to 65 yr old weighing over 40 kg, low side-effects profile).
    2. Consider (after the current circulating strain of influenza has been shown to be sensitive):
        a. For high-risk patients in whom vaccination is contraindicated
        b. When the available vaccine is known not to include the circulating strain
        c. To provide added protection to immunosuppressed patients likely to have a diminished response to vaccination
        d. In the setting of an outbreak, when immediate protection of unvaccinated or recently vaccinated patients at high risk of complications is desired
    3. Chemoprophylaxis with antiviral drugs is not recommended for healthy persons exposed to seasonal influenza.
    4. Give for 2 wk in the case of late vaccination and for the duration of the flu season in all other patients.
    5. Treatment should not wait for laboratory confirmation of influenza.
    6. Do not give aspirin or aspirin-containing products to children with influenza-like illness due to the risk of Reye syndrome.

- Other prevention strategies:
  1. Hand hygiene, cough etiquette (cover your cough), respiratory hygiene (use of tissues, facemasks for the ill and proper disposal).
  2. Seasonal flu personal protective equipment (PPE)—wear gloves and gowns as per universal/standard precautions. Per the CDC, wear a facemask, adhering to Droplet Precautions for 7 days after illness onset or until 24 hr after fever and respiratory symptoms are resolved, whichever is longer. Patient placement in a negative pressure room and N95 respirator for health care workers are recommended when conducting aerosol-generating procedures.
  3. Highly pathogenic Asian avian influenza (HPAI) includes H5N1, H7N9, H5N2, and H5N8. CDC recommends wearing eye protection, N95 respirator, gown, and gloves as for airborne and contact precautions.
  4. Management of ill health care workers—exclude from work until at least 24 hr after they no longer have a fever (without the use of fever-reducing medication). Extended exclusion time period when caring for severely immunocompromised patients.
  5. Standard cleaning and disinfection procedures.
- The Centers for Medicare and Medicaid Services links health care worker vaccine acceptance with payment for performance.

Influenza, Avian

BASIC INFORMATION

DEFINITION

Avian influenza is a virus originating in birds that has the capacity to infect humans. The prior influenza pandemics of the 20th century (from the devastating 1918 pandemic [H1N1], in which 40 to 100 million people died, to the lesser pandemics of 1957 [H2N2] and 1968 [H3N3], of 1 to 6 million deaths) were caused by highly virulent, efficiently transmitted influenzas that evolved from avian strains.

The highly pathogenic avian influenza A (H5N1), which emerged in 1997 in Hong Kong and is capable of only incidentally infecting humans, had threatened to bring another pandemic flu. It has infected over 850 persons worldwide and has a high case fatality rate of 55% (62 total cases in 2011) as it spread via migrating waterfowl from Asia to Europe and Africa.

However, the worldwide epidemic of a novel influenza strain in 2009 to 2010 with millions of cases was not with this virus but with the influenza A (H1N1) virus, which was a reassortment human–swine–avian virus.

In 2013, a new novel avian influenza emerged in China: H7N9, of which there were >1300 lab-confirmed cases. To date, there is no evidence of sustained transmission among humans for this virus, but there have been a few small clusters. The number of new cases was only 3 in 2017 to 2018. See related topic "Influenza."

SYNONYMS

Bird flu
Pandemic flu

ICD-10CM CODE

J09 Influenza due to certain identified influenza virus

EPIDEMIOLOGY & DEMOGRAPHICS

Avian influenza A H5N1 is an influenza virus related to those that bring our yearly influenzas, against which populations are routinely vaccinated. Influenza viruses are enveloped RNA viruses with segmented genomes and great antigenic diversity. They are categorized by their core proteins (A, B, C), species of origin (avian, swine, human), geographic site of isolation, serial number, and influenza subtypes based on the major antigenic surface glycoproteins, hemagglutinin (HA), and neuraminidase (NA). Example: H5N1 refers to hemagglutinin subtype 5 and neuraminidase subtype 1.

Often human and avian viruses meet and re-sort in a pig respiratory system. Southeast Asia is often the birthplace of new flu strains because birds, pigs, and people live in close proximity. It is where avian influenza A H5N1 and H7N9 emerged, first infecting domestic poultry and then wild birds that migrated across Eurasia. It is transmitted directly from birds to their keepers. Antigenic drift or shift may eventually allow avian influenza A H5N1 to gain the ability to be easily transmissible from human to human, transforming it from a highly virulent influenza strain to a pandemic flu.

PREDOMINANT SEX AND AGE: Children and young adults

RISK FACTORS: Poultry work, possibly swine work (in case of reassortment), travel to affected areas

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Presenting features include fever of at least 100.4° F (38° C) with leukopenia or lymphopenia nearly always followed by viral pneumonia with escalating respiratory distress.
- Ventilatory support is often required within 48 hr of hospitalization for acute respiratory distress syndrome (ARDS).
- Symptom onset is 2 to 5 days after exposure, longer than with human influenza.
- Respiratory symptoms may also be accompanied by watery diarrhea.
- Complications include respiratory failure, renal dysfunction, cardiac compromise, pulmonary hemorrhage, pneumothorax, and multiorgan failure. A common cause of death is superinfection with bacterial pneumonias.

ETIOLOGY

H5N1 resists host antiviral cytokines, inducing excessive host proinflammatory responses. It may cause death by "cytokine storm" rather than by inherent pathogenicity. It attaches to sialic acid molecules via an α2-3 galactose receptor (common in birds) also found in human alveoli, leading to heavy damage to lower lungs. It causes severe pulmonary injury with diffuse alveolar damage. In the bone marrow, there is a reactive histiocytosis with hemophagocytosis that may lead to pancytopenia.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Atypical pneumonia, typical respiratory virus infections (e.g., influenza, respiratory syncytial virus), severe acute respiratory syndrome, upper respiratory infection with conjunctivitis (e.g., adenovirus). Clinical symptoms are indistinguishable from those of other illnesses.

WORKUP

Comprehensive travel, occupational, and epidemiologic history

LABORATORY TESTS

- Aspartate aminotransferase, alanine aminotransferase, blood urea nitrogen, creatinine, complete blood count should be performed.
- Throat swab within 3 days of onset of symptoms to be sent for viral culture and polymerase chain reaction assay for avian influenza A (H5N1) RNA with appropriate biosafety precautions. The throat swab is more effective than nasal swabs because avian influenza preferentially infects the throat and lower respiratory tract. In the U.S., the FDA has approved the release of influenza H/A5 (Asian lineage) Virus real-time reverse transcription-PCR primer and probe set for more than 140 labs in 50 states, which will return preliminary results in 4 hr. An rRT-PCR has also been developed for the influenza A H7N9 virus.
- High-risk patients who must be tested include those with history of travel within 10 days of symptom onset to a country with documented H5N1 avian flu as well as patients with radiographically confirmed pneumonia, ARDS, or severe respiratory illness without an alternate etiology.
- Low-risk patients are those who have contact with domestic poultry or contact with people who have traveled to a country with documented H5N1 avian flu who have fever >38° C (>100.4° F) and cough, sore throat, and shortness of breath.

IMAGING STUDIES

- Chest radiography detects infiltrates a median of 7 days after onset of fever. They may be diffuse, multifocal or patchy infiltrates, or interstitial infiltrates or segmental or lobular consolidation. Progression to respiratory failure is indicated by diffuse bilateral ground-glass infiltrates.
- See "Imaging Studies" in the "Acute Respiratory Distress Syndrome" topic.

TREATMENT

- Vaccines and antivirals are the usual means for preventing and treating flu, but there are limited supplies worldwide. A subvirion H1N1 vaccine was approved by the FDA in 2007. The traditional means of vaccine production using embryonated hens' eggs has been limited because the bird flu kills the eggs. Promising new vaccine production methods are advancing through the experimental stages, including adenovirus vectors that have the possibility of allowing rapid large-scale production of vaccines.
- Beginning in the 2015 to 2016 flu season, an H1N1 component was added to the seasonal flu vaccine, which traditionally had been a bivalent vaccine (one strain of influenza A and one of influenza B) into a trivalent vaccine (two influenza A strains, including an H1N1 stain and an influenza B strain). See "Influenza."

NONPHARMACOLOGIC THERAPY

- N95 particulate masks prevent person-to-person transmission of H5N1. Surgical masks also likely prevent transmission of the virus as was seen in the H1N1 pandemic.
- In preparation for pandemic flu, increase worldwide surveillance and disease reporting, kill infected birds, increase the numbers of available intensive care unit beds with mechanical ventilators and increase emergency capacity, educate medical personnel and the public, and produce vaccines.
- In response, use influenza surveillance, social distancing (school closures), travel restrictions, quarantine, respirator masks, communications networking, and international teamwork to cordon off affected areas.

ACUTE GENERAL Rx

- The neuraminidase inhibitor oseltamivir can reduce the severity and duration of symptoms if treatment is initiated in the first 48 hr after symptom onset.
  1. Treatment: Adults: 75 mg PO twice daily for 5 days
  2. Postexposure prophylaxis: 75 mg PO daily for 7 to 10 days
- H5N1 demonstrates amantadine and rimantadine resistance.
- Peramivir: An IV neuraminidase inhibitor was FDA approved in December 2014. It has a long half-life, allowing for once daily dosing. It is effective against a variety of influenza A and B subtypes.

PEARLS & CONSIDERATIONS

PREVENTION

Inguinal Hernia

BASIC INFORMATION

DEFINITION

Inguinal hernias are characterized by their location and reducibility. An ***indirect*** inguinal hernia courses from the internal inguinal ring, toward the external inguinal ring, and into the scrotum. A ***direct*** inguinal hernia bulges directly outward and is medial to the internal inguinal ring. An irreducible (i.e., not able to be pushed back into the abdominal cavity) inguinal hernia is ***incarcerated*** and may be associated with moderate to severe pain, tenderness to palpation and/or overlying erythema. A ***strangulated*** inguinal hernia is an incarcerated hernia with a compromised blood supply and ischemia resulting in moderate to severe pain, tenderness to palpation, overlying erythema, +/- fever, and/or nausea and vomiting.

SYNONYMS

Groin hernia
Indirect hernia
Direct hernia

ICD-10CM CODES

K40	Inguinal hernia
K40.9	Inguinal hernia without obstruction or gangrene

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Incidence is unknown.
PREVALENCE: Approximately 5% of the population experiences an abdominal hernia, and 75% of these are inguinal hernias. Two thirds of inguinal hernias are indirect, and the rest are direct.
PREDOMINANT SEX AND AGE: Male gender and increasing age are associated with increased incidence of inguinal hernias.
PEAK INCIDENCE: Increases with age
RISK FACTORS: History of hernia repair, older age, male sex, Caucasian race, family history, smoking

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with asymptomatic or mildly symptomatic inguinal hernias often present with a complaint of groin bulging, discomfort or both.
- Patients with incarcerated or strangulated inguinal hernias present with moderate to severe groin pain and tenderness to palpation and may have overlying erythema, fever, nausea or vomiting.
- The most common physical exam findings are palpable groin bulging within the scrotum (indirect hernia) (Fig. E1) or inguinal region (direct hernia); this may be best appreciated in the standing position. In males, an asymptomatic indirect hernia may be detected by invaginating the scrotal tissue, following the spermatic cord into the external femoral ring and instructing the patient to perform the Valsalva maneuver.

ETIOLOGY

Inguinal hernias are caused by a defect in the abdominal wall that is present at birth or develops with age.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other hernias: Femoral, abdominal (Fig. E2)
- Testicular: Testicular torsion, epididymitis
- Pregnant patient: Round ligament varicosity
- Vascular: Femoral aneurysm or pseudoaneurysm
- Lymphatic: Inguinal lymphadenitis, lymphogranuloma venereum

WORKUP

- Uncomplicated inguinal hernias may be diagnosed based on history or physical examination.
- If the diagnosis is unclear and the patient is asymptomatic or mildly symptomatic (mild discomfort), proceed to imaging.
- If the patient is moderately or severely symptomatic, or incarcerated or strangulated hernia is suspected, refer the patient to an emergency department.

LABORATORY TESTS

- Asymptomatic and mildly symptomatic patients require no laboratory testing.
- All other patients should be referred to an emergent setting for a complete blood count, basic metabolic panel, lactate, prothrombin time/international normalized ratio and type and screen.

IMAGING STUDIES

- If there is low concern for incarcerated or strangulated hernia (e.g., groin bulging with mild discomfort), yet the diagnosis remains unclear, obtain a groin ultrasound.
- If there is clinical concern for incarcerated or strangulated hernia (e.g., moderate to severe pain, overlying redness, nausea, vomiting, fever, increased bowel sounds), refer to the emergency department for CT abdomen/pelvis with IV contrast.

TREATMENT

- Asymptomatic and mildly symptomatic inguinal hernias can be referred on an outpatient basis to a general surgeon for expectant management.
- Suspected incarcerated or strangulated hernias should be referred to an emergency department for reduction and/or emergent surgical consultation.

NONPHARMACOLOGIC THERAPY

Although spring trusses are more commonly used in Europe, a surgeon may fit the patient with one during a period of watchful waiting.

ACUTE GENERAL Rx

- Patients with suspected incarcerated hernias need emergent reduction. This is best accomplished in an emergency department setting given the frequent need for intravenous medications.
- Incarcerated hernias sometimes can be reduced with firm direct pressure when the patient is in the Trendelenburg position; most require intravenous analgesia.

CHRONIC Rx

Patients with easily reducible, mildly symptomatic hernias can be referred to a general surgeon for expectant management.

DISPOSITION

- Patients without suspected incarcerated or strangulated hernia can be dispositioned home.
- Patients with moderate or severely symptomatic hernias or suspected incarcerated or strangulated hernias should be dispositioned to an emergent setting.

REFERRAL

- Mildly symptomatic patients should be referred to a general surgeon on an outpatient basis for watchful waiting.
- Moderately symptomatic patients (with no signs or symptoms of incarceration) should be referred urgently to a general surgeon for consideration of elective repair.
- Patients who present with potential incarceration or strangulation should be referred to an emergency department for reduction and emergent surgical consultation.

SUGGESTED READINGS

BASIC INFORMATION

DEFINITION

Insomnia is a disturbance of initiating or maintaining sleep. Restless, nonrestorative sleep may also be described as another specified insomnia. The disturbance occurs despite adequate circumstances and opportunity for sleep and is accompanied by significant distress or impairment in daytime functioning.

In the new DSM-5, the diagnosis of primary insomnia has been replaced with **insomnia disorder** in order to avoid the distinction between primary and secondary forms of the disorder. This paradigm shift relates to widely accepted research in the field suggesting that there is a bidirectional and interactive relationship between insomnia and any coexisting medical and/or mental disorders.

SYNONYMS

Sleeplessness
Sleep disorder, sleep disturbance, dyssomnia (NOTE: The terms *sleep disorder, sleep disturbance,* and *dyssomnia* are generic and can refer to disorders of wakefulness [hypersomnia] or sleep-related behavior disorders [parasomnias])
Insomnia disorder
Chronic insomnia disorder

ICD-10CM CODES

F51.01	Primary insomnia
F51.02	Adjustment insomnia
F51.03	Paradoxical insomnia
F51.04	Psychophysiologic insomnia
F51.05	Insomnia due to other mental disorder
F51.09	Other insomnia not due to a substance or known physiological condition
G47.00	Insomnia, unspecified
G47.01	Insomnia due to medical condition
G47.09	Other insomnia
Z73.810	Behavioral insomnia of childhood, sleep-onset association type
Z73.811	Behavioral insomnia of childhood, limit setting type
Z73.812	Behavioral insomnia of childhood, combined type
Z73.819	Behavioral insomnia of childhood, unspecified type

DSM-5 CODES
Depends on specific diagnosis.

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 20% to 30% of adults experience occasional bouts of acute insomnia.
PREVALENCE (IN U.S.): The prevalence of chronic insomnia disorder ranges from 6% to 10%.
PREDOMINANT SEX: More common in women
PREDOMINANT AGE: Transient insomnia can occur at any age; persistent insomnia can also occur at any age but is more common after age 60 yr.
GENETICS: Can run in families and may be genetically influenced. Circadian rhythm disorders and narcolepsy have been traced to specific genes.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Difficulty initiating sleep, inability to maintain sleep, and/or early morning awakening.
- Significant distress or impairment in daytime functioning such as fatigue or low energy, sleepiness, cognitive impairments, mood disturbances, and/or physiologic or behavioral problems.
- Difficulty occurs despite adequate opportunity for sleep.
- Symptoms may be acute and self-limited, chronic but intermittent, or chronic and frequent.

ETIOLOGY

- Transient insomnia:
  1. Any stressful biopsychosocial change in life circumstance (e.g., marriage, divorce, birth of a child, loss of a loved one, illness, retirement, etc.)
  2. Travel (across time zones)
  3. Environmental disruptions (noise, heat, cold, poor bedding, bed partners, unfamiliar surroundings, etc.)
- Persistent insomnia (Fig. 1):
  1. Mood and anxiety disorders (depression, hypomania/mania, PTSD)
  2. Psychophysiologic insomnia (conditioned arousal, extended sleep opportunity, sleep effort, poor sleep hygiene)
  3. Sleep-related breathing disorders (e.g., obstructive apnea and hypopnea, increased upper airway resistance)
  4. Chronobiologic (also known as circadian rhythm) disorder (delayed sleep phase, advanced sleep phase, shift work, non-24-hr sleep-wake disorder secondary to blindness)
  5. Drug and alcohol abuse
  6. Restless legs syndrome and periodic leg movements
  7. Neurodegenerative (Alzheimer disease, Parkinson disease, etc.)
  8. Medical (pain, GERD, nocturia, orthopnea, menopause, medications, etc.)

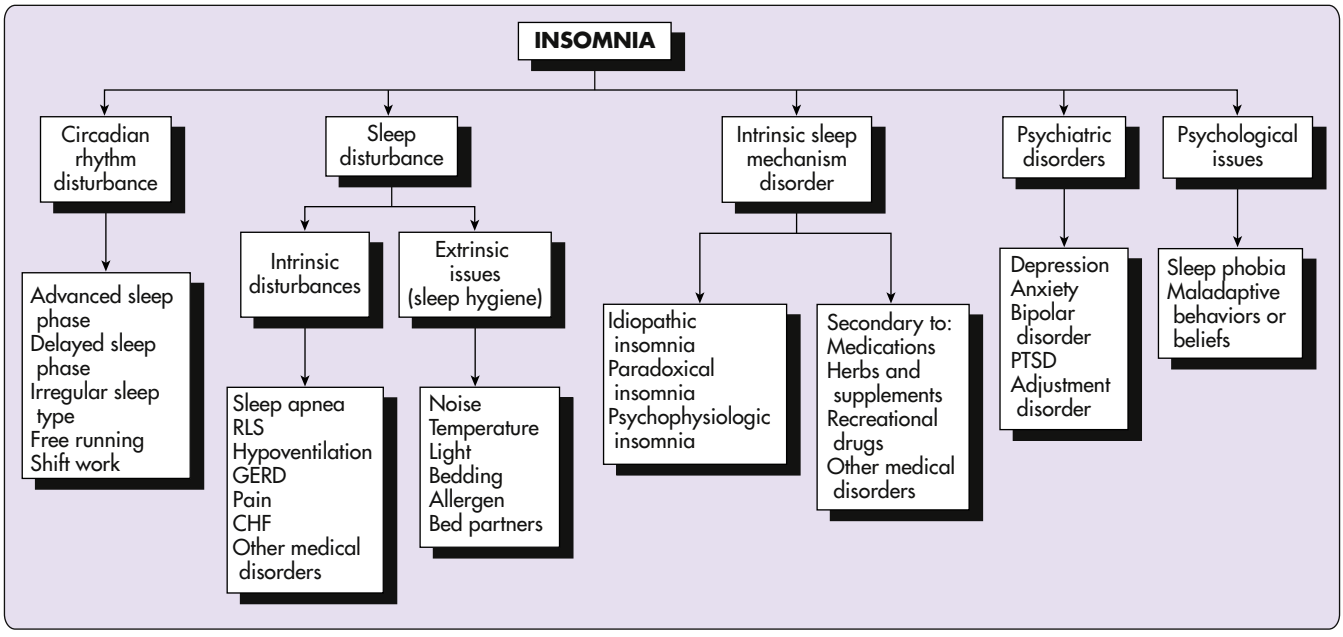

FIG. 1 Diagnostic flowchart to approach insomnia. *CHF,* Congestive heart failure; *GERD,* gastroesophageal reflux disease; *PTSD,* posttraumatic stress disorder; *RLS,* restless legs syndrome. (From Kryger MH et al: *Principles and practice of sleep medicine,* ed 6, Philadelphia, 2017, Elsevier.)

DIAGNOSIS

Diagnostic and Statistical Manual of Mental Disorders (DSM-5) criteria for the diagnosis of insomnia disorder is as follows[1]:

- Dissatisfaction with sleep quantity or quality, with one or more of the following symptoms:
  1. Difficulty initiating sleep
  2. Difficulty maintaining sleep, characterized by frequent awakenings or trouble returning to sleep after awakenings
  3. Early-morning awakening with inability to return to sleep
- The sleep disturbance causes clinically significant distress or impairment in daytime functioning, as evidenced by at least one of the following:
  1. Fatigue or low energy
  2. Daytime sleepiness
  3. Impaired attention, concentration, or memory
  4. Mood disturbance
  5. Behavioral difficulties
  6. Impaired occupational or academic function
  7. Impaired interpersonal or social function
  8. Negative effect on caregiver or family functioning
- The sleep difficulty occurs at least 3 nights per wk, is present for at least 3 mo, and occurs despite adequate opportunity for sleep

DIFFERENTIAL DIAGNOSIS

Insomnia disorder is only ruled out when the disorder is seen exclusively during other etiologies (see "Etiology"). It can be precipitated by a "primary" medical, mental health, or other sleep-wake disorder, but often continues as a comorbid condition even after the "primary disorder" has been treated. For medical disorders such as obesity, diabetes mellitus, and renal disease, obstructive sleep apnea is a frequent complication and must be ruled out. Insomnia remains the most resistant symptom following the treatment of depression. Its continued expression complicates the treatment of depression, reduces remission rates, and increases the likelihood of relapse of depression. Once evidence has been established of ongoing perpetuating factors such as conditioned arousal, sleep extension, worry and rumination about sleep, and sleep effort, this predicts that the insomnia will not likely remit even with the remission of the original precipitating stressor or disorder. It is also important to note that sleep dysregulation is a frequent early sign of a manic episode. Restoring sleep will often help reduce manic symptoms.

Circadian rhythm disturbances such as those seen in shift workers, blind individuals who lack a light-dark cycle to synchronize the body clock, adolescents and young adults with delayed sleep phase syndrome, and people with jet lag can mimic signs and symptoms of insomnia, especially initial and late insomnia. These disorders can be treated with chronobiologic therapies such as chronotherapy, bright light exposure, melatonin, or melatonin agonists. However, the timing of these interventions can be critical to outcome and constitutes therapies that are very different from standard medical and/or behavioral treatment for insomnia.

[1]American Psychiatric Association: *Diagnostic and statistical manual of mental disorders,* 5th ed, American Psychiatric Publishing, Arlington, VA, 2013.

BOX 1 Sleep Habits (Sleep Hygiene Measures) That May Improve Sleep

1. Reduce caffeine, alcohol, or tobacco late in the day or especially evening.
2. Avoid heavy meals at night, but consider a light snack before bed such as toast or a handful of nuts.
3. Increase daytime activity, but avoid exercise within 3-5 hours of bedtime.
4. Increase daytime exposure to natural light.
5. Reduce liquids in the last 4 hours before bedtime.
6. Consider white noise as background sound for the sleep environment.
7. Maintain regular bed and wake times.
8. Go to bed with calm mind; resolve arguments or set a time earlier in the day to review problems and perhaps write down plans, solutions, or things to do.
9. Keep light exposure in the middle of the night to a minimum when awake and attenuate morning light in the bedroom.
10. Avoid pets in the bed.

WORKUP

- History (with bed partner interview, if possible)
- Medication review (e.g., steroids can disrupt sleep)
- Sleep diary for 2 wk (Consider the Consensus Sleep Diary [Carney CE et al in Suggested Readings])
- Wrist actigraphy (detects gross limb movements and can distinguish wake from sleep states) as an adjunct to a sleep diary provides some objective verification of the diary data and provides prospective measurement of sleep and wake across the 24-hr day. Actigraphy should not be considered an alternative to prospective sleep diary data
- Validated sleep-quality rating scale (optional).
  1. Insomnia Severity Index
  2. Pittsburgh Sleep Quality Index
  3. Epworth Sleepiness Scale (see Daytime Sleepiness Test at www.sleepfoundation.org)

LABORATORY TESTS

- Evaluate for anemia (especially low ferritin level), uremia (for restless legs), thyroid function (if other signs present).
- Polysomnography (in home or in sleep laboratory) is not standard for insomnia but should be reserved for patients whose history suggests specific sleep-related breathing or movement disorders. It is indicated for symptoms suggestive of daytime sleepiness (obstructive sleep apnea, narcolepsy), nonrestorative sleep (periodic leg movements, chronic pain conditions), or sleep behavior suggesting parasomnia (somnambulism, REM sleep behavior).

IMAGING STUDIES

- Not generally helpful
- Brain CT or MRI for severe daytime sleepiness or acute onset

TREATMENT

NONPHARMACOLOGIC THERAPY

- Sleep hygiene measures (Box 1) as a monotherapy are not very effective in cases of persistent insomnia. More useful if combined with procedures described next.
- Cognitive-behavioral therapy (CBT-I) has been shown to reduce time to fall asleep and time awake during the night, can reduce reliance on sleep medications, and has shown lasting effects after treatment has been discontinued. It should be the initial treatment option in persons with chronic insomnia.
- The standard components that comprise CBT-I are as follows:
  1. Stimulus control, which addresses the conditioned cues that create arousal when attempting to sleep by restricting activity in bed to sleep and sex and not permitting sleep effort, worrying, watching TV, reading, etc., in bed (reconditioning of this type can take several days or wks—patients should not come to expect positive changes on the first night).
  2. Sleep restriction therapy reduces sleep opportunity to the average amount of total sleep time the patient is getting as determined by baseline sleep diary data. Sleep time is increased incrementally, based on improving sleep efficiency. Note that restricted time in bed should never be <5 hr. For the elderly and infirm, average total sleep time plus 30 min is sometimes considered. For patients whose estimated average total sleep time is <4 hr, a diagnosis of paradoxical insomnia should be considered and CBT-I would be contraindicated. Caution should also be exercised when using sleep restriction therapy in bipolar disorder and seizure disorders, as sleep deprivation early in treatment can precipitate a manic episode and lower seizure threshold, respectively.
  3. Cognitive therapy targets unhelpful beliefs and worries about sleep, negative and unwanted thoughts, sleep effort, selective attention bias and monitoring, misperception of sleep and daytime deficits, and counterproductive safety behaviors that are thought to maintain insomnia.
  4. Sleep hygiene is aimed at improving sleep habits (e.g., initiating or maintaining exercise, avoiding heavy meals at night, and altering the timing of or eliminating caffeine, nicotine, and alcohol intake). Environmental factors should also be addressed (e.g., using white noise and/or light attenuating bedroom). Caffeine sometimes can prove useful when used judiciously in the morning and early

afternoon to combat the increased fatigue and somnolence that are produced early in therapy with sleep restriction and stimulus control. In addition, exercise contingently applied to daytime fatigue can also help to improve alertness during the day and increase sleep pressure at bedtime.

5. Relaxation exercises (e.g., progressive muscle relaxation, diaphragmatic breathing) may be good adjunctive therapy, especially in highly anxious patients, but are not thought to be essential in CBT-I. Increasingly, mindfulness-based practices are being effectively utilized alone and in combination with other elements of CBT-I. Mindfulness may help patients to adopt a more flexible and accepting stance toward insomnia.

ACUTE GENERAL Rx

- Benzodiazepine receptor agonists zolpidem 5 mg and zaleplon 5 mg for sleep-onset insomnia, and zolpidem continuous-release formulation 6.25 to 12.5 mg and eszopiclone 1 to 3 mg for maintenance insomnia.
- Suvorexant is an orexin receptor antagonist FDA approved for insomnia. Signaling of orexin neuropeptides sustains wakefulness. Suvorexant promotes sleep by blocking orexin neuropeptides from binding to their receptors. The initial dose is 10 mg once daily within 30 min of bedtime. Most common side effect (10%) is next-day somnolence.
- Benzodiazepine sedative-hypnotics (e.g., temazepam 7.5 to 30 mg, triazolam 0.125 to 0.25 mg).
- A low-dose formulation (6 mg) of the tricyclic antidepressant doxepin, brand name Silenor, is also FDA approved for treatment of insomnia associated with sleep maintenance. This dose retains the hypnotic effect of doxepin without the typical tricyclic effects. A generic 10 mg/ml liquid formulation of doxepin is also available.
- In critical care: Lorazepam 0.25 to 0.5 mg PO, SL, or IV as needed for sleep. In patients with acute delirium, haloperidol 0.25 to 0.5 mg IV as needed up to 2 mg/day may be less likely to worsen confusion.
- Melatonin 3 to 5 mg has been used for delayed phase insomnia with shortening of sleep initiation time but no real change in sleep efficiency. There can be side effects, especially at higher doses.
- Melatonin agonist ramelteon 8 mg for sleep-onset insomnia when a mild agent without benzodiazepine side effects is desired.
- Avoid antihistamines except for occasional use.
- Optimize treatment of medical symptoms, especially pain.
- Most prescription and over-the-counter medications carry significant risk of adverse events and drug interactions, especially in the geriatric patient. Preferred pharmacotherapeutic agents in the elderly are zolpidem, zaleplon, eszopiclone, and ramelteon.

CHRONIC Rx

- Considerable research supports the efficacy of CBT-I, with acute treatment outcomes equivalent to pharmacotherapy, and better long-term outcomes and maintenance of treatment gains. Although there is limited availability of CBT-I specialists, especially in certain geographic areas, there are now online interactive evidence-based self-help programs that can serve as an effective base for a stepped model of care. Patients who fail these attempts should still be encouraged to seek more tailored treatment with a specialist, especially when the insomnia is comorbid with other conditions.
- When CBT-I is applied to patients with related comorbidities (e.g., depression, chronic pain), evidence suggests that targeted treatment for insomnia not only results in significant improvement of the insomnia but, in many cases, influences the course of the related comorbidities. For example, when CBT-I is applied concurrently with antidepressants, it has the effect of doubling remission rates in depression and reduces suicidal ideation by up to 65%. In a recent study of patients with comorbid depression and insomnia, head-to-head comparison of Internet-based treatments for depression (dCBT-D) and insomnia (dCBT-I) demonstrated that dCBT-I outperformed dCBT-D for insomnia and matched its efficacy in depression.
- Note that the American College of Physicians recently published clinical guidelines for the management of chronic insomnia disorder, suggesting that CBT-I be the first-line treatment for insomnia and recommending that it be attempted before pharmacologic approaches when possible.
- Three sedative-hypnotics—zolpidem continuous release, eszopiclone, and ramelteon—FDA approved for long-term use.
- Some evidence shows that benzodiazepines and benzodiazepine receptor agonists can be used for chronic insomnia on either intermittent or nightly use with moderate risk of tolerance and dependence but low risk of addiction.
- Sedating antidepressants (e.g., trazodone 25 to 150 mg, mirtazapine 7.5 to 30 mg, amitriptyline 25 to 50 mg, doxepin 10 mg) are in widespread use, with limited data on safety and efficacy. Amitriptyline should be avoided in older adults.
- Sedating antipsychotics (e.g., quetiapine 25 to 200 mg, olanzapine 2.5 to 10 mg at night) considered for severe mood or psychotic disorders associated with insomnia.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Melatonin may shorten sleep-onset latency in some individuals. It may have more clinical utility in the management of circadian rhythm disorders. Timing of administration in these types of cases requires careful consideration and would not be often administered at bedtime.

DISPOSITION

- Transient (acute) insomnia: Usually self-limited. May require follow-up if stress-related or illness-related because of risk of depression or persistence. Prophylactic education regarding maladaptive sleep practices such as extending time in bed, and/or remaining in bed when unable to sleep, might be helpful in avoiding a more protracted course of insomnia.
- Persistent insomnia: Patients who respond well to CBT-I often continue to maintain gains at 1- and 2-yr follow-ups. Patients may need periodic follow-up to reinforce good sleep hygiene and stimulus control and for reevaluation of pharmacologic therapies. There is now a compelling amount of evidence that insomnia, if left untreated, is associated with significant negative mental and health effects over time.

REFERRAL

- A referral to a behavioral medicine specialist may be required for CBT-I or for circadian rhythm disturbances (find a directory at https://www.behavioralsleep.org)
- Excessive daytime sleepiness not obviously caused by insomnia (e.g., narcolepsy, sleep-related breathing disorder)
- Nighttime behavior suggestive of a parasomnia (e.g., somnambulism, REM behavior disorder)
- Severe insomnia not responsive to basic interventions

PEARLS & CONSIDERATIONS

COMMENTS

CBT-I often results in worse sleep and more fatigue in the short run. Patients often respond to initial worsening of symptoms as a sign of failure; however, they should be encouraged to see this as an important piece of the therapy and to stay the course as new conditioned patterns begin to emerge, sleep efficiency improves, and total sleep time gradually increases.

Patients should avoid compensating for lost sleep by extending sleep opportunity in the form of going to bed early, sleeping in, or napping. Therefore, early treatment should focus on helping patients to manage daytime fatigue and sleepiness by engaging in activities that help patients stay awake and maintain set bed and wake times.

PREVENTION

It is estimated that 50% to 70% of individuals demonstrating the syndrome of insomnia (e.g., insomnia symptoms more than 3 days per wk for a mo along with deleterious daytime sequelae) are still syndromic 1 to 5 yr later. Therefore, early intervention with medication or education to prevent the development of maladaptive compensatory behaviors (e.g., napping, sleeping late, tossing and turning in bed, avoiding or decreasing daytime activity) may help to reduce the risk of developing persistent insomnia.

PATIENT & FAMILY EDUCATION

The National Sleep Foundation (http://www.sleepfoundation.org) is a comprehensive resource for health care providers and patients.

BASIC INFORMATION

DEFINITION

Insulinoma is a pancreatic insulin-secreting tumor that leads to inappropriately elevated plasma insulin or proinsulin levels with suppression of hepatic glucose output and subsequent hypoglycemia, especially during periods of fasting.

ICD-10CM CODES

C25.4 Malignant neoplasm of endocrine pancreas
D13.7 Benign neoplasm of endocrine pancreas
D37.7 Neoplasm of uncertain or unknown behavior of other digestive organs (pancreas)

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: One case per 250,000 persons annually. 90% of insulinomas are benign.
PREDOMINANT SEX AND AGE: Insulinomas occur in both sexes (approximately 60% in women) and at all ages. In a Mayo Clinic series, the median age at diagnosis was 50 yr in sporadic cases, but 23 yr in patients with multiple endocrine neoplasia, type 1 (MEN-1).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Symptoms typically occur in the morning before breakfast (i.e., fasting hypoglycemia as opposed to reactive hypoglycemia, which is not commonly associated with insulinoma).

Neuroglycopenic Symptoms	**%**
Various combinations of diplopia, blurred vision, sweating, palpitations, or weakness	85
Confusion or abnormal behavior	80
Unconsciousness or amnesia	53
Grand mal seizures	12
Adrenergic Symptoms	**%**
Sweating	43
Tremulousness	23
Hunger, nausea	12
Palpitations	10

ETIOLOGY, PATHOLOGY, & PATHOPHYSIOLOGY

- Insulinomas are almost always solitary. Malignant insulinomas account for 5% of the total; they tend to be larger (6 cm). Metastases are usually to the liver (47%), regional lymph nodes (30%), or both.
- Insulinomas are evenly distributed in the head, body, and tail of the pancreas; ectopic insulinomas are rare (1% to 3%). Tumor size: 5% are ≤0.5 cm, 34% are 0.5 to 1 cm, 53% are 1 to 5 cm, and 8% are >5 cm.
- Histologic classification includes insulinoma in 86% of patients, adenomatosis in 5% to 15%, nesidioblastosis in 4%, and hyperplasia in 1%. Adenomatosis consists of multiple macroadenomas or microadenomas and occurs especially in patients with MEN-1. Nesidioblastosis is also a diffuse lesion in which islet cells form as buds on ductular structures.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS (OF FASTING HYPOGLYCEMIA)

Hyperinsulinism:
- Insulinoma
- Nonpancreatic tumors
- Severe congestive heart failure
- Severe renal insufficiency in non–insulin-dependent diabetes

Hepatic enzyme deficiencies or decreased hepatic glucose output (primarily in infants and children):
- Glycogen storage diseases
- Endocrine hypofunction
- Hypopituitarism
- Addison disease
- Liver failure
- Alcohol abuse
- Malnutrition

Exogenous agents:
- Sulfonylureas, biguanides
- Insulin
- Other drugs (aspirin, pentamidine)

Functional fasting hypoglycemia:
- Autoantibodies to insulin receptor or insulin

LABORATORY TESTS

- An overnight fasting blood sugar level combined with a simultaneous plasma insulin, proinsulin, and/or C peptide level will establish the existence of fasting organic hypoglycemia in 60% of patients. Table E1 describes biochemical patterns in patients with various causes of hyperinsulinemic hypoglycemia.
- If single overnight fasting glucose and insulin levels are nondiagnostic, a 72-hr fast is usually done with blood glucose and insulin levels determined at 2- to 4-hr intervals. A total of 75% of patients with insulinoma develop symptoms and a blood sugar level of <40 mg/dl by 24 hr, 92% to 98% develop these by 48 hr, and virtually all patients develop them by 72 hr. The test is considered positive for insulinoma if the plasma insulin/glucose ratio is more than 0.3. If at any point the patient becomes symptomatic, plasma insulin and glucose values should be obtained and IV glucose should be administered.
- The Endocrine Society guidelines for diagnosis of hypoglycemic disorders is based on glucose level <55 mg/dl (<3.1 mmol/L), elevated C-peptide level ≥0.61 ng/ml (≥0.2 nmol/L). Elevated insulin level ≥18 pmol/L, proinsulin level >5 pmol/L, and suppressed β-hydroxy-butyric acid level.
- An "amended" insulin-glucose ratio that accounts for the normal variation in insulin secretion according to prevailing glycemia has been shown to improve diagnostic accuracy of insulinomas. The "amended" insulin-glucose ratio is derived from the simple insulin-glucose ratio by subtracting 30 mg/dl (1.7 mmol/L) from the measured glucose concentrations.

IMAGING STUDIES

- Abdominal CT scan or MRI (Fig. E1) detects half to two thirds of insulinomas (abdominal ultrasound is not effective); should be done only after laboratory tests for insulinoma have confirmed the diagnosis
- Intraoperative ultrasound
- Arteriography
- Octreotide scan (Fig. E2)

TREATMENT

NONPHARMACOLOGIC THERAPY

- Enucleation of single insulinoma
- Partial pancreatectomy for multiple adenomas

ACUTE GENERAL Rx

- Carbohydrate administration
- Diazoxide directly inhibits insulin release and has an extrapancreatic, hyperglycemic effect that enhances glycogenolysis
- Lanreotide and octreotide (somatostatin analogues)
- Streptozotocin

REFERRAL

To an endocrinologist and then to an endocrine surgeon

Intermittent Explosive Disorder (IED)

BASIC INFORMATION

DEFINITION

Multiple episodes of impulsive verbal or physical aggression out of proportion to perceived stressors or threats

SYNONYM

IED

ICD-10CM CODES

F63.81 Intermittent explosive disorder
F63.8 Other habit and impulse disorders
F63.9 Habit and impulse disorder, unspecified

DSM-5 CODE

312.34 Intermittent explosive disorder

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Unknown
PEAK INCIDENCE: Occurs earlier in life
PREVALENCE: Lifetime prevalence of 6% to 7%
PREDOMINANT SEX AND AGE: Occurs more so in males and in people under the age of 50.
GENETICS: Patients with intermittent explosive disorder (IED) are more likely to have first-degree relatives with the disorder. In addition, adoption and twin studies point to a >50% of the variance in aggression related to genetic factors.
RISK FACTORS: Prior history of violence, exposure to trauma, comorbid depression, anxiety, substance abuse or dependence, or cluster B personality disorders. There is evidence that substance use disorders place patients at risk of developing this condition, as opposed to the other way around.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Several episodes of verbal or physical aggression; the latter may include attacks on others or destruction of physical property.
- The aggression is out of proportion to any perceived stressors or threats.
- The aggression is impulsive.
- The aggression causes distress.
- The aggression is not accounted for by another disease process.
- The patient is at least 6 yr of age.

ETIOLOGY

- Potentially an imbalance between aggression, originating from the amygdala and other limbic structures, and orbitofrontal, and anterior cingulate cortices. The temporoparietal junction, an area involved in empathy and social cognitive processes, seems to be activated in treatment with Lexapro (see the following). This view is supported by multiple studies involving functional neuroimaging, specifically fMRI.
- From a neurochemical basis, a deficiency in the neurotransmitter serotonin appears involved. PET imaging shows a decrease in serotonergic innervation in the anterior cingulate cortex and serotonergic agents treat IED (see the following).
- Endocannabinoids may play a role. One study showed that circulating levels of anandamide were inversely related to affect regulation.
- Inflammation may play a role. Numerous markers of oxidative stress and aggression are more increased in patients with IED than in controls.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Psychiatrically, patients may suffer from mood, anxiety, psychotic, and personality disorders (primarily antisocial and borderline). In addition, patients may be under the effects of substances, or in withdrawal from them.
- Neuropsychiatrically, dementia, delirium, temporal lobe epilepsy, cardiovascular disease, multiple sclerosis, and brain lesions can all cause similar behavior. IED is often thought of as part of a frontal network syndrome related to impairment in prefrontal cortical functioning, which can sometimes present with neurologic soft signs (frontal release signs).
- If delirium is expected, a wider, more systemic differential diagnosis should be explored.

WORKUP

A thorough mental status and neurologic examination should be performed. In addition, there should be careful consideration for other neuropsychiatric conditions if the history points in that direction.

LABORATORY TESTS

- Urine toxicology screen, as substance abuse is highly comorbid.
- Dementia workup when appropriate: CBC, brain MRI or at least a head CT, Chem 7, B_{12}, TSH, Folate, RPR.
- Delirium workup when appropriate; associated signs and symptoms may be helpful for guidance, especially in clinical settings.

IMAGING STUDIES

- Brain MRI or head CT, in cases where dementia, delirium, neurovascular disease, or brain lesions are expected. The appropriate test should be ordered depending on the particulars of the case (i.e., MRI to evaluate for MS and subcortical disease).
- EEG is indicated to evaluate for seizure-related conditions.

TREATMENT (TABLE E1)

- Selective serotonin reuptake inhibitors (SSRIs) are considered first-line therapy. Multiple studies have been performed on fluoxetine, up to 60 mg per day, though it is not unreasonable to try other SSRIs given similar mechanisms of action. Cost, side effects, drug half-life, and drug-drug interactions need to be considered. Starting at 20 mg per day, and increasing by 10 mg every other wk, for a total of a 12-wk trial, is recommended.
- Multiple large trials and meta-analyses also point to the efficacy of phenytoin, lamotrigine, topiramate, and valproate. Unless there is a contraindication to SSRIs, AEDs should be considered second line, given their potential side effects and toxicities.
- Lithium has also shown to be helpful.
- See Table E1 for details related to particular medications.

NONPHARMACOLOGIC THERAPY

- Cognitive-behavioral therapy has been shown to be helpful for patients with IED.
- Patients are taught to examine their thoughts in relation to stressful circumstances.
- Patients can be taught to examine their somatic sensations and change these through relaxation techniques.
- Relapse prevention is focused on helping patients avoid explosive behaviors in the future.

ACUTE GENERAL Rx

See previous

COMPLEMENTARY & ALTERNATIVE MEDICINE

There is no evidence on the use of complementary or alternative medicine for this disorder.

REFERRAL

Referral to an outpatient mental health provider may be helpful.

PEARLS & CONSIDERATIONS

PREVENTION

No prevention measures have been identified.

PATIENT & FAMILY EDUCATION

Psychoeducation to the patient and family may be helpful, especially in helping to identify triggers and supporting the use of coping skills.

BASIC INFORMATION

DEFINITION

The interstitial lung diseases (ILDs) include more than 150 nonmalignant disorders, characterized by varying degrees of damage to the lung parenchyma or interstitium via inflammation and fibrosis. The term "ILD" can be confusing as processes affecting the alveolar space (e.g., pulmonary alveolar proteinosis) are also lumped under the title. A clinical classification of the interstitial lung diseases is summarized in Table 1. The diseases can generally be divided into three subgroups—those that are caused by an identifiable or suspected trigger, those that are associated with an underlying, more systemic disorder, and those that are idiopathic.

SYNONYMS

Interstitial pulmonary disease
ILD
Diffuse parenchymal lung disease (DPLD)
Interstitial pneumonia

ICD-10CM CODES

J84.17	Other interstitial pulmonary diseases with fibrosis in diseases classified elsewhere
J84.89	Other specified interstitial pulmonary diseases
J84.9	Interstitial pulmonary disease, unspecified
J84.115	Respiratory bronchiolitis interstitial lung disease
J84.848	Other interstitial lung diseases of childhood

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE AND PREVALENCE: Varies widely with type of ILD. The most common ILDs are sarcoidosis, cryptogenic organizing pneumonia, and idiopathic pulmonary fibrosis. The prevalence of these syndromes varies widely across different populations as defined by age, gender, and race.
PREDOMINANT SEX & AGE: Some ILDs are more common in women, such as those resulting from connective tissue disorders. Lymphangiomyomatosis occurs exclusively in premenopausal women. ILD caused by occupational exposures are more common in men. Most ILDs occur in people >50 yr; however, sarcoidosis most often presents in younger populations.
RISK FACTORS: Although many ILDs are categorized as idiopathic, the most common identifiable risk factors include environmental exposures such as silicone, asbestos, or bird droppings; reactions to drugs such as chemotherapeutic agents; radiation therapy; cardiac medications; and finally some history of connective tissue disease such as rheumatoid arthritis or scleroderma. Both tobacco and drug use can result in an ILD.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Shortness of breath (especially with exertion)
- Cough (dry)
- Tachypnea
- Bibasilar end-inspiratory dry crackles
- Pulmonary hypertension
- Cyanosis, clubbing

Hallmarks of ILD include a restrictive pattern and decreased diffusing capacity for carbon monoxide (DLCO) as demonstrated by pulmonary function testing. The restrictive process can be the result of a number of factors depending on the type of ILD. Different types of ILD are characterized by varying degrees of acute inflammatory changes, which are potentially reversible, and fibrosis, which is largely irreversible.

- Specific changes may be seen:
  1. Granulomatous: Accumulation of T lymphocytes, macrophages, and epithelioid cells into granulomas in lung parenchyma
  2. Inflammation and fibrosis: Injury to epithelium causes inflammation; if chronic, inflammation spreads to interstitium and vascular areas

TABLE 1 Clinical Classification of the Interstitial Lung Diseases

Connective Tissue Diseases
Scleroderma
Polymyositis-dermatomyositis
Systemic lupus erythematosus
Rheumatoid arthritis
Mixed connective tissue disease
Ankylosing spondylitis

Treatment-Related or Drug-Induced Diseases
Antibiotics (nitrofurantoin, sulfasalazine)
Antiarrhythmics (amiodarone, tocainide, propranolol)
Antiinflammatories (gold, penicillamine)
Anticonvulsants (Dilantin)
Chemotherapeutic agents (mitomycin C, bleomycin, busulfan, cyclophosphamide, chlorambucil, methotrexate, azathioprine, BCNU [carmustine], procarbazine)
Therapeutic radiation
Oxygen toxicity
Narcotics

Primary and Idiopathic Diseases
Sarcoidosis
Primary pulmonary Langerhans cell histiocytosis (eosinophilic granuloma)
Amyloidosis
Pulmonary vasculitis
Gaucher disease
Niemann-Pick disease
Hermansky-Pudlak syndrome
Neurofibromatosis
Lymphangioleiomyomatosis
Tuberous sclerosis
Idiopathic pulmonary fibrosis
Nonspecific interstitial pneumonia
Cryptogenic organizing pneumonia
Respiratory bronchiolitis ILD or desquamative interstitial pneumonia
Acute interstitial pneumonia
Lymphocytic interstitial pneumonia
Pleuroparenchymal fibroelastosis
Bone marrow transplantation
Eosinophilic pneumonia
Alveolar proteinosis
Alveolar microlithiasis
Metastatic calcification

Occupational and Environmental Diseases
Inorganic
Silicosis
Asbestosis
Hard-metal pneumoconiosis
Coal worker's pneumoconiosis
Berylliosis
Talc pneumoconiosis
Siderosis (arc welder)
Stannosis (tin)

Organic (hypersensitivity pneumonitis)
Bird breeder's lung
Farmer's lung

ILD, Interstitial lung disease.
Modified from Mason RJ: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, WB Saunders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congestive heart failure
- Pneumonia: Viral, bacterial, mycobacterial, fungal
- Pulmonary embolism
- COPD
- Pulmonary hypertension
- Vasculitis
- Metastatic malignancy manifesting as lymphangitic carcinomatosis

WORKUP

- Well-defined patterns in pulmonary function tests are usually consistent with restrictive defect (decreased FVC, FRC, RV, and TLC) owing to decreased lung compliance caused by alveolar wall thickening as a result of inflammation and fibrosis. Diffusion capacity is usually reduced also because of inflammation and thickening of alveolar walls, though nonspecific. FEV_1/FVC is usually normal or increased because lung stiffness keeps small airways open, although some conditions (e.g., sarcoidosis, hypersensitivity pneumonitis) may result in air trapping.
- Bronchoscopy and bronchoalveolar lavage (BAL) may help identify type of ILD. However, their role in defining stage of disease and response to therapy is controversial. Histologic patterns in the interstitial lung diseases and their disease associations are summarized in Table 2.
- If laboratory studies and imaging including HRCT fail in yielding a diagnosis, a surgical biopsy may be required. A common objective of performing a biopsy is to evaluate the possibility of idiopathic pulmonary fibrosis, which has a unique approach to treatment.
- Fig. 1 illustrates an algorithm for the approach to a patient with interstitial lung disease.

LABORATORY TESTS

- ABGs may be normal or show respiratory alkalosis and widened Aa gradient.
- Blood tests for connective tissue diseases, such as antinuclear antibodies,

TABLE 2 Histologic Patterns in the Interstitial Lung Diseases and Their Disease Associations

Histologic Patterns	Clinical Associations
Usual interstitial pneumonia	Idiopathic pulmonary fibrosis; connective tissue diseases (uncommon); asbestosis; chronic hypersensitivity pneumonitis; chronic aspiration pneumonia; chronic radiation pneumonitis; Hermansky-Pudlak syndrome
Nonspecific interstitial pneumonia	Idiopathic; connective tissue diseases; drugs; AIDS
Diffuse alveolar damage	Acute interstitial pneumonia (Hamman-Rich syndrome); acute respiratory distress syndrome (ARDS); drugs (cytotoxic agents, heroin, paraquat, ethchlorvynol, aspirin); toxic gas inhalation; radiation therapy; oxygen toxicity; connective tissue disease; infections
Organizing pneumonia	Cryptogenic organizing pneumonia; organizing stage of diffuse alveolar damage; drugs (amiodarone, cocaine); infections; connective tissue diseases
Desquamative interstitial pneumonia/respiratory bronchiolitis	Cigarette smoking; idiopathic DIP of childhood
Lymphocytic interstitial pneumonia	Idiopathic; hypogammaglobulinemia; autoimmune diseases, including Hashimoto thyroiditis, lupus erythematosus, primary biliary cirrhosis, Sjögren syndrome, myasthenia gravis, chronic active hepatitis; AIDS; allogeneic bone marrow transplantation
Eosinophilic pneumonia	Idiopathic acute and chronic; tropical filarial eosinophilia; parasitic infections; allergic bronchopulmonary aspergillosis; allergic granulomatosis of Churg and Strauss; hypereosinophilic syndrome; AIDS
Alveolar proteinosis	Pulmonary alveolar proteinosis; acute silicosis; aluminum dust; AIDS; myeloproliferative disorder
Diffuse alveolar hemorrhage	
with capillaritis	Wegener granulomatosis; microscopic polyangiitis; systemic lupus erythematosus; polymyositis; scleroderma; rheumatoid arthritis; mixed connective tissue disease; lung transplantation; drugs (retinoic acid, propylthiouracil, Dilantin); Behçet disease; cryoglobulinemia; Henoch-Schönlein purpura; pauci-immune glomerulonephritis; immune complex glomerulonephritis
without capillaritis	Idiopathic pulmonary hemosiderosis; systemic lupus erythematosus; Goodpasture syndrome; diffuse alveolar damage; pulmonary venoocclusive disease; mitral stenosis; lymphangioleiomyomatosis
Amyloid deposition	Primary amyloidosis; multiple myeloma; lymphocytic interstitial pneumonia
Granuloma	Sarcoidosis; hypersensitivity pneumonitis; pulmonary Langerhans cell histiocytosis; silicosis; intravenous talcosis; berylliosis; lymphocytic interstitial pneumonia; infections

AIDS, Acquired immunodeficiency syndrome; *DIP,* desquamative interstitial pneumonia.
Modified from Mason RJ: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, WB Saunders.

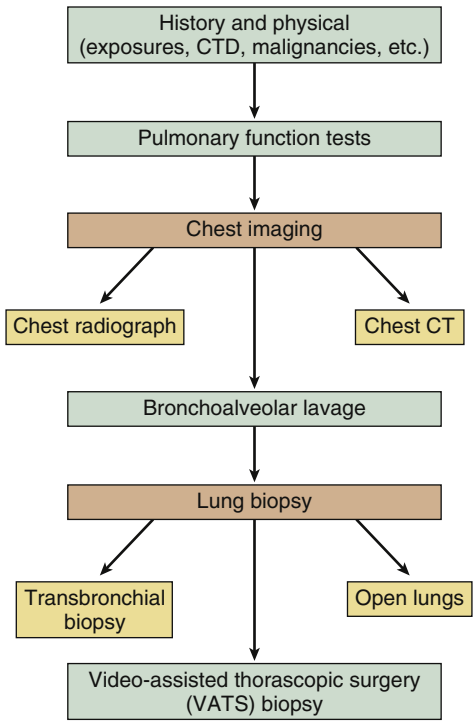

FIG. 1 Algorithm for the approach to a patient with interstitial lung disease. *CT,* computed tomography; *CTD,* connective tissue disease. (From Sellke FW et al: *Sabiston & Spencer surgery of the chest,* ed 9, Philadelphia, 2016, Elsevier.)

anti-immunoglobulin antibodies (rheumatoid factors), LDH. Laboratory findings in the interstitial lung diseases are summarized in Table 3.
- Serum precipitins confirm exposure if hypersensitivity pneumonitis is suspected.
- Antineutrophil cytoplasmic antibodies or antibasement membrane antibodies if vasculitis is suspected.
- Angiotensin-converting enzyme testing (ACE levels) in sarcoidosis is of unclear value.

IMAGING STUDIES

- Chest x-ray may be normal but commonly shows a bibasilar reticular pattern. Table 4 summarizes radiographic features of the interstitial lung diseases.
- High-resolution CT (HRCT) (Fig. 2) is the gold standard for evaluating parenchymal opacities seen on chest x-ray; it is also useful for determining potential biopsy sites.
- Echocardiography may be useful to evaluate cardiac function/dilation or to evaluate for pulmonary hypertension, which can complicate advanced ILDs.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Avoidance of tobacco and occupational exposures

ACUTE GENERAL Rx

- Supplemental oxygen in patients with hypoxemia is helpful short and long term.
- Glucocorticoids are the mainstay of therapy for many of the ILDs. Patients should be continuously reevaluated after the initiation of treatment to gauge response. If they are improved or stable, steroids may be tapered. If not, the same course may be maintained 4 additional wk. If patient's condition is unresponsive to steroids or declines as the steroids are tapered, may consider adding second agent (cyclophosphamide, azathioprine, mycophenolate, among other options).
- ILD is a common manifestation of systemic sclerosis and a leading cause of systemic

TABLE 3 Radiographic Features of the Interstitial Lung Diseases

Feature	Diseases
Upper zone–predominant disease	Radiation pneumonitis; neurofibromatosis; chronic sarcoidosis; pulmonary Langerhans cell histiocytosis; silicosis; chronic hypersensitivity pneumonitis; chronic eosinophilic pneumonia; ankylosing spondylitis; nodular rheumatoid arthritis; berylliosis; drug induced (amiodarone, gold, BCNU [carmustine]); radiation
Increased lung volumes	Lymphangioleiomyomatosis; chronic sarcoidosis; chronic pulmonary Langerhans cell histiocytosis; tuberous sclerosis; neurofibromatosis
Radiographic honeycomb lung	Idiopathic pulmonary fibrosis; connective tissue disease; asbestosis; drug induced; lymphocytic interstitial pneumonia; chronic aspiration pneumonia; hemosiderosis; Hermansky-Pudlak syndrome; alveolar proteinosis
Pneumothorax	Pulmonary Langerhans cell histiocytosis; lymphangioleiomyomatosis; tuberous sclerosis; neurofibromatosis, IPF
Kerley B lines	Lymphangitic carcinomatosis; lymphangioleiomyomatosis; left atrial hypertension (mitral valve disease, venoocclusive disease); lymphoma; amyloidosis
Lymphadenopathy	Sarcoidosis; lymphoma; lymphangitic carcinomatosis; lymphoid interstitial pneumonia; berylliosis; amyloidosis; Gaucher disease
Pleural disease	Lymphangitic carcinomatosis; connective tissue disease; asbestosis (pleural calcification); lymphangioleiomyomatosis (chylous effusion); drug induced (nitrofurantoin, radiation); sarcoidosis
Eggshell calcification of lymph nodes	Silicosis; sarcoidosis; radiation

IPF, Idiopathic pulmonary fibrosis.

TABLE 4 Laboratory Findings in the Interstitial Lung Diseases

Finding	Diseases
Leukopenia	Sarcoidosis; connective tissue disease; lymphoma; drug induced
Leukocytosis	Systemic vasculitis; hypersensitivity pneumonitis; lymphoma
Eosinophilia	Eosinophilic pneumonia; sarcoidosis; systemic vasculitis; drug induced (sulfa, methotrexate)
Thrombocytopenia	Sarcoidosis; connective tissue disease; drug induced; Gaucher disease; idiopathic pulmonary fibrosis
Hemolytic anemia	Connective tissue disease; sarcoidosis; lymphoma; drug induced; idiopathic pulmonary fibrosis
Normocytic anemia	Diffuse alveolar hemorrhage syndromes; connective tissue disease; lymphangitic carcinomatosis
Urinary sediment abnormalities	Connective tissue disease; systemic vasculitis; drug induced
Hypogammaglobulinemia	Lymphocytic interstitial pneumonia
Hypergammaglobulinemia	Connective tissue disease; sarcoidosis; systemic vasculitis; idiopathic pulmonary fibrosis; asbestosis; silicosis; lymphocytic interstitial pneumonia; lymphoma
Serum autoantibodies	Connective tissue disease; systemic vasculitis; sarcoidosis; idiopathic pulmonary fibrosis; silicosis; asbestosis; lymphocytic interstitial pneumonia
Serum immune complexes	Idiopathic pulmonary fibrosis; lymphocytic interstitial pneumonia; systemic vasculitis; connective tissue disease; pulmonary Langerhans cell histiocytosis
Serum angiotensin-converting enzyme	Sarcoidosis; hypersensitivity pneumonitis; silicosis; acute respiratory distress syndrome; Gaucher disease
Antibasement membrane antibody	Goodpasture syndrome
Antineutrophil cytoplasmic antibody	Systemic vasculitis

From Mason RJ: *Murray & Nadel's textbook of respiratory medicine,* ed 5, Philadelphia, 2010, WB Saunders.

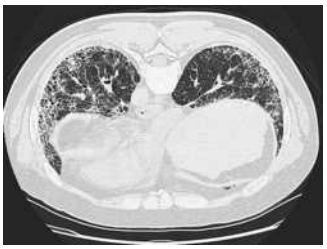

FIG. 2 High-resolution computed tomography scan of the chest shows fibrotic changes in a subpleural distribution with honeycombing consistent with usual interstitial pneumonia. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

sclerosis–related death. Nintedanib, a tyrosine kinase inhibitor, has been shown to have antifibrotic and antiinflammatory effects in early trials with resulting lower annual rate of decline in FVC in patients using nintedanib than placebo.

CHRONIC GENERAL Rx

- Outpatient pulmonary rehabilitation may be of value.
- Lung transplantation may be considered in appropriate patients in severe stages of the disease.

DISPOSITION

The prognosis is highly variable and depends on the cause, severity of illness, and initial response to treatment.

REFERRAL

- Pulmonary referral for workup and management
- Surgical referral for biopsy

PEARLS & CONSIDERATIONS

COMMENTS

It is very important when working up an ILD to take a thorough history of tobacco and drug use, prior medications, workplace and environmental exposures and pets, as well as a review of systems, including signs and symptoms that might suggest an underlying connective tissue disease.

PREVENTION

Proper industrial hygiene from a respiratory perspective is important as well as close surveillance when patients are given medications with known pulmonary toxicity. Symptoms of an ILD in the setting of an autoimmune condition need to be evaluated thoroughly.

Interstitial Nephritis PTG

BASIC INFORMATION

DEFINITION

Can be classified into two broad categories:

1. Acute interstitial nephritis (AIN):
   a. Decrease in kidney function resulting from delayed hypersensitivity immune-mediated injury, most often drug-induced
   b. Characterized on kidney biopsy by edema and leukocyte infiltration of the renal interstitium and tubules (referred to as *tubulitis*), which classically spares glomeruli and blood vessels
2. Chronic interstitial nephritis:
   a. Final common pathway of many chronic kidney diseases including diabetic kidney disease, hypertensive kidney disease, unresolved AIN, chronic obstruction, high-grade vesicoureteral reflux, and chronic bacterial infections
   b. Characterized on renal biopsy by interstitial fibrosis with mononuclear leukocyte infiltration and tubular atrophy

SYNONYMS

Acute tubulo-interstitial nephritis
Contracted kidney
Cirrhosis of the kidney
Granular kidney
Gouty kidney
Renal sclerosis
Chronic productive nephritis without exudation

ICD-10CM CODES

N05.8	Unspecified nephritic syndrome with other morphologic changes
N05.9	Unspecified nephritic syndrome with unspecified morphologic changes
N10	Acute tubulo-interstitial nephritis
N11	Chronic tubulo-interstitial nephritis
N11.8	Other chronic tubulo-interstitial nephritis
N11.9	Chronic tubulo-interstitial nephritis, unspecified
N12	Tubulo-interstitial nephritis, not specified as acute or chronic
N15	Other renal tubulo-interstitial diseases
N16	Renal tubulo-interstitial disorders in diseases classified elsewhere
N17.8	Other acute kidney failure

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- Prevalence is significantly underestimated.
- AIN is found in 0.5% to 2.6% of all kidney biopsies but may be as high as 5% to 18% in patients biopsied with acute kidney injury (AKI).

DEMOGRAPHICS:

- Increasing incidence in the elderly, attributed to reduced glomerular filtration rate (GFR), immune-mediated dysfunction, increasing medication use, and comorbidities.
- Median age at presentation is 65 yr.

RISK FACTORS:

- Advanced age (>65 yr)
- Volume depletion
- Underlying kidney disease
- Congestive heart failure
- Diabetes
- HIV infection

PHYSICAL FINDINGS & CLINICAL PRESENTATION

SIGNS AND SYMPTOMS:

- For AIN, the most common presentation is a rise in serum creatinine and blood urea nitrogen (BUN) levels that is asymptomatic. When AIN is advanced, it is associated with nonspecific symptoms of AKI from any cause, including the following:
  1. Malaise
  2. Anorexia
  3. Nausea and vomiting
  4. Oliguria or polyuria
  5. Hematuria
  6. Flank pain
- Classic triad (fever, maculopapular rash, and eosinophilia) is present in only 5% of cases:
  1. When present, the rash is usually a truncal maculopapular morbilliform eruption.
  2. Triad was characteristic of methicillin-related AIN, which has not been used in the U.S. for decades.
- A small minority present with tubulo-interstitial nephritis and uveitis (TINU) syndrome. The uveitis may be symptomatic or subclinical and may develop before, during, or after the renal injury. Adolescent females are most often affected by TINU.
- For chronic interstitial nephritis, there may be a subacute to protracted subtle rise in creatinine without any obvious symptoms as seen with AIN.

ETIOLOGY

ACUTE INTERSTITIAL NEPHRITIS:

- **Drug-induced** (70%). More than 150 agents have been implicated. AKI usually develops 10 to 14 days after exposure to the drug, but may develop sooner if there was a previous exposure.
  1. Antibiotics (beta-lactams, sulfonamides, rifampin, fluoroquinolones)
  2. NSAIDs (including selective COX-2 inhibitors)
  3. Proton pump inhibitors and H2 blockers (primarily cimetidine)
  4. Loop diuretics (furosemide, bumetanide)
  5. Antineoplastic agents
  6. Anticonvulsants
  7. Allopurinol (particularly common cause of drug rash or reaction with eosinophilia and systemic symptoms [DRESS] with AIN)
  8. Immunotherapy: Checkpoint pathway inhibitors
- **Infection** (10% to 15%). May be systemic or localized to genitourinary system.
  1. Bacteria: *Streptococci, Corynebacterium diphtheria, Legionellae, Yersinia, Mycobacteria, Mycoplasmas, Rickettsiae*
  2. Viruses: Cytomegalovirus, Epstein-Barr virus, hantaviruses, hepatitis C virus, herpes simplex virus, HIV, mumps, polyomavirus, influenza A virus
  3. Other: *Treponema pallidum, Toxoplasma gondii, Babesia* species
- **Other Causes** (15% to 20%)
  1. Idiopathic (10%)
  2. Immune disorders: Systemic lupus erythematosus, Sjögren syndrome, small-vessel vasculitides, autoimmune pancreatitis
  3. Neoplastic disorders (multiple myeloma)
  4. DRESS syndrome
  5. IgG4-related disease
  6. Hypocomplementemic tubulointerstitial nephritis (likely related to IgG4 disease)

CHRONIC INTERSTITIAL NEPHRITIS:

- Metabolic diseases (urate nephropathy, hypercalcemic nephropathy, hypokalemic nephropathy, oxalate nephropathy)
- Sarcoidosis
- Heavy metals
- Chronic urinary tract obstruction
- Aristolochic acid
- Diabetic kidney disease
- Hypertensive kidney disease

OVERLAP OF ACUTE AND CHRONIC INTERSTITIAL NEPHRITIS: Some metabolic processes and autoimmune disorders can present either as acute or chronic interstitial nephritis. For example, oxalate nephropathy can present with acute interstitial nephropathy in the setting of ethylene glycol ingestion, or with chronic interstitial nephritis in patients with prior bariatric surgery and a high oxalate-containing diet.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other causes of AKI or chronic kidney disease (CKD), including acute tubular necrosis (ATN), atheroembolic disease, glomerulonephritis, hypertensive nephrosclerosis, prerenal azotemia, obstructive nephropathy, and renal vascular disease

WORKUP

- Diagnosis is most often made by defining the temporal relationship between onset and resolution of an AKI episode with use and discontinuation of a known culprit drug.
- Gold standard for diagnosis is kidney biopsy. This is reserved for clinical situations with an unclear diagnosis, when removal of the offending agent does not result in improvement or may impact medical care, or when steroid initiation is being considered.

LABORATORY TESTS

- No single laboratory test has sufficient positive or negative predictive value to be useful in diagnosing interstitial nephritis.
- Diagnosis may be made based on clinical history, constellation of urine and serum abnormalities, and clinical course.

URINE TESTS:

- Urine eosinophilia historically was considered a marker of AIN, but this urinary finding is neither sensitive nor specific for AIN and has a low positive and negative predictive value, i.e., urine eosinophils do not establish or rule out AIN. Eosinophiluria may be found in a variety of kidney diseases.
- Urinalysis findings may include sterile pyuria, microhematuria, glucosuria, and proteinuria. Nephrotic syndrome is present in less than 1% of patients.
- Urine sediment analysis may include leukocytes, leukocyte casts, red cells, and tubular epithelial cells (Fig. E1). However, a bland urine sediment can also be seen in interstitial nephritis, especially if chronic. A lack of pyuria does not exclude AIN. Additionally, granular casts may be noted when tubulitis is present.

BLOOD TESTS:

- Serum chemistry profile: Elevated BUN, elevated creatinine, low serum phosphorus, low serum urate may be seen.
- Complete blood count with differential may reveal the following:
  1. Eosinophilia (not sensitive; if present, this finding greatly increases clinical suspicion for a systemic drug reaction. Eosinophilia may also occur in other causes of AKI including cholesterol emboli, vasculitis, and hematologic or solid organ malignancy).
  2. A hemoglobin level that is disproportionately low compared with the degree of AKI. This is attributed to loss of interstitial erythropoietin-producing cells, which may be impacted by the inflammatory cellular congestion).
- If drug-related AIN is not suspected, laboratory workup for infection, vasculitis, and autoimmune disorders may be warranted depending on the clinical context.

IMAGING STUDIES

Gallium scintigraphy, positron emission tomography, and computed tomography have been used to evaluate AIN in patients. These tests may distinguish between AIN and other forms of AKI in patients too unstable for a renal biopsy.

KIDNEY BIOPSY

Critical in diagnosis of interstitial nephritis in patients in whom the differential of AKI is broad. Biopsy findings include (Fig. E2):

- Predominant lymphocytic and monocytic infiltrate (Fig. E2, B).
- Presence of eosinophils is suggestive of drug-induced AIN (Fig. E2, C).
- Tubulitis (renal tubular invasion by inflammatory cells) is suggestive of AIN.
- Early on, inflammation is associated with edema, but may transition to fibrosis with underlying tubular atrophy as the process becomes more chronic (Fig. E2, D).
- Granuloma formation may be more suggestive of infectious AIN, especially in regions where the infectious etiologies described earlier are endemic.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Largely supportive; removal of offending agent, if known, will resolve 60% of cases.

ACUTE GENERAL Rx

- Maintain adequate hydration and urine output and avoid volume overloading.
- Identify and treat infection if present.
- Avoid nephrotoxins and medications that impair renal blood flow.
- Uveitis in TINU syndrome may be asymptomatic. Ophthalmologic exam is recommended in idiopathic AIN.
- Retrospective studies and anecdotal literature have shown that steroid treatment, initiated within 7 days of diagnosis, may reduce the requirement for chronic dialysis in patients with drug-induced AIN who have not responded to drug withdrawal alone. Steroids are the basis of treatment in idiopathic AIN, AIN associated with systemic disease, and TINU. Regimens vary. Some include an initial steroid pulse of methylprednisolone, 250 to 500 mg for 3 consecutive days, followed by 1 mg/kg prednisone. Others start with 1 mg/kg of prednisone with no intravenous, with tapering over 4 to 6 wk. Steroids are not administered to patients with significant kidney fibrosis on histologic examination.
- Cyclophosphamide, cyclosporine, and mycophenolate mofetil have all been used anecdotally as therapy in steroid-resistant disease. Among these, mycophenolate mofetil has the largest body of evidence for use as a steroid-sparing agent, if AKI recurs when steroids are tapered or discontinued, or when patients develop adverse effects from steroid therapy.

CHRONIC Rx

- Limit exposure to known nephrotoxic agents.
- Adjust dosages of all medications as indicated by glomerular filtration rate.
- Rigorous control of blood pressure, diabetes, and cholesterol.
- Relieve any sources of chronic obstruction.

DISPOSITION

With AIN:

- Complete recovery with return to baseline creatinine occurs in 60% to 65% of cases.
- Partial recovery is seen in 10% to 20%.
- Irreversible damage in 5% to 10%.
- Relapse is common with repeated exposure to offending agents.

REFERRAL

Renal consultation is often necessary, especially if the diagnosis is unclear, biopsy is required, or there is treatment-resistant disease.

PEARLS & CONSIDERATIONS

COMMENTS

Acute interstitial nephritis is most often due to drugs started in the preceding 30 days. The most common drug classes are beta-lactam antibiotics, NSAIDs, and proton pump inhibitors (PPIs). In contrast to ATN, which is often associated with oliguria, early AIN may be associated with polyuria; therefore, a high index of suspicion in this clinical setting is essential for early diagnosis.

PREVENTION

Use known offending agents with care, especially in the elderly and those with known underlying kidney disease.

BASIC INFORMATION

DEFINITION

Provided that criteria for right bundle branch block (RBBB), left bundle branch block (LBBB), or hemifascicular block (Fig. E1) are not met, intraventricular conduction delay (IVCD) is defined by a QRS >110 ms in adults, >90 ms in children 8 to 16 yr, and >80 ms in children younger than 8 yr. It is a common clinical abnormality related to a conduction disturbance that occurs at various levels in the His-Purkinje system. Abnormal activation of the local myocardium can coexist. It can be caused by anatomic abnormalities and the physiologic properties of cardiac tissue. It may occur between ventricles (interventricular), within Purkinje fibers or ventricular myocardium (intraventricular), or between layers of the myocardium (intramural). Parietal block occurs in the terminal Purkinje system and presents with prolonged QRS in leads V1 to V3 compared with V4 to V6. This particular type of IVCD is associated with right ventricular arrhythmogenic dysplasia. It is considered to take place beyond the Purkinje myocardial gates and is due to an abated cell-to-cell conduction.

SYNONYMS

IVCD
Nonspecific/unspecified intraventricular conduction disturbance
Intraventricular conduction delay/defect/block
Fragmented QRS complex
Prolonged/wide QRS

ICD-10CM CODES

I45.4 Non-specific intraventricular block
I45.8 Other specified conduction disorders
I45.9 Conduction disorder, unspecified

EPIDEMIOLOGY

- The prevalence of IVCD in the general population increases with age.
- A Finnish Social Security study, on 10,899 subjects with baseline ECGs, showed a prevalence of IVCD in 0.6% of the total population. 45.6% of subjects with QRS ≥110 ms without evidence of cardiac disease or bundle branch block, had an increased risk of all-cause mortality with relative risk 1.75.
- IVCD has a consensus prevalence of 30% in patients with heart failure (HF) ranging between 14% and 47% in various studies.
- The reported prevalence in military aviators was similar to RBBB at 0.2%.

ETIOLOGY

IVCD is usually the result of abnormal ventricular activation caused by delay in one or more levels of the conduction system. Activation abnormalities of the local myocardium can coexist and further alter the pattern of ventricular excitation.

Patients with IVCD are not a homogeneous group but rather reflect the underlying causative conditions such as dilated cardiomyopathy, hypertensive cardiomyopathy, ischemic cardiomyopathy, or other conditions. Therefore grouping patients on the basis of IVCD is not clinically meaningful.

The most common clinical conditions associated with IVCD are the following:

- Coronary artery disease
- Infiltrative cardiomyopathy: Amyloidosis, sarcoidosis, hemosiderosis, etc.
- Cardiomyopathies of other etiologies
- Left ventricular hypertrophy
- Endocarditis of the aortic valve
- Myocarditis
- Chagas disease (parasitic)
- Primary conduction diseases: Lenegre disease, Lev disease
- Congenital anomalies
- Progressive systemic scleroderma
- Pulmonary embolism
- Cyclic antidepressants
- Hyperkalemia
- Hypothermia
- Intracardiac catheter manipulation

Antiarrhythmic drugs, class IA (e.g., procainamide, disopyramide, quinidine), and class IC (e.g., flecainide, encainide, and propafenone), amantadine, carbamazepine, cocaine, diphenhydramine, mesoridazine, and thioridazine may cause IVCD. In addition, propoxyphene and propranolol can also cause IVCD by sodium channel blockade in older adults due to myocardial fibrosis caused by apoptosis.

Etiology can be unknown in many cases.

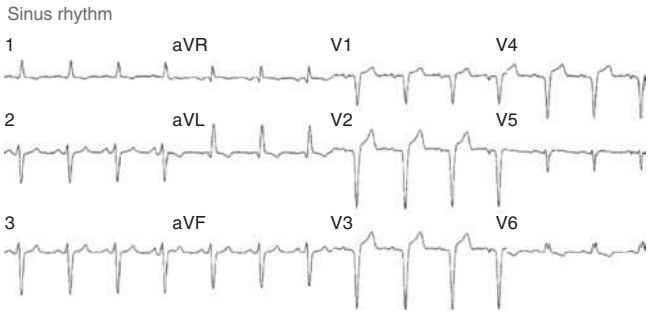

FIG. E1 Normal sinus rhythm baseline with intraventricular conduction delay resembling left bundle branch block (LBBB). *aVF,* Augmented vector foot; *aVL,* augmented vector left; *aVR,* augmented vector right. (From Issa ZF: *Clinical arrhythmology and electrophysiology: a companion to Braunwald's heart disease,* ed 2, Philadelphia, 2012, Saunders.)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

IVCD per se is asymptomatic and is recognizable only with a 12-lead ECG.

DIAGNOSIS

Intraventricular conduction delay is usually an incidental ECG finding. By definition, this defect does not meet criteria for RBBB, LBBB, or hemifascicular block.

DIFFERENTIAL DIAGNOSIS

- Unifascicular block
- Bifascicular block
- Wolff-Parkinson-White (WPW) pattern and variants
- LBBB
- RBBB

EVALUATION

The evaluation of the patient with IVCD should be oriented toward the cause of the ECG abnormality to implement appropriate therapy and counseling. Thorough history and physical exam must be performed to implement adequate laboratory and imaging testing based on the level of suspicion for the causes of IVCD listed earlier. Such tests could include but are not limited to:

- Standard laboratory testing appropriate for age, gender, and metabolic abnormalities
- Resting ECG
- Exercise ECG, with or without imaging
- Ambulatory ECG
- Echocardiogram
- Specialized studies based on known comorbidities and risk assessment or suspicion of them such as heart failure, myocardial infarction, or cardiomyopathies

TREATMENT

Optimize the treatment of the underlying contributing conditions. In selected patients at risk for sudden cardiac death due to significant coronary artery disease or arrhythmogenic right ventricular dysplasia, appropriate referral should be made.

Although cardiac resynchronization therapy has been effective in reducing clinical events in patients with LBBB, patients with IVCD have not demonstrated similar benefit. In the absence of LBBB, cardiac resynchronization therapy offers no benefit for the management of patients with IVCD. In fact there may be an increased risk of ventricular tachycardia for this group when receiving defibrillator devices with or without cardiac resynchronization.

However, intraventricular dyssynchrony has been found to be directly related to IVCD and to have major implications in the identification of adequate electronic pacing sites in patients who require device implantation therapy.

PROGNOSIS

Different studies have shown that IVCD is associated with increased all-cause mortality

with relative risk (RR) 1.75 to 2.01, increased cardiac mortality with RR 1.87 to 4.25, and a markedly elevated risk of sudden arrhythmic death with RR 2.9 to 3.11. A Finnish study in a community cohort, published in 2015, showed that IVCD had a notably high hazard ratio for cardiovascular mortality at 4.25 (95% CI 1.95 to 9.26).

Prognosis depends on the underlying associated clinical conditions. The presence of IVCD constitutes a prognostic marker for cardiac events in CAD, hypertrophic cardiomyopathy, structural heart disease with implanted cardiac defibrillators, Chagas disease, arrhythmogenic right ventricular dysplasia, Brugada syndrome, and acquired long QT syndrome. It is associated with heart failure hospitalization in patients with hypertrophic cardiomyopathy.

An area of increasing interest is the presence of intra- and interatrial conduction delay as it relates to the generation of atrial fibrillation. It is more reliable than left atrial volume and dimension in the prediction of atrial fibrillation and ischemic stroke. It has a direct correlation with aortic strain in patients with hypertension, and it correlates with increased symptoms and mortality in patients with systolic heart failure.

REFERRAL

Refer to a cardiologist if there is history of palpitations, dizziness, heart failure, myocardial infarction, or an abnormal cardiac exam.

PEARLS & CONSIDERATIONS

- IVCD can be due to drugs such as Class I antiarrhythmic drugs.
- IVCD can be a normal variant and is not always associated with cardiac pathology.
- Clinical correlation is needed to identify associated cardiac abnormalities.
- In patients with heart failure, cardiac resynchronization for IVCD in the absence of LBBB is not associated with clinical benefit.

Irritable Bowel Syndrome PTG ALG

BASIC INFORMATION

DEFINITION

Irritable bowel syndrome (IBS) is a chronic functional disorder manifested by alteration in bowel habits and recurrent abdominal pain and bloating. IBS is a symptom complex influenced by a variety of physiologic determinants from gut to brain and back. The ROME IV criteria for diagnosis of IBS are:

- Patient has recurrent abdominal pain ≥1 day per wk, on average, in the previous 3 mo, with an onset ≥6 mo before diagnosis
- Abdominal pain is associated with at least two of the following three symptoms:
  1. Pain related to defecation
  2. Change in frequency of stool
  3. Change in form (appearance) of stool
- Patient has none of the following warning signs:
  1. Age ≥50 yr, no previous colon cancer screening, and presence of symptoms
  2. Recent change in bowel habit
  3. Evidence of overt GI bleeding (e.g., melena or hematochezia)
  4. Nocturnal pain or passage of stool
  5. Unintentional weight loss
  6. Family history of colorectal cancer or inflammatory bowel disease
  7. Palpable abdominal mass or lymphadenopathy
  8. Evidence of iron-deficiency anemia on blood testing
  9. Positive test for fecal occult blood
- The criteria must be fulfilled for at least the past 3 mo with symptom onset at least 6 mo before the diagnosis.
- Table 1 subtypes IBS by predominant stool pattern.

SYNONYMS

Irritable colon
Spastic colon
IBS

ICD-10CM CODES

K58	Irritable bowel syndrome
K58.9	Irritable bowel syndrome without diarrhea
K58.0	Irritable bowel syndrome with diarrhea

EPIDEMIOLOGY & DEMOGRAPHICS

- IBS is the most common functional bowel disorder. An estimated 15 million people in the U.S. have IBS.
- IBS occurs in 7% to 21% of the general population of industrialized countries and is responsible for >50% of gastrointestinal (GI) referrals. Worldwide adult prevalence is 12%. Incidence increases during adolescence and peaks in third and fourth decades of life.
- Female:male ratio is 2:1. Peak prevalence is from 20 to 39 yr of age.
- Nearly 50% of patients have psychiatric abnormalities, with anxiety disorders being most common.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The clinical presentation of IBS consists of abdominal pain and abnormalities of defecation, which may include loose stools, usually after meals and in the morning, alternating with episodes of constipation.
- Physical examination is generally normal.
- Nonspecific abdominal tenderness and distention may be present.

ETIOLOGY

- Unknown, believed to be multifactorial. Fig. 1 illustrates a biopsychological model of IBS pathophysiology
- Associated pathophysiology includes altered GI motility, alteration in gut flora, and increased gut sensitivity
- Risk factors: Anxiety, depression, personality disorders, history of childhood sexual abuse, and domestic abuse in women

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inflammatory bowel disease (IBD)
- Diverticulitis
- Colon malignancy
- Endometriosis
- Peptic ulcer disease
- Biliary liver disease
- Chronic pancreatitis
- Constipation caused by medications (opiates, calcium channel blockers, anticholinergics)
- Diarrhea caused by medications (metformin, colchicine, proton pump inhibitors, antacids, antibiotics)
- Small-bowel overgrowth
- Celiac disease
- Parasites
- Lymphoma of GI tract
- Pelvic floor dyssynergia

TABLE 1 Subtyping Irritable Bowel Syndrome by Predominant Stool Pattern

- IBS with constipation (IBS-C)—hard or lumpy stools* ≥25% and loose (mushy) or watery stools† ≥25% of bowel movements‡
- IBS with diarrhea (IBS-D)—loose (mushy) or watery stools† ≥25% and hard or lumpy stool* ≥25% of bowel movements‡
- Mixed IBS—hard or lumpy stools* ≥25% and loose (mushy) or watery stools† ≥25% of bowel movements‡
- Unsubtyped IBS (IBS unclassified)—insufficient abnormality of stool consistency to meet criteria for IBS with constipation, diarrhea, or mixed‡

IBS, Irritable bowel syndrome.
*Bristol Stool Form Scale 1-2 (separate hard lumps like nuts [difficult to pass] or sausage-shaped but lumpy).
†Bristol Stool Form Scale 6-7 (fluffy pieces with ragged edges, a mushy stool or watery, no solid pieces, entirely liquid).
‡In the absence of use of antidiarrheals or laxatives.
Adapted from Sayuk GS, Gyawali CP: Irritable bowel syndrome: modern concepts and management options, *Am J Med* 128(8):817-827, 2015.

WORKUP

Diagnostic workup (Table 2) is aimed primarily at excluding the conditions listed in the differential diagnoses. A step-wise approach is critical. It is important to identify red flags of other diseases, such as weight loss, rectal bleeding, onset in patients >50 yr, fever, nocturnal pain, and family history of malignancy or IBD. Additional red flags include abnormal examination (e.g., mass, enlarged lymph nodes, stool positive for occult blood, muscle wasting) and abnormal laboratory values (anemia, leukocytosis, abnormal chemistry).

LABORATORY TESTS

- Blood work is generally normal. CBC is reasonable to evaluate for anemia. The presence of anemia should alert to the possibility of a colonic malignancy or IBD.
- Other reasonable tests include C-reactive protein, tissue transglutaminase antibody (rule out celiac disease) and TSH (rule out thyroid abnormalities).
- Fecal calprotectin level is useful to differentiate IBS from inflammatory bowel disease in patients who have IBS with diarrhea or with both diarrhea and constipation. Fecal calprotectin levels less than 40 mcg/g exclude IBD in patients with IBS.
- Testing of stool for ova and parasites should be considered only in patients with chronic diarrhea. Evaluation of stool for *Clostridium difficile* may be helpful in patients with predominant diarrhea symptoms who have recently taken antibiotics.

IMAGING STUDIES

- Imaging studies (e.g., flat and upright abdominal radiograph, small-bowel series, sonogram or CT of abdomen and pelvis) are normal and not necessary for diagnosis.
- Lower endoscopy is generally normal except for the presence of some spasms. Colonoscopic imaging should be performed only in persons who have alarm features to rule out organic disease and in persons older than 50 yr to screen for colorectal cancer.

TREATMENT

NONPHARMACOLOGIC THERAPY

- The patient should be encouraged to maintain an adequate fiber intake and to eliminate foods that aggravate symptoms. Avoidance of caffeine, dairy products, fatty foods, and dietary excesses is also helpful. Several clinical trials have shown that a diet low in fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMAPs) improves symptoms in nearly 70% of patients with IBS.
- Cognitive-behavioral therapy is also recommended, particularly in younger patients because psychosocial stressors are important triggers of IBS. Reassurance that the disorder is benign and education about trigger avoidance and stress management are important.
- Importance of regular exercise and adequate fluid intake should be stressed.

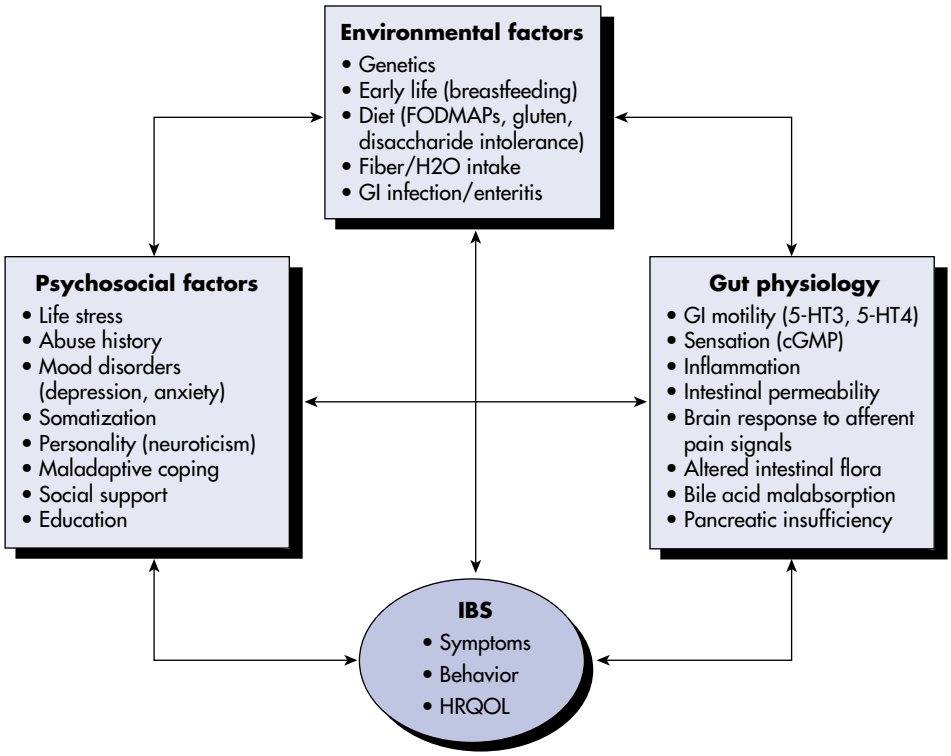

FIG. 1 A biopsychosocial model of irritable bowel syndrome pathophysiology. Irritable bowel syndrome is thought to be a multifactorial disorder, deriving from a potential multitude of etiopathogenic factors, including environmental, psychological, and physiologic factors. This model highlights the complex, often bidirectional interplay of these factors in the experience of irritable bowel syndrome symptoms. *cGMP,* Cyclic guanosine monophosphate; *5-HT3,* serotonin type 3; *5-HT4,* serotonin type 4; *FODMAPS,* fermentable oligosaccharides, disaccharides, monosaccharides, and polyols; *HRQOL,* health-related quality of life; *IBS,* irritable bowel syndrome. (Modified from Sayuk GS, Gyawali CP: Irritable bowel syndrome: modern concepts and management options, *Am J Med* 128(8):817-827, 2015.)

- Fig. E2 illustrates the management of irritable bowel syndrome.

GENERAL Rx

- The mainstay of treatment of IBS is a high-fiber diet. Fiber is helpful for relief of constipation but not for relief of pain. Because symptoms are chronic, the use of laxatives should generally be avoided.
- Soluble fiber (psyllium) is more effective in symptom relief than insoluble fiber (bran). Fiber supplementation with psyllium 1 tbsp bid or calcium polycarbophil (FiberCon) 2 tablets one to four times daily followed by 8 oz of water may be necessary in some patients.
- Patients should be instructed that there might be some increased bloating on initiation of fiber supplementation, which should resolve within 2 to 3 wk. It is important that patients take these fiber products on a regular basis and not only as needed. Fiber is not effective in patients with diarrhea-predominant IBS and may worsen symptoms in these patients.
- Patients who appear anxious can benefit from use of sedatives or selective serotonin reuptake inhibitors (SSRIs). Tricyclic antidepressants in low doses are also effective in some patients with diarrhea-predominant IBS.
- C-2 chloride channel activators: Lubiprostone (Amitiza) is a chloride channel activator that stimulates chloride-rich intestinal fluid secretion and accelerates small intestine and colonic transmit time. It may be effective in chronic constipation-predominant IBS unresponsive to conventional treatment. Usual dose is 8 to 24 mcg bid with food. Side effects include headache and nausea.
- Linaclotide (Linzess) is a guanylate cyclase-C (GC-C) agonist FDA approved for IBS with constipation. It stimulates secretion of chloride and bicarbonate into the intestinal lumen, mainly through activation of the CFTR ion channel, resulting in increased intestinal fluid and accelerated transit. Usual dose for IBS is 290 mcg 30 min before eating. The most common adverse effects are diarrhea, abdominal pain, flatulence, and abdominal distension.
- Eluxadoline (Viberzi) is a μ-opioid receptor agonist and Δ-opioid receptor antagonist FDA approved for IBS with diarrhea. It decreases muscle contractility, inhibits water and electrolyte secretion, and increases rectal sphincter tone. Usual dose is 100 mg PO bid taken with food.
- Loperamide is effective for diarrhea. Alosetron, a serotonin type-3 receptor antagonist previously withdrawn because of severe constipation and ischemic colitis, has been reintroduced with limited availability. It is indicated only for women with severe chronic diarrhea-predominant IBS unresponsive to conventional therapy and not caused by anatomic or metabolic abnormality. Starting dose is 1 mg qd.
- Alterations in gut flora have been identified as potentially contributing to IBS (84% of IBS patients have an abnormal lactulose breath test, suggesting small-intestinal bacterial overgrowth). Rifaximin, a gut-selective antibiotic, has been used in recent trials to eradicate bacterial overgrowth (70% eradication rate). A dose of 400 mg tid for 10 days was reported effective in improving IBS symptoms up to 10 wk after discontinuation of therapy. Until additional evidence is available, use of rifaximin or other antibiotics in IBS should be reserved for patients with proven bacterial overgrowth.
- Antispasmodics-anticholinergics (e.g., dicyclomine, hyoscyamine) are often used, but efficacy data from clinical trials are inconclusive.
- Probiotics: Bifidobacteria and some combinations of probiotics have shown some limited efficacy. Lactobacilli do not appear to be

TABLE 2 Irritable Bowel Syndrome Treatment Strategy: A Way Forward

1. Evaluation
   a. Consider conditions that mimic IBS (e.g., celiac disease, microscopic colitis, bile acid diarrhea, pancreatic insufficiency, carbohydrate intolerances, medication side effects, postsurgical neoanatomy)
   b. Assess for the presence of alarm symptoms
   c. Evaluate for symptom triggers (e.g., stressors, diet)
   d. Explore presence of other functional GI (e.g., functional dyspepsia) and non-GI disorders (e.g., fibromyalgia), psychiatric comorbidity, and drug intolerances
   e. Understand previous IBS treatment experiences
2. Selection of treatment approach
   a. Predicated on symptom severity and dominant symptoms
   b. Symptom severity (intensity, bother, effects on quality of life)
      i. Mild symptoms, intermittent symptoms, low symptom burden: Symptomatic or peripheral therapy
      ii. Moderate symptoms: Centrally acting neuromodulators, especially if symptomatic therapy does not provide adequate benefit
      iii. Severe symptoms and those with comorbidities (non-GI functional disorders, psychiatric): Both centrally acting neuromodulators and peripheral therapy
         a. Concurrent affective disorders need to be managed.
         b. Other central therapies (cognitive and behavioral therapy, hypnosis, stress reduction) may need to be considered.
   c. Dominant symptoms (diarrhea, constipation, pain, other GI symptoms)
      i. Constipation predominant
         a. Laxatives, fiber
         b. Novel agents (linaclotide, lubiprostone)
      ii. Diarrhea predominant
         a. Antidiarrheals
         b. Alosetron
         c. Address dysbiosis (rifaximin, probiotics)
         d. Diet (low FODMAP)
         e. Bile binders (cholestyramine, colesevelam)
         f. Disaccharidases (lactase)
      iii. Pain predominant
         a. Antidepressants (TCAs and SNRIs preferred)
         b. Linaclotide when constipation present
         c. Avoid narcotics
3. Education and therapeutic alliance
   a. Inform patient about etiopathogenesis.
   b. Reaffirm legitimacy of diagnosis; allay concerns about organic disease.
   c. Provide information about support organizations (International Foundation for Functional Gastrointestinal Disorders).

FODMAP, Fermentable oligosaccharides, disaccharides, monosaccharides, and polyols; *GI,* gastrointestinal; *IBS,* irritable bowel syndrome; *SNRI,* serotonin-norepinephrine reuptake inhibitor; *TCA,* tricyclic antidepressant.

effective for the treatment of IBS. Additional data showing efficacy is needed before probiotics can be endorsed for treatment of IBS.

- Antidepressants: SSRIs are more effective than placebo for relief of global IBS symptoms.

DISPOSITION

More than 60% of patients respond successfully to treatment over the initial 12 mo; however, IBS is a chronic, relapsing condition and requires prolonged therapy.

REFERRAL

GI referral is recommended in patients with rectal bleeding, fever, nocturnal diarrhea, anemia, weight loss, or onset of symptoms >40 yr. Consultation is also necessary if specialized diagnostic procedures such as endoscopy are necessary.

PEARLS & CONSIDERATIONS

COMMENTS

- Patients should be educated regarding maintenance of a high-fiber diet and elimination of stressors, which can precipitate attacks of IBS. They should be reassured that their condition does not lead to cancer.
- Recent drug efforts (alosetron, tegaserod) are aimed at serotonergic receptors in the gut because most of the serotonin in the body is found in the GI tract and is believed to be involved in the mediation of visceral sensation and motility.
- Cognitive-behavioral therapy is effective in the treatment of patients with IBS and should be considered as part of the armamentarium against this disorder.
- Some patients with IBS but without celiac disease show symptom improvement on a wheat-free diet. A 2- to 3-wk trial of wheat avoidance may be reasonable in patients with treatment-resistant IBS.

BASIC INFORMATION

DEFINITION

Ischemic colitis (IC) is tissue damage and inflammation of the large intestine due to a reduction in blood flow.

SYNONYMS

Intestinal ischemia
Colonic ischemia
IC

ICD-10CM CODES

K51.50	Left-sided colitis without complications
K51.51	Left-sided colitis with complications
K51.511	Left-sided colitis with rectal bleeding
K51.512	Left-sided colitis with intestinal obstruction
K51.513	Left-sided colitis with fistula
K51.514	Left-sided colitis with abscess
K51.518	Left-sided colitis with other complication
K51.519	Left-sided colitis with unspecified complications
K52.3	Indeterminate colitis
K55.0	Acute vascular disorders of intestine
K55.031	Focal (segmental) acute (reversible) ischemia of large intestine
K55.032	Diffuse acute (reversible) ischemia of large intestine
K55.039	Acute (reversible) ischemia of large intestine, extent unspecified
K55.9	Vascular disorder of intestine, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: It is the most common type of intestinal ischemia with an annual incidence of 15.6 to 17.7 per 100,000.
PEAK INCIDENCE: Unknown
PREVALENCE: Unknown
PREDOMINANT SEX AND AGE:
- More common among older patients (60s to 70s)
- Female predominance

RISK FACTORS:
- Older age (60s to 70s)
- Atherosclerotic disease
- Hemodialysis
- Hypertension
- Atrial fibrillation
- Diabetes
- Small vessel disease
- Sickle cell disease
- Infection (CMV, *E. coli*)
- Aortic surgery, endovascular intervention, cardiopulmonary bypass surgery
- Long-distance running, extreme exercise
- Hypercoagulable state
- Myocardial ischemia
- Mechanical obstruction
- Hypoalbuminemia
- Pharmacologic
- Shock

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Key historical points:
  1. Rapid-onset cramping and abdominal pain (classically thought to involve the left side more often, but newer literature suggests that no one region is affected predominantly). Pain secondary to large intestine ischemia is often not as severe as pain associated with small intestine ischemia
  2. Urge to defecate may accompany developing abdominal pain
  3. Hematochezia (usually within 24 hrs). More commonly associated with ischemic colitis of the large bowel compared with small bowel involvement
- Physical exam findings suggestive of ischemic colitis:
  1. Abdominal exam may be nonspecific early on
  2. May have peritoneal signs in severe illness or bowel perforation
  3. Hypotension and tachycardia in severe cases
  4. Guaiac positive stool

ETIOLOGY

GENERAL:
- Caused by a reduction in blood flow, usually sudden, to a segment of the large intestine. The resulting blood flow is not enough to provide the oxygen and nutrients necessary for normal cellular metabolism.
- Particularly affected are the watershed regions of the colon (Fig. E1), which have limited collateral circulation (splenic flexure and sigmoid colon).
- Medical and surgical conditions associated with ischemic colitis are summarized in Box 1.

SPECIFIC:
- Nonocclusive disease:
  1. Hypoperfusion: Cardiac failure, septic shock, hemorrhagic shock, hemodialysis
  2. Iatrogenic: Drugs (especially constipation-inducing). Medications associated with ischemic colitis are summarized in Box 2
  3. Colonic obstruction: Colon cancer, constipation, volvulus
  4. Long-distance running
- Occlusive disease:
  1. Arterial: Thrombus/emboli, cholesterol emboli, small vessel disease (atherosclerosis, diabetes, vasculitis, rheumatoid arthritis, radiation, amyloidosis), trauma
  2. Surgical: Aortic aneurysm repair, cardiac catheterization, cardiopulmonary bypass, colectomy, endoscopy, renal transplant
  3. Venous: Mesenteric venous thrombosis, hypercoagulable state, sickle cell disease, pancreatitis, portal hypertension, lymphocytic phlebitis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious colitis (e.g., *Clostridium difficile, Salmonella, Shigella*)

BOX 1 Medical and Surgical Conditions Associated with Ischemic Colitis

Cardiovascular/Pulmonary
Atherosclerosis*
Atrial fibrillation
Chronic obstructive pulmonary disease
Hypertension

Gastrointestinal
Constipation
Diarrhea
Irritable bowel syndrome

Low Flow State
Septic shock
Congestive heart failure
Hemorrhagic shock
Hypotension

Surgery
Abdominal surgery
Aortic surgery
Cardiovascular surgery

Invasive Interventions
Postendovascular abdominal manipulations (e.g., chemoembolization)
Postcolonoscopy

Metabolic/Rheumatoid
Diabetes mellitus
Dyslipidemia
Rheumatoid arthritis
Systemic lupus erythematosus

Miscellaneous
Hypercoagulable states†
Sickle cell disease
Long-distance running

*For example, ischemic heart disease, cerebrovascular disease, peripheral vascular disease.
†Antiphospholipid syndrome, factor V Leiden deficiency, protein C and S deficiency.
From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

BOX 2 Drugs Associated with Ischemic Colitis

Constipation-inducing drugs (opioids and nonopioids)
Immunomodulator drugs (anti-TNFα, type 1 interferon-α, type 1 interferon-β)
Chemotherapeutic drugs (e.g., Taxanes)
Cocaine and methamphetamines
Female hormones
Oral contraceptive medications
Antibiotics
Pseudoephedrine
Serotoninergic (e.g., Alosetron, Sumatriptan)
Diuretics

TNF, Tumor necrosis factor.
From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

- Inflammatory bowel disease, inflammatory bowel syndrome, celiac disease
- Small bowel ischemia
- Constipation
- Diverticulitis
- Bowel obstruction
- Pancreatitis
- Malignancy
- Radiation enteritis

WORKUP

The clinical presentation is often vague and can be variable from patient to patient. A high index of suspicion must be maintained in any patient presenting with abdominal pain and bloody stool. In addition to the physical exam, the following are key to confirming the diagnosis:

- Lab studies
- Computed tomography
- Lower endoscopy

LABORATORY TESTS

- General:
  1. CBC (may see leukocytosis)
  2. Metabolic panel
  3. Liver function panel
- Specific markers: There are no specific laboratory tests for ischemic colitis. However, elevated levels of certain markers suggest inadequate global perfusion:
  1. Lactate
  2. Lactate dehydrogenase
  3. CK
  4. Amylase
- Coagulation studies
- Stool studies: Stool culture, ova and parasite, *C. difficile* toxin assay, tests for *Salmonella, Shigella, Campylobacter,* and *E. coli*

IMAGING STUDIES

- Abdominal CT with contrast: Although findings can be nonspecific, the value of CT is in distinguishing ischemic colitis from nonischemic causes of abdominal pain. It also can assess the degree of ischemia and gauge the need for surgical intervention. It may identify arterial emboli or venous obstruction. Specific findings suggestive of ischemic colitis include, but are not limited to, intestinal wall thickening, thumbprinting, pericolonic stranding, and peritoneal free fluid or free air. Pneumatosis (the presence of gas in the colonic wall), portal venous gas, and the presence of megacolon usually indicate severe disease favoring immediate surgical intervention.
- Abdominal radiograph: X-rays are rarely helpful in diagnosing ischemic colitis. Findings may be subtle or absent unless transmural necrosis and perforation have occurred, causing pneumoperitoneum.
- Lower endoscopy: This is the gold standard for confirming diagnosis of ischemic colitis. In the absence of peritoneal signs, colonoscopy is the test of choice to evaluate the degree of ischemia. If ischemia is suspected, lower endoscopy should be performed within the first 24 to 48 hrs. In most cases, visual inspection of the colonic wall using this technique will confirm the diagnosis and dictate the need for conservative versus surgical management. However, endoscopy should not be performed in patients with acute peritonitis or evidence of irreversible ischemic damage on CT.

Rx TREATMENT

- Treatment depends on the severity of disease and the specific etiology of colonic ischemia. However, the mainstay of therapy consists of optimizing blood flow to ischemic regions of bowel and removing any potential exacerbating factors. Initial supportive care consists of aggressive IV crystalloid resuscitation, bowel rest, and broad-spectrum antibiotics with aerobic and anaerobic coverage. A treatment algorithm is illustrated in Fig. 2.
- In mild cases where patients are hemodynamically stable and do not have signs of peritonitis, colonoscopy should be performed. Patients with nonviable bowel seen on endoscopy require immediate operative intervention. However, the remainder of patients should be managed medically with continued IV fluids, bowel rest, and broad-spectrum antibiotics. Consider the use of a nasogastric tube in patients with abdominal distention or signs of ileus or bowel obstruction. Avoid vasoconstrictive medications as these can exacerbate colonic hypoperfusion. Monitor signs of adequate end organ perfusion (e.g., mental status, abdominal pain, urine output). Management of underlying causes (e.g., heart failure, vascular disease, sepsis) should be considered.
- In severe cases not responding to supportive therapy, where patients are exhibiting acute peritonitis, sepsis, hypotension, or pain out of proportion to clinical exam, surgical abdominal exploration is warranted. Resection of gangrenous segments of bowel may be necessary. Colonoscopy should be avoided in these patients.

NONPHARMACOLOGIC THERAPY

- Open or laparoscopic abdominal exploration to identify necrotic bowel. Box 3 summarizes indications for surgical intervention in patients with ischemic colitis
- NG tube for bowel decompression if ileus is present

ACUTE GENERAL Rx

- Supportive care:
  1. IV fluids
  2. Bowel rest
  3. Broad-spectrum antibiotics (aerobic and anaerobic coverage)
- Anticoagulation (not indicated in nonocclusive ischemia but may be considered in proven arterial occlusion or mesenteric vein thrombosis)
- Abdominal exploration:
  1. Bowel prep should be given
  2. Bowel resection may be indicated in severe colitis
  3. Repeat surgical exploration normally is performed within 12 to 24 hrs, especially after colonic resection, to assess the viability of colonic tissue and state of the anastomosis. Intraoperative infrared angiography based on IV injection of indo cyanine green (Fig. E3) can be used as an adjunct for decisions of whether to resect in determining margins and the integrity of intestinal anastomoses
  4. Note that primary anastomosis after colonic resection is contraindicated in certain cases (e.g., presence of aortic or iliac grafts; or when tissue is too friable for stable anastomosis)

CHRONIC Rx

- Avoid overly aggressive hypertension treatment.
- Avoid dehydration.
- Avoid extreme exercise.

DISPOSITION

- Most cases of acute ischemic colitis are nongangrenous and resolve completely with medical care in 1 to 2 days. However, the need for surgery in more severe cases portends a worse prognosis and is associated with increased morbidity and mortality. Any risk factors for ischemic colitis should be identified and mitigated as much as possible.

REFERRAL

Prompt general surgery consultation is indicated in patients with the following:

- Hemodynamic instability and peritoneal signs on examination
- CT showing signs of bowel infarction or perforation
- Endoscopy showing nonviable bowel or peritoneal signs

PEARLS & CONSIDERATIONS

COMMENTS

Ischemic colitis typically occurs in older patients who have multiple comorbidities. A high index of suspicion should be maintained for patients with recent endovascular procedures. These patients require close outpatient follow-up and management by a primary care provider.

PREVENTION

Avoid overly aggressive hypertension treatment, dehydration, and extreme exercise.

Ischemic Hepatitis

BASIC INFORMATION

DEFINITION

- A common form of vascular liver disease
- Occurs when a severe systemic disturbance leads to decreased perfusion to the liver resulting in tissue hypoxia

SYNONYMS

Hypoxic hepatitis
Shock liver
Ischemic hepatopathy
Hepatic necrosis

ICD-10CM CODES

K76.2	Central hemorrhagic necrosis of liver
K75.89	Other specified inflammatory liver disease

EPIDEMIOLOGY & DEMOGRAPHICS

- Occurs worldwide

INCIDENCE:

- Less than 1% on the inpatient medical wards
- Incidence is higher (2.5%) in intensive care unit

PEAK INCIDENCE: Highest in the cardiac care units

PREVALENCE:

- Recognized as most frequent cause of acute liver injury
- 57% of patients with liver enzymes >1000 IU/L have ischemic hepatitis
- Prevalence up to 10% in the intensive care setting

PREDOMINANT AGE AND SEX:

- Can occur in all ages
- Most common in elderly

GENETICS: No genetic predisposition

RISK FACTORS:

- Most common is cardiovascular disease
- Chronic heart failure
- Cirrhosis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Altered mental status may be present due to decreased cerebral perfusion.
- Other symptoms are often masked by the overall disease state.
- Hepatic synthetic function is usually preserved in ischemic hepatitis.

ETIOLOGY

- Cardiac disease in the most common (Fig. E1)
- This includes myocardial infarction, arrhythmias, cardiac tamponade, and cardiogenic shock
- Majority of patients have markedly increased cardiac filling pressures
- Respiratory failure and sepsis are the second and third most common
- Hypovolemic shock from hemorrhage, dehydration, and heat stroke
- Hypotension (only 1 in 2 patients have documented low blood pressures)
- See Table 1 for a brief summary of the different causes of ischemic hepatitis

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS (TABLE 2)

- Acute viral hepatitis
- Autoimmune hepatitis
- Drug-induced liver injury
- Other toxins and medications (i.e., acetaminophen toxicity)

WORKUP

- Diagnosed by laboratory parameters and the clinical context of a hospitalized patient.
- Workup is directed at identifying the predisposing cause.
- Liver biopsy is not required.
- Histology shows centrilobular (zone 3) necrosis with preservation of the hepatic architecture.
- Necrosis can extend to the midzonal hepatocytes in the setting of prolonged ischemia.

LABORATORY TESTS

- Extremely elevated aminotransferase levels, often exceeding 200 times the upper limit of normal.
- Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) rapidly rise after the ischemic insult.
- They peak within 1 to 3 days.
- They usually return to normal within 7 to 10 days if the initial ischemic insult is resolved.
- Lactate dehydrogenase (LDH) level is extremely elevated.
- ALT/LDH ratio of less than 1.5 is suggestive.
- Prothrombin time can be slightly prolonged.
- The serum bilirubin can be mildly increased.
- Serum bilirubin peaks after the aminotransferases peak.
- Increased blood urea nitrogen and creatinine levels from acute tubular necrosis and renal dysfunction.

IMAGING STUDIES

Imaging is not required for the diagnosis.

TREATMENT

NONPHARMACOLOGIC THERAPY

Management is directed at treating the underlying illness causing the systemic disturbance.

ACUTE GENERAL Rx

- Hemodynamic resuscitation
- Inotropic agents for cardiogenic shock
- Intravenous fluid resuscitation with or without vasoconstrictors for septic or hypovolemic shock
- Blood transfusions if hypovolemic shock from blood loss
- These measures optimize hepatic perfusion and resolve tissue hypoxia
- There is no role for *N*-acetylcysteine administration

TABLE 1 Causes of Ischemic Hepatitis

Cardiovascular disease (most common): Cardiogenic shock
Respiratory failure
Sepsis/septic shock
Hypovolemic shock: Hemorrhage, volume depletion
Hypotension

TABLE 2 Common Differentials of Ischemic Hepatitis

Acute viral hepatitis (e.g., hepatitis A, hepatitis B)
Autoimmune hepatitis
Toxins (e.g., herbal supplements)
Medications (e.g., acetaminophen)

CHRONIC Rx

- Ensure stability of underlying illness
- No specific liver-directed therapy

DISPOSITION

- Most commonly a self-limited and benign condition if promptly managed.
- Occasionally associated with significant mortality.
- Prognosis is determined by the severity of the underlying illness. In-hospital mortality associated with ischemic hepatitis is roughly 50%.
- Patients with underlying chronic heart failure or cirrhosis have worse outcomes.
- Other poor prognostic factors include persistently elevated aminotransferase and multiorgan failure.

REFERRAL

- Referral to a hepatologist is not required once illness is resolved.
- Referral is appropriate if patient has underlying cirrhosis.

PEARLS & CONSIDERATIONS

COMMENTS

- Have a high index of suspicion for this diagnosis in a hospitalized patient with severe systemic illness and significantly elevated AST and ALT.
- Use ALT/LDH ratio to aid in the diagnosis.
- Do not be alarmed if bilirubin continues to rise after AST and ALT peak.
- Hypotension is often not documented or not present at all.
- Patients with significantly elevated liver enzymes should be evaluated for occult heart failure.

PREVENTION

Ensure stability of comorbidities (e.g., cardiac disease)

AUTHOR: **Hiresh D. Trivedi, MD**

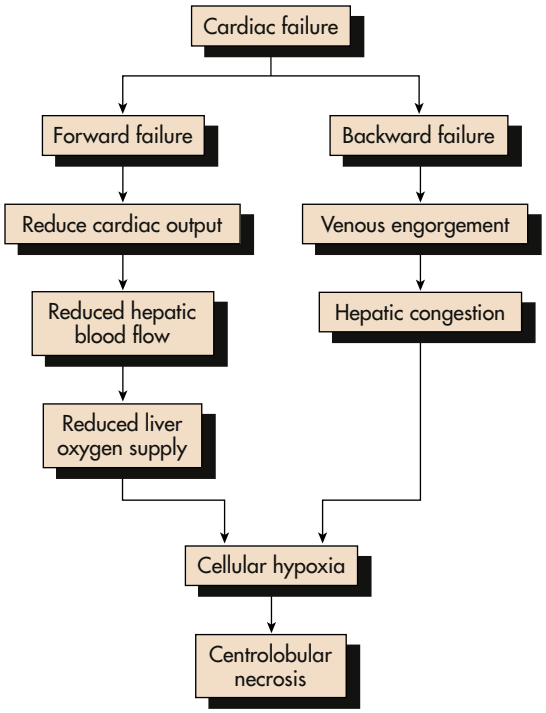

FIG. E1 The most common cause of hypoxic hepatitis is a combination of liver congestion due to chronic cardiac failure and an acute drop in cardiac output causing liver ischemia. (From Parrillo JE, Dellinger RP: *Critical care medicine: Principles of diagnosis and management in the adult,* ed 4, Philadelphia, 2014, Saunders.)

Ischemic Optic Neuropathy

BASIC INFORMATION

DEFINITION

Ischemic optic neuropathy (ION) is a general term for dysfunction of the optic nerve due to decreased blood supply and subsequent neuronal death.

Subclassifications:

- Arteritic anterior ischemic optic neuropathy (AAION)
- Nonarteritic anterior ischemic optic neuropathy (NAION)
- Posterior ischemic optic neuropathy (PION)

SYNONYMS

ION
AAION
NAION
PION

ICD-10CM CODE
H47.01 Ischemic optic neuropathy

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- 2.3 to 10 cases of anterior ischemic optic neuropathy per 100,000 per yr (15% AAION, 85% NAION).
- PION is much less common than anterior ischemic optic neuropathy (AION).

PREDOMINANT AGE, RACE, AND SEX:

- Age >50, though may occur at any age.
- White women are at particular risk of AAION due to giant cell arteritis (GCA).
- 95% of NAION patients are white.

RISK FACTORS:

- NAION: Diabetes mellitus, hypertension, episodic hypotension, obstructive sleep apnea, hypercholesterolemia. Emboli can be refractile yellow-white cholesterol (Hollenhorst) plaques (Fig. E1, *A*), grayish elongated fibrin-platelet aggregates (Fig. E1, *B*), or nonscintillating white calcific particles (Fig. E1, *C*)
- PION: Surgery (hemodilution, prolonged hypotension, orbital edema, and orbital compression), or factors associated with AAION and NAION

CLINICAL PRESENTATION

- AAION: Sudden, unilateral, often painless vision loss. Will commonly have systemic symptoms of GCA including headache, jaw claudication, scalp tenderness, fever, and weight loss, but vision loss may be the only presenting sign/symptom
- NAION: Sudden, unilateral, painless vision loss, often upon awakening
- PION: Sudden, painless loss of vision that is either unilateral or bilateral. Typically bilateral if following surgery or unilateral in its arteritic or nonarteritic form with symptoms similar to AAION and NAION, respectively

PHYSICAL FINDINGS

- All types of ION may result in a relative afferent pupillary defect and/or dyschromatopsia in the affected eye.
- AAION: Severe vision loss with visual acuity worse than 20/200 in a majority of patients. Fundoscopic view of the optic nerve head in the affected eye will show pallid edema ("chalky white" disc).
- NAION: Blurring/cloudiness of vision with relatively preserved central visual acuity (>20/64 in 31% to 52% of patients). Fundoscopic view of the optic nerve head during the acute phase will show edema and surface capillary dilation with peripapillary splinter hemorrhages. The unaffected eye will likely reveal a small cup-to-disc ratio.
- PION: Vision loss is worst in surgical PION, otherwise similar to AAION and NAION. Fundoscopic exam typically normal in acute setting, but may show pallor weeks later.

ETIOLOGY

- AAION: Sudden occlusion of the short posterior ciliary arteries that supply the optic nerve head as a result of vasculitis. The most common vasculitis is GCA, but others include

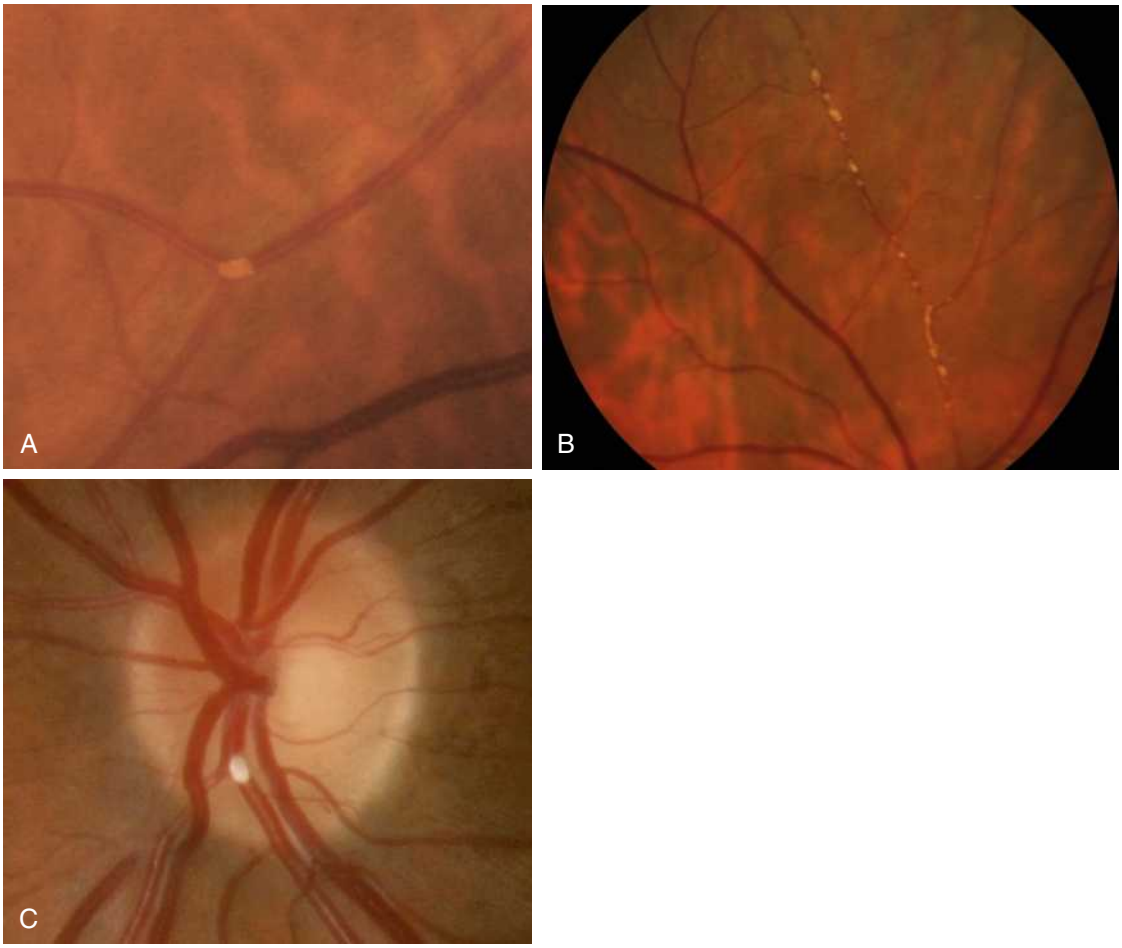

FIG. E1 Retinal emboli. A, Hollenhorst plaque; **B,** fibrin-platelet emboli; **C,** calcific embolus at the disc. (From Bowling B: *Kanski's clinical ophthalmology: a systematic approach,* ed 8, Edinburgh, 2016, Elsevier.)

eosinophilic granulomatosis with angiitis (previously Churg-Strauss syndrome), polyarteritis nodosa, or rheumatoid arthritis.
- NAION: It is hypothesized that hypoxia of the optic nerve head results in slight edema of the axons of the optic nerve. As the edema increases, a compartment syndrome develops resulting in the occlusion of the short posterior ciliary arteries in the optic nerve head.
- PION: Ischemia in the retrobulbar optic nerve due to hypoperfusion of the pial plexus. This may be secondary to either surgery or arteritic/nonarteritic causes as discussed previously.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Optic neuritis: Typically associated with painful vision loss and may be the presenting sign of multiple sclerosis or neuromyelitis optica
- Toxic/nutritional optic neuropathy: Typically bilateral, symmetric, painless, and slowly progressive, although may be acute (such as with methanol or ethylene glycol poisoning)
- Radiation-induced optic neuropathy: Typically develops within 3 yr of radiation to structures near the optic nerve. Progresses within weeks with no recovery of vision
- Infectious optic neuropathy: Optic neuropathy can develop as a result of a number of infections including bacterial (*B. henselae, M. tuberculosis*), spirochetes (*B. burgdorferi, T. pallidum*), fungi (*Cryptococcus* sp., *Aspergillus* sp.), or viruses (cytomegalovirus, Epstein-Barr virus, or varicella-zoster virus in immunocompromised patients)
- Compressive optic neuropathy (e.g., from tumor): Typically progressive vision loss but may present acutely

WORKUP

- Complete history focused on pertinent symptoms and risk factors.
- Workup should focus on excluding GCA (headache, jaw claudication, scalp tenderness, fever), as treatment delay may result in permanent vision loss in both eyes.
- Careful examination of optic disc, look for "chalky white" pallor suggestive of AAION or edema and peripapillary hemorrhages suggestive of NAION.
- The unaffected eye should also be examined and compared.

LABORATORY TESTS

- Complete blood count with C-reactive protein (level above 2.45 mg/dl highly suggestive of GCA) and erythrocyte sedimentation rate
- Tests to rule out infectious optic neuropathy as appropriate

IMAGING STUDIES

- Visual field testing: May detect any visual field defects associated with optic nerve injury (including altitudinal, arcuate, and central visual field defects). PION in particular is associated with central visual field defects.
- Optical coherence tomography: May show swelling of the optic disc.
- Fluorescein angiography: May show generalized choroidal filling delay (AAION) or delayed filling in the optic disc prelaminar layers (NAION). PION will show no abnormalities.

WORKUP

Temporal artery biopsy if high suspicion for GCA.

Rx TREATMENT

- AAION: Treatment should begin as soon as GCA is suspected. Corticosteroids are the mainstay of treatment. Recommendations include either oral prednisone (80-120 mg daily) or intravenous methylprednisolone (1 g daily) for 3 to 5 days followed by 1 to 2 mg/kg/day oral prednisone for 4 to 6 weeks and tapered gradually to 10 to 15 mg/day and maintained for 12 or more months.
- NAION: There is currently no effective treatment for NAION. Proposed treatments that have not been shown to be efficacious include corticosteroids, intravitreal anti-VEGF injections, aspirin, hyperbaric oxygen, and surgical decompression.
- PION: Arteritic and nonarteritic forms of PION should be treated as for AAION, and there is currently not an effective treatment for surgical PION.

DISPOSITION

- AAION: If not treated, the second eye is similarly affected in 50% to 95% of patients. With treatment, contralateral eye involvement is generally prevented and some patients have slight improvement in affected eye.
- NAION: Approximately 20% to 25% will spontaneously recover some vision, and the same amount may have some worsening. Although recurrent NAION in the same eye is not likely (3% to 8%), up to 30% to 40% of patients experience contralateral eye involvement in their lifetime.
- PION: Arteritic/nonarteritic forms as mentioned previously, patients with surgical PION generally have little change following vision loss.

REFERRAL

Recommend referral to an ophthalmologist or neuroophthalmologist for evaluation and workup. Again, if GCA is suspected, begin treatment immediately.

! PEARLS & CONSIDERATIONS

- Ischemic optic neuropathy can be classified as either anterior or posterior, and may be due to arteritic, nonarteritic, or surgical causes.
- Correct identification of the underlying etiology is key to preventing further vision loss, especially in patients with GCA.
- Patients suspected of having GCA should be treated with corticosteroids immediately and undergo temporal artery biopsy within a week of starting corticosteroid treatment.

BASIC INFORMATION

DEFINITION

Jaundice is a yellowish discoloration of the sclera, skin, and mucous membranes caused by an excessive amount of bilirubin in the bloodstream. Clinically detectable jaundice in adults is a serum bilirubin of 2.5 to 3 mg/dl.

SYNONYM

Icterus

ICD-10CM CODE
R17 Unspecified jaundice

EPIDEMIOLOGY & DEMOGRAPHICS

The prevalent causes of jaundice by age and sex:
- Young adulthood (for either sex): Viral hepatitis, Gilbert disease
- Middle adulthood (for either sex): Drug-induced hepatitis and cirrhosis
- Middle-aged and older men: Alcoholic liver disease, pancreatic cancer, hepatoma, primary hemochromatosis
- Women: Primary biliary cirrhosis, chronic active hepatitis, choledocholithiasis, carcinoma of the gallbladder

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Presentation can vary from an incidental finding to acute and life threatening. History and physical examination give important clues to the underlying condition.

Key history of present illness findings:
- Duration of jaundice
- Associated symptoms: Abdominal pain, fever, nausea, malaise, pruritus, chills, changes in urine and stool color, anorexia and/or weight loss

Key social history/exposure findings:
- Alcohol use, injection of illicit drugs, use of hepatotoxic medication or herbal products, blood transfusions, unprotected sex, ingestion of shellfish, travel, occupational exposure to toxins

Key medical history findings:
- Prior abdominal/biliary surgery, prior episodes of jaundice, prior diagnosis of hepatitis B or C, inflammatory bowel disease

Key physical findings:
- Vital sign abnormalities: Fever, hypotension, tachycardia
- Signs of acute disease: Abdominal tenderness, splenomegaly, abdominal mass, encephalopathy, Murphy sign
- Signs of chronic liver disease: Palmar erythema, spider angiomas, bruising, gynecomastia, testicular atrophy, ascites, weight loss, Kayser-Fleischer rings (Wilson), caput medusa, internal hemorrhoids, scleral icterus

ETIOLOGY

Disruption in any of the three phases of bilirubin metabolism can lead to jaundice:
- Prehepatic phase: An increase in heme degradation products from red blood cell catabolism, ineffective erythropoiesis, or breakdown of muscle myoglobin and cytochromes; leads to indirect (unconjugated) hyperbilirubinemia
- Intrahepatic phase: Destruction of the hepatocytes or disruption of either of the two separate biochemical processes that conjugate bilirubin in the hepatocyte; may lead to indirect (unconjugated) or direct (conjugated) hyperbilirubinemia
- Posthepatic phase: Blockage of the release of water-soluble bilirubin from the hepatobiliary system, preventing excretion into the stool or urine or recycling within the gut flora; leads to direct (conjugated) hyperbilirubinemia

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Prehepatic causes:
- Hemolytic processes (e.g., sickle cell disease, spherocytosis, thalassemia, G6PD, immune hemolysis, HUS), ineffective erythropoiesis (e.g., thalassemia, folate, severe iron deficiency), or large hematoma reabsorption

Intrahepatic causes:
- If unconjugated hyperbilirubinemia: Enzyme metabolism disorders (Gilbert disease, Crigler-Najjar syndrome), drugs that alter the enzymatic pathways such as rifampin, isoniazid, and probenecid
- If conjugated hyperbilirubinemia: Intrahepatic cholestasis caused by:
  1. Viruses: Hepatitis A, B, and C; Epstein-Barr, hemorrhagic viruses (yellow fever, Ebola)
  2. Other infections: Bacteria (leptospirosis, MAI), parasites (schistosomiasis, malaria, amebiasis), fungal *(Blastomyces, Histoplasma)*
  3. Alcohol: Alcoholic hepatitis, alcoholic cirrhosis
  4. Autoimmune: Primary biliary cirrhosis, primary sclerosing cholangitis, autoimmune hepatitis
  5. Hepatotoxic drug-induced: Acetaminophen (most common), penicillins (most commonly Augmentin), chlorpromazine, steroids (estrogenic or anabolic), NSAIDs, valproic acid, some herbals such as kava, ma huang, and off-market weight-loss supplements
  6. Hereditary/metabolic: Sickle cell disease and other RBC dyscrasias, hemochromatosis, Wilson disease, Dubin-Johnson and Rotor syndromes, α-antitrypsin deficiency, glycogen storage disease, NASH (nonalcoholic steatohepatitis), porphyria, benign recurrent intrahepatic cholestasis
  7. Systemic disease: Invading liver: Sarcoidosis, amyloidosis, hemochromatosis, tuberculosis, *Mycobacterium avium intracellulare*
  8. Other: Cirrhosis, sepsis, total parenteral nutrition, intrahepatic cholestasis of pregnancy, graft-versus-host disease, environmental toxins, benign postoperative state

Posthepatic causes:
- Intrinsic or extrinsic obstruction of the biliary system:
  1. Blockage within hepatobiliary tree: Strictures, cholangiocarcinoma, gallbladder cancer, carcinoma of ampulla of Vater, infection (e.g., cytomegalovirus, *Cryptosporidium* in patients with AIDS, parasites), choledocholithiasis
  2. Blockage outside of hepatobiliary tree: Pancreatitis, pancreatic carcinoma, pancreatic pseudocyst, lymphoma
- Pseudojaundice: Not related to bilirubin but rather resulting from excessive ingestion of foods containing beta carotene (e.g., carrots, melons, squash)

WORKUP

- History, physical examination, and first-line lab tests can often clarify diagnosis. Fig. 1 describes a clinical approach to jaundice.
- Table 1 summarizes the differential diagnosis of critical and emergent diagnoses in patients with jaundice.

LABORATORY TESTS

- First-line tests:
  1. Serum total and direct bilirubin
  2. Urinalysis
  3. Liver function tests (AST, ALT, GGTP, alkaline phosphatase), CBC, liver synthetic function (albumin, PT, PTT), pancreatic function (amylase, lipase)
- If serum total bilirubin and direct bilirubin are elevated and urine is positive for bilirubin, consider intrahepatic or posthepatic process. If serum total bilirubin is elevated but direct bilirubin is normal (unconjugated hyperbilirubinemia) and urine is negative for bilirubin, consider prehepatic or intrahepatic processes

Additional tests if diagnosis unclear:
- Screen for hepatitis A, B, and C; if still unclear, then consider following options based on H&P
- Other viruses: EBV, CMV
- Autoimmune disorders: Antimitochondrial antibody (elevated in primary biliary cirrhosis); anti-smooth muscle antibody, ANA (elevated in autoimmune hepatitis); antinuclear cytoplasmic antibody (elevated in primary sclerosing cholangitis)
- Ceruloplasmin (elevated in Wilson disease)
- Alpha-1 antitrypsin deficiency (elevated in cirrhosis and emphysema)
- Ferritin, Fe saturation (elevated in hemochromatosis)
- Blood smear (RBC dyscrasias)
- Diagnosis of exclusion: Gilbert syndrome
- Liver biopsy: Essential in diagnosis of chronic hepatitis. Can be used for diagnosis of liver masses but carries a substantial risk

IMAGING STUDIES

- Abdominal ultrasound: First-line study (Figs. E2 and E3) may be completed bedside, most sensitive for proximal biliary tract disease; presence of dilated ducts hints at an extrahepatic process.

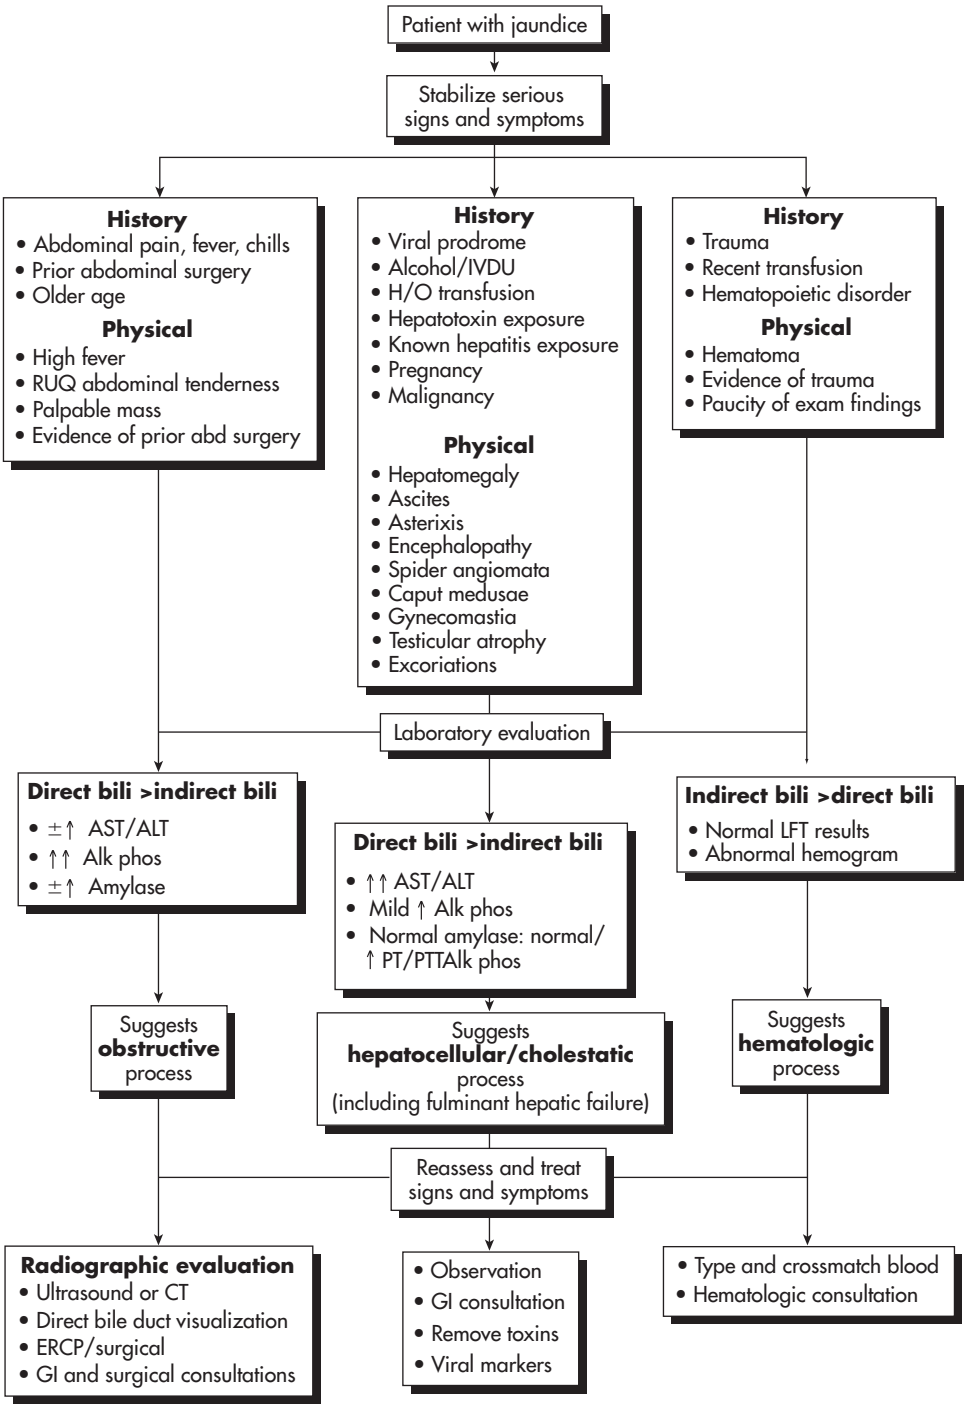

FIG. 1 Management of the patient with jaundice. *Alk phos,* Alkaline phosphatase; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase; *bili,* bilirubin; *CT,* computed tomography; *ERCP,* endoscopic retrograde cholangiopancreatography; *GI,* gastrointestinal; *H/O,* history of; *IVDU,* intravenous drug use; *LFT,* liver function test; *PT,* prothrombin time; *PTT,* partial thromboplastin time; *RUQ,* right upper quadrant. (From Marx AJ et al: *Rosen's emergency medicine: concepts and clinical practice,* ed 7, Philadelphia, 2010, Elsevier.)

- Abdominal CT: Often necessary to elucidate more information on liver, pancreas, and distal biliary system.
- Endoscopic retrograde cholangiopancreatography: Rarely necessary for diagnostics. Refer to GI consultant.
- Percutaneous transhepatic cholangiography: Rarely necessary for diagnostics. Refer to GI or surgical consultant.
- Magnetic resonance cholangiopancreatography: Noninvasive visualization of bile and pancreatic ducts. Refer to GI consultant.
- Endoscopic ultrasound: Used for characterization and, if needed, biopsy of any focal lesions found within biliary tree and/or pancreas. Refer to GI consultant.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Depends on underlying cause of the jaundice and clinical stability of the patient. Generally, obstructive causes require surgical treatment, while nonobstructive causes require medical treatment.

TABLE 1 Jaundice: Differential Diagnosis of Critical and Emergent Diagnoses

System	Critical	Emergent	Nonemergent
Hepatic	Fulminant hepatic failure	Hepatitis of any cause with confusion, bleeding, or coagulopathy	Hepatitis with normal mental status, normal vital signs, and no active bleeding
	Toxin	Wilson disease	
	Virus	Primary biliary cirrhosis	
	Alcohol	Autoimmune hepatitis	
	Ischemic insult	Liver transplant rejection	
	Reye syndrome	Infiltrative liver disease	
		Drug induced (isoniazid, phenytoin, acetaminophen, ritonavir, halothane, sulfonamides)	
		Toxin ingestion or exposure	
Biliary	Cholangitis	Bile duct obstruction (stone, inflammation, stricture, neoplasm)	
Systemic	Sepsis	Sarcoidosis	Posttraumatic hematoma resorption
	Heatstroke	Amyloidosis	Total parenteral nutrition
		Graft-versus-host disease	
Cardiovascular	Obstructing AAA	Right-sided congestive heart failure	
	Budd-Chiari syndrome	Veno-occlusive disease	
	Severe congestive heart failure		
Hematologic-oncologic	Transfusion reaction	Hemolytic anemia	Gilbert syndrome
		Massive malignant infiltration	Physiologic neonatal jaundice
		Inborn error of metabolism	
		Pancreatic head tumor	
		Metastatic disease	
Reproductive	Preeclampsia or HELLP syndrome	Hyperemesis gravidarum	
	Acute fatty liver of pregnancy		Cholestasis of pregnancy

AAA, Abdominal aortic aneurysm; *HELLP,* hemolysis, elevated liver enzymes, low platelets.
From Marx JA et al: *Rosen's emergency medicine,* ed 8, Philadelphia, 2014, Saunders.

ACUTE GENERAL Rx

Acute, life-threatening illness (e.g., cholecystitis or ascending cholangitis) requires prompt diagnosis with basic labs and bedside diagnostics, with early surgical and GI consultation in conjunction. Suspicious medications should be stopped. Initiate medical management of symptoms with analgesia, IV fluids, correction of coagulopathies, and consideration of antibiotics. *N*-Acetylcysteine can be given for acetaminophen overdose.

CHRONIC Rx

Reversible causes must be ruled out first—suspicious medications and EtOH must be discontinued. Consider GI consult for management of many intrahepatic diseases, such as treatment of hepatitis B or C, Wilson disease with penicillamine, hemochromatosis with phlebotomy, or for stent insertion with ERCP for posthepatic obstruction. Consider surgical consult for resection of pancreatic masses, cholecystectomy, etc.

Symptomatic pruritus may be treated with cholestyramine for bilirubin binding or with antihistamines to decrease the itch reflex. Ursodiol may be used to treat primary biliary cirrhosis and for gallstone prevention/dissolution.

PEARLS & CONSIDERATIONS

COMMENTS

- Heed the warning signs of unstable vital signs to diagnose life-threatening illness; early collaboration with surgical and gastroenterology colleagues is helpful in complex patient care scenarios.
- Careful history and physical examination, basic labs, and prompt bedside imaging frequently lead to accurate diagnosis.
- Very high serum bilirubin (>15 mg/dl) is most likely to be seen in cirrhosis. Watch for hepatorenal syndrome in these patients.

Junctional Rhythm

BASIC INFORMATION

DEFINITION

Junctional rhythm is an abnormal cardiac rhythm originating in the His bundle or atrioventricular (AV) node. This diagnosis includes three distinct entities based on rate:

1. A junctional escape rhythm has a rate of 40-60 bpm.
2. Accelerated junctional rhythm has a rate of 60-100 bpm.
3. Junctional ectopic tachycardia (JET) has a rate of >100 bpm.

SYNONYMS

Junctional escape rhythm
Accelerated junctional rhythm
Junctional ectopic tachycardia (JET)
Nodal rhythm disorder
Ectopic rhythm disorder
Junctional premature depolarization

ICD-10CM CODE
I49.2 Junctional premature depolarization

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Junctional rhythm occurs more commonly in children due to higher vagal tone (13% of 10- to 13-yr-old boys, 45% of 7- to 10-yr-old children, and 19% of infants have junctional rhythm during sleep).[1] Endurance athletes have a 20% incidence of junctional rhythm, for a similar reason.

PREVALENCE: Junctional tachycardia is a rare cause of supraventricular tachycardia. It is rare in the pediatric population and even less common in adults. On the contrary, junctional rhythm is common although the prevalence is not well defined.

GENETICS: There is no known hereditary component.

RISK FACTORS: Conduction system disease, heart block, digitalis intoxication, heart surgery, endocarditis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

ESSENTIAL HISTORY:

- Previous history of syncope, presyncope, lightheadedness.
- Drugs, especially digoxin. Amount taken, time of ingestion. The digestion time is especially important because the serum digoxin level ideally should be measured at least 6 hours after ingestion to ensure accuracy. Obtain a thorough medication history to determine if any recent additions or dosing changes were made.

SYMPTOMS:

- Lightheadedness
- Syncope
- Palpitations
- Symptoms associated with digitalis intoxication: Gastrointestinal symptoms such as anorexia, nausea, vomiting, and abdominal pain. Neurologic manifestation such as lethargy, fatigue, delirium, confusion, weakness. Visual changes: Alteration in color vision, diplopia, photophobia, decreased visual acuity

PHYSICAL EXAMINATION:

- Vital signs
- Look for evidence of hypoperfusion and end organ dysfunction
- Cannon A-waves on examination of the jugular pulse

ETIOLOGY

Junctional tachycardia can occur as a primary arrhythmia (usually in children-JET), secondary to digitalis intoxication or catecholamine intoxication, or in the setting of injury to the His bundle (e.g., after valve surgery, abscess, sarcoidosis, myocarditis, ischemia, etc.).

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- AVNRT (atrioventricular nodal reentrant tachycardia)
- AVRT (atrioventricular reentrant tachycardia)
- Accelerated idioventricular rhythm–in the case of junctional rhythm with aberrant conduction
- Fig. 1 illustrates arrhythmias originating in the atrioventricular node

WORKUP

- Vital signs
- 12-lead ECG (Figs. 2 and 3). The rhythm is almost perfectly regular and the QRS complex is generally narrow and similar to the complex seen during sinus rhythm. Retrograde P waves with a very short interval from QRS to P wave can be seen
- History of cardiac surgery, fevers, drug ingestion

LABORATORY TESTS

- Serum digoxin concentration
- Serum potassium concentration
- Creatinine and blood urea nitrogen (BUN) to assess renal function
- Troponin

IMAGING STUDIES

Echocardiogram

TREATMENT

Junctional tachycardia may be a marker for a serious underlying condition such as digitalis toxicity, postcardiac surgery, endocarditis, hypokalemia, or myocardial ischemia. Underlying conditions should be sought and corrected accordingly.

NONPHARMACOLOGIC THERAPY

- Junctional escape rhythm in the setting of sinus arrest or complete heart block without reversible cause necessitates permanent pacemaker implantation.
- Junctional ectopic tachycardia can be treated with antiarrhythmics or radiofrequency ablation.

ELECTROPHYSIOLOGY STUDY: The origin of this tachycardia is within the His bundle or AV node, and it can be diagnosed definitively by intracardiac recordings. Junctional rhythm most frequently takes the form of escape rhythms in the presence of sinus node dysfunction or AV nodal block, which can be diagnosed on electrophysiology (EP) study. These escape rhythms usually have a QRS morphology identical to that seen during sinus rhythm. In such cases, there is no P wave before the QRS complexes. The P waves can occur simultaneously with the QRS complexes; more commonly, they are retrograde. When the junctional rhythm is faster than 100 beats/min, it is called junctional tachycardia.

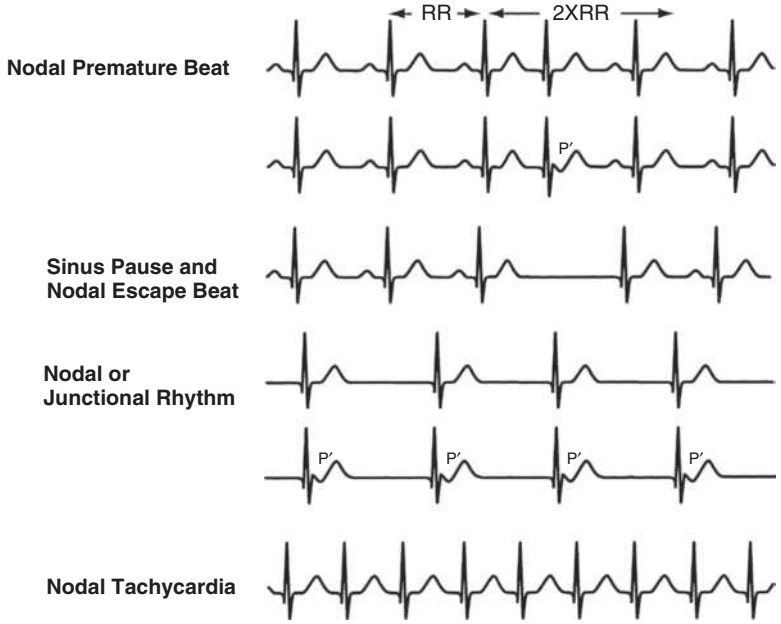

FIG. 1 Arrhythmias originating in the atrioventricular node. (From Park MK: *Park's pediatric cardiology for practitioners,* ed 6, Philadelphia, 2014, Elsevier.)

[1]Drago F et al: Neonatal and pediatric arrhythmias: clinical and electrocardiographic aspects, *Card Electrophysiol Clin* 10(2):397-412, 2018.

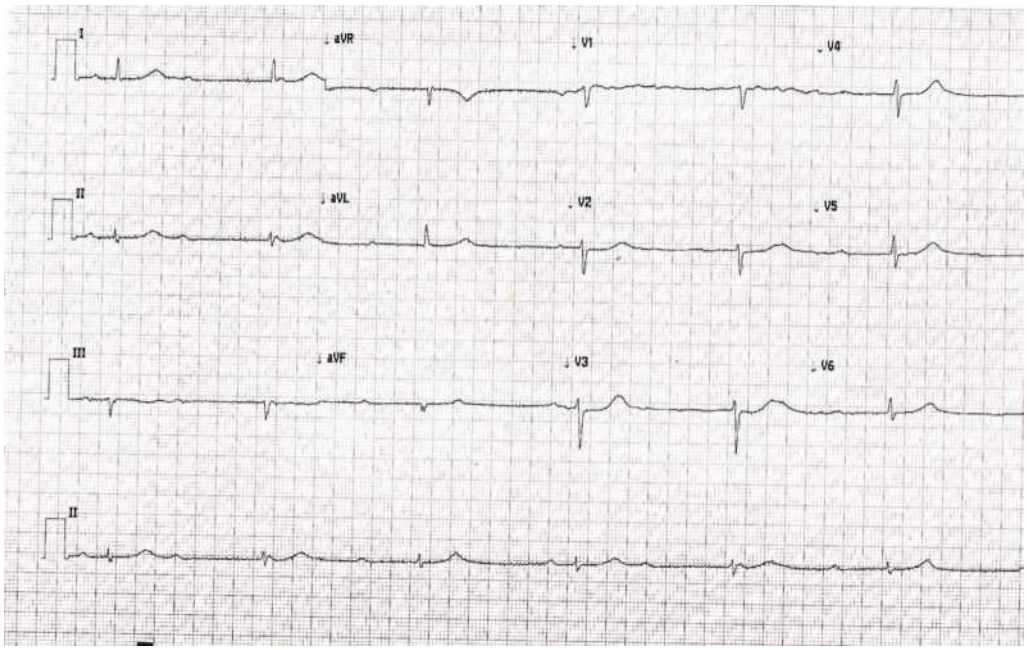

FIG. 2 Electrocardiogram of a patient with junctional rhythm and complete heart block. Note the narrow QRS complex and dissociated P waves. *aVF,* Augmented vector foot; *aVL,* augmented vector left; *aVR,* augmented vector right.

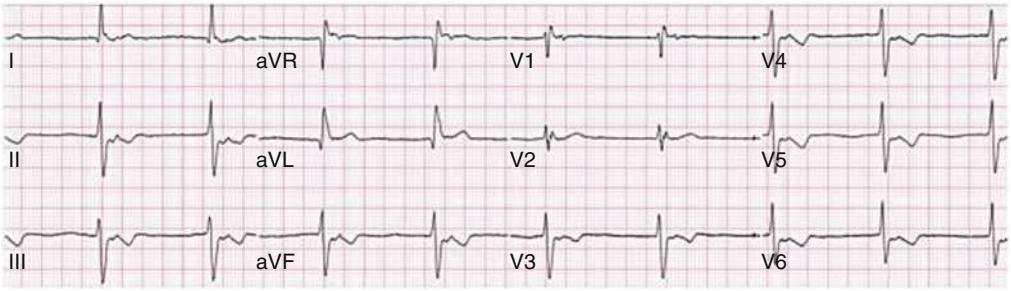

FIG. 3 Junctional rhythm with retrograde P waves that are negative in the inferior leads. *aVF,* Augmented vector foot; *aVL,* augmented vector left; *aVR,* augmented vector right. (From Parrillo JE, Dellinger RP: *Critical care medicine: principles of diagnosis and management in the adult,* ed 4, Philadelphia, 2014, Elsevier.)

ACUTE GENERAL Rx

The mainstay of managing nonparoxysmal junctional tachycardia is to correct the underlying abnormality. Withholding digitalis when junctional tachycardia is the only clinical manifestation of toxicity is usually adequate. If, however, ventricular arrhythmias or high-grade heart block are observed, then treatment with digitalis-binding agents may be indicated.

COMPLEMENTARY & ALTERNATIVE MEDICINE

N/A

DISPOSITION

Admit to cardiac telemetry if symptomatic. Consider specialty referral to cardiac electrophysiology.

REFERRAL

Refer to cardiologist.

PEARLS & CONSIDERATIONS

COMMENTS

- Junctional rhythm often is observed in patients with AV dissociation, which can lead to atrial contraction against closed atrioventricular valves, resulting in cannon A waves. This wave will cause pulsation in the neck and abdomen, headache, cough, jaw pain and possible hypotension.
- The presence of a perfectly regular rhythm in a patient with atrial fibrillation often indicates junctional rhythm with complete heart block.

PREVENTION

N/A

Juvenile Idiopathic Arthritis ALG PTG

BASIC INFORMATION

DEFINITION

Juvenile idiopathic arthritis (JIA), previously referred to as juvenile rheumatoid arthritis (JRA), is a diverse spectrum of chronic arthritides, involving ≥1 joints for ≥6 wk in a patient ≤16 yr of age. Other causes of arthritis must be excluded.

SYNONYMS

JIA
JRA
Juvenile rheumatoid arthritis (JRA)
Still disease (specifically systemic JIA)

ICD-10CM CODES

M08.00	Unspecified juvenile rheumatoid arthritis of unspecified site
M08.09	Unspecified juvenile rheumatoid arthritis, multiple sites
M08.20	Juvenile rheumatoid arthritis with systemic onset, unspecified site
M08.29	Juvenile rheumatoid arthritis with systemic onset, multiple sites
M08.40	Pauciarticular juvenile rheumatoid arthritis, unspecified site

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: 1 per 1000 children in the U.S.; more common in children of European ancestry

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- JIA is subdivided into seven categories based on the International League of Associations for Rheumatology (ILAR) classification criteria (summarized in Table 1). Characteristics of the various categories of JIA are summarized in Table 2.
  1. Systemic onset JIA (sJIA) (4% to 17%)
     a. Arthritis in ≥1 joints with or preceded by fever (Fig. E1) of at least 2-wk duration that is quotidian (once daily) for at least 3 days and associated with at least one of the following: (1) evanescent erythematous rash (Fig. E2); (2) generalized lymphadenopathy; (3) hepatomegaly, splenomegaly, or both; and (4) serositis.
- Oligoarticular JIA (Fig. E3) (27% to 56%)
  1. Arthritis in <4 joints in the first 6 mo of disease. There are two subtypes:
     a. Persistent: ≤4 joints throughout the disease course.
     b. Extended: ≤4 joints during the first 6 mo extending to >4 joints after 6 mo.
- Polyarthritis, rheumatoid factor (RF) negative (11% to 28%)
  1. Arthritis in >5 joints during first 6 mo of the disease with negative RF.
- Polyarthritis, RF positive (2% to 7%)
  1. Arthritis involves ≥5 joints during first 6 mo of the disease with positive RF on >2 tests run 3 mo apart.
  2. Anticyclic citrullinated (CCP) antibodies may also be present.
  3. Most similar to adult rheumatoid arthritis; most likely to progress.
- Psoriatic arthritis (2% to 11%)
  1. Psoriasis and arthritis or psoriasis and ≥2 of the following:
     a. Dactylitis, nail pitting, onycholysis, and psoriasis in a first-degree relative.
- Enthesitis-related arthritis (3% to 11%)
  1. Arthritis or enthesitis and ≥2 of the following:
     a. Sacroiliac tenderness, positive HLA-B27, male age >6 yr, acute anterior uveitis, or first-degree relative with HLA-B27-associated disease.
- Undifferentiated arthritis (11% to 21%)
  1. Fulfills criteria in ≥2 categories above, or none of them

ETIOLOGY

Genetically susceptible individuals may develop an inappropriate immune response toward a self-antigen after exposure to an environmental trigger. Variants in HLA, PTPN22, and STAT4 loci may be associated with disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infection: Viral (parvovirus, toxic synovitis) or bacterial (Lyme, osteomyelitis, septic joints)
- Inflammation: Lupus, serum sickness, inflammatory bowel disease
- Reactive: Poststreptococcal, rheumatic fever
- Malignancy: Leukemia, bone tumors
- Table 3 summarizes conditions with arthralgia or arthritis that might be confused with JIA

TABLE 1 Overview of the Main Features of the Subtypes of Juvenile Idiopathic Arthritis

ILAR Subtype	Peak Age of Onset (yr)	Female:Male; % of All JIA	Arthritis Pattern	Extraarticular Features	Investigations	Notes on Therapy
Systemic arthritis	2-4	1:1; ~10% of JIA cases	Polyarticular, often knees, wrists, and ankles; also fingers, neck, and hips	Daily fever; evanescent rash; pericarditis; pleuritis	Anemia; WBC↑↑; ESR↑↑; CRP↑↑; ferritin;↑ platelets↑↑ (normal or ↑ in MAS)	Less responsive to standard treatment with MTX and anti-TNF agents; consider IL-1Ra in resistant cases
Oligoarthritis	>6	4:1; 50%-60% of JIA (but ethnic variation)	Knees ++; ankles, fingers +	Uveitis in ~30%	ANA positive in 60%; other tests usually normal; may have mildly ↑ ESR/CRP	NSAIDs and intraarticular steroids; occasionally require MTX
Polyarthritis, RF negative	6-7	3:1; 30% of JIA cases	Symmetric or asymmetric; small and large joints; cervical spine; TMJ	Uveitis in ~10%	ANA positive in 40%; RF negative; ESR ↑ or; ↑↑ CRP↑/normal; mild anemia	Standard therapy with MTX and NSAIDs, then if nonresponsive, anti-TNF agents or other biologics
Polyarthritis, RF positive	9-12	9:1; >10% of JIA cases	Aggressive symmetric polyarthritis	Rheumatoid nodules in 10%; low-grade fever	RF positive; ESR ↑↑; CRP ↑/normal; mild anemia	Long-term remission unlikely; early aggressive therapy is warranted
Psoriatic arthritis	7-10	2:1; >10% of JIA cases	Asymmetric arthritis of small or medium sized joints	Uveitis in 10%; psoriasis in 50%	ANA positive in 50%; ESR ↑; CRP ↑/normal; mild anemia	NSAIDs and intraarticular steroids; second-line agents less commonly
Enthesitis-related arthritis	9-12	1:7; 10% of JIA cases	Predominantly lower limb joints affected; sometimes axial skeleton (but less than adult AS)	Acute anterior uveitis; association with reactive arthritis and IBD	80% HLA-B27	NSAIDs and intraarticular steroids; consider sulfasalazine as alternative to MTX

ANA, Antinuclear antibody; *AS,* ankylosing spondylitis; *CRP,* C-reactive protein; *ESR,* erythrocyte sedimentation rate; *IBD,* inflammatory bowel disease; *ILAR,* International League of Associations for Rheumatology; *IL-1Ra,* interleukin-1 receptor antagonist; *JIA,* juvenile idiopathic arthritis; *MAS,* macrophage activation syndrome; *MTX,* methotrexate; *NSAID,* nonsteroidal antiinflammatory drug; *RF,* rheumatoid factor; *TMJ,* temporomandibular joint; *TNF,* tumor necrosis factor; *WBC,* white blood cell count.

TABLE 2 Characteristics of the Various Categories of Juvenile Idiopathic Arthritis

Category	Age at Onset	Affected Joints	Systemic Features	Major Complications
Oligoarticular persistent	Early childhood	Large joints, asymmetric (knee, ankle, wrist, elbow, temporomandibular, cervical spine)	No	Chronic uveitis Local growth disturbances
Oligoarticular extended	Early childhood	Same as above, but more than four joints involved after the first 6 mo of disease	No	Chronic uveitis Local growth disturbances
Polyarticular RF negative	Throughout childhood	Any, often symmetric, often small joints	Malaise (subfebrile)	Chronic uveitis Local growth disturbances
Polyarticular RF positive	Teenage years	Any, usually symmetric and involving small joints	Malaise (subfebrile)	Local growth disturbances and articular damage
Systemic	Throughout childhood	Any (not necessarily at disease onset)	High fever, rash, polyserositis, marked acute-phase response	Acute: Macrophage activation syndrome Chronic: General growth disturbance, amyloidosis
Psoriatic	Late childhood	Spine, lower extremities, distal interphalangeal joints, dactylitis		Psoriasis Local growth disturbances
Enthesitis related	Late childhood	Spine, sacroiliac, lower extremities, thoracic cage joints	Inflammatory bowel disease	Acute symptomatic uveitis

RF, Rheumatoid factor.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

TABLE 3 Conditions with Arthralgia or Arthritis that Might Be Confused with Juvenile Idiopathic Arthritis

Type of Condition	Examples
Infections	Bacterial arthritis and osteomyelitis
	Borreliosis (Lyme disease)
	Viral and mycoplasmal arthritis
	Tuberculosis
Postinfectious conditions	Rheumatic fever
	Poststreptococcal arthritis
	Postenteritis and other reactive arthritis *(Salmonella, Campylobacter, Chlamydia)*
Noninflammatory conditions	Hypermobility and Ehlers-Danlos syndrome
	Growing pains, trauma, patellofemoral and other overuse syndromes
	Osgood-Schlatter disease and other juvenile osteochondroses
	Legg-Calvé-Perthes disease
	Slipped capital femoral epiphysis
	Foreign body synovitis
	Other congenital and genetic disorders of supportive tissue
Hematologic disorders	Sickle cell anemia
	Hemophilia
	von Willebrand disease
Systemic inflammatory disorders	Juvenile systemic lupus erythematosus
	Juvenile dermatomyositis
	Mixed connective tissue disease
	Scleroderma
	Vasculitis (e.g., Henoch-Schönlein purpura, Kawasaki disease, Behçet disease)
Autoinflammatory disorders	Cryopyrin-associated periodic syndrome
	Familial Mediterranean fever
	Other monogenic diseases (e.g., mevalonate kinase deficiency [hyperimmunoglobulinemia D], Blau syndrome, tumor necrosis factor receptor–associated periodic syndrome)
	Chronic recurrent multifocal osteomyelitis
	Periodic fever, aphthous stomatitis, pharyngitis, and adenitis (PFAPA syndrome)
Malignancies	Leukemia
	Neuroblastoma
	Localized bone tumors
Pain	Complex regional pain syndrome
	Pain amplification syndromes and fibromyalgia
	Nonspecific musculoskeletal pain
Miscellaneous conditions	Primary immunodeficiencies
	Sarcoidosis

From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

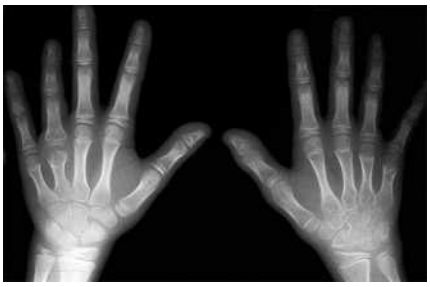

FIG. 4 Juvenile idiopathic arthritis (JIA). Oligoarticular-onset JIA in an 8-year-old. Epiphyseal destruction and undergrowth of the third metacarpophalangeal joint of the left hand are seen, as well as overgrowth of the carpal bones of the right wrist compared with the left wrist. Also note the widened appearance of the third phalanges caused by periosteal new bone formation. (From Hochberg MC et al: *Rheumatology,* ed 5, St Louis, 2011, Mosby.)

FIG. 5 Severe hip disease in a 13-year-old boy with active, systemic-onset juvenile idiopathic arthritis. Radiograph shows destruction of the femoral head and acetabula, joint space narrowing, and subluxation of left hip. The patient had received corticosteroids systemically for 9 years. (From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, WB Saunders.)

LABORATORY TESTS

- No single diagnostic test. Must rule out other causes of arthritis
- Elevated sedimentation rate and C-reactive protein; high ferritin
- Mild anemia, leukocytosis (WBC can be very high)
- Rheumatoid factor
- Antinuclear antibodies: Elevation associated with ocular complications
- Pancytopenia, a consumptive coagulopathy, elevated ferritin, and elevated liver enzymes are concerning for macrophage activation syndrome (MAS) in sJIA

IMAGING STUDIES

- Radiographs show soft tissue swelling and periarticular osteopenia early in the disease (Fig. 4).
- Joint destruction (Fig. 5) is less frequent, but bony erosion and cyst formation may be present.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Collaboration among the patient's pediatrician, rheumatologist, orthopedist, and physical therapist, along with education regarding weight management, is essential.

CHRONIC GENERAL RX

- NSAIDs: Used as monotherapy or in conjunction with intraarticular steroids
- DMARDs: Methotrexate, leflunomide, sulfasalazine
  1. Required by two thirds of children
  2. Axial involvement is less responsive to methotrexate
- Biologics: Improve morbidity associated with JIA. Individual subtypes show different responses to therapy.
  1. Tumor necrosis factor antagonists such as etanercept and adalimumab
  2. T-cell modulator, abatacept
  3. IL-1 (anakinra) and IL-6 antagonists (tocilizumab) useful in sJIA

Meta-analysis of randomized controlled trials did not show statistically significant differences in the efficacy or safety profile of these agents.

- Systemic corticosteroids should be limited when possible.
- Major medications and indications for treatment of JIA are summarized in Table 4. Fig. 6 illustrates an algorithm for medical treatment of oligoarticular-onset JIA. Treatment of polyarticular-onset JIA is illustrated in Fig. 7, and treatment of systemic onset JIA in Fig. 8.

DISPOSITION

- More than 50% continue to have active disease into adulthood.
- Patients with persistent oligoarticular disease are most likely to achieve remission, while those who are RF positive are least likely to achieve remission.
- Macrophage activation syndrome is a life-threatening complication of sJIA.
- Asymmetric joint involvement can lead to growth failure and limb length discrepancies.

REFERRAL

- Early rheumatology consultation
- Ophthalmology consultation at diagnosis and at least annually
- Children <7 yr old, with + ANA are at the highest risk for ocular inflammation (uveitis) and require screening every 3 to 4 mo

PEARLS & CONSIDERATIONS

COMMENTS

JIA is an autoinflammatory disease with a strong genetic component. Genomics is increasingly used to identify susceptibility loci. Immunomodulators have improved therapy in refractory disease. Normalization of the immune response early in the disease can limit disease progression. Children with JIA have an increased rate of malignancy compared with the general population.

TABLE 4 Major Medications and Indications for Treatment of Juvenile Idiopathic Arthritis

Medication	Arthritis Subtype	Indication
NSAIDs	All types	Symptomatic: pain, stiffness, serositis, antiinflammatory in mild cases
Intraarticular corticosteroids	All types, mainly oligoarthritis	Injection of few active joints
Systemic corticosteroids	Systemic, polyarthritis	Fever, serositis, bridging medication, MAS
Methotrexate	All types; less effective for systemic and enthesitis-related axial disease	Disease modifying
Leflunomide	Polyarthritis	Disease modifying
Sulfasalazine	Oligoarthritis, polyarthritis, enthesitis-related peripheral disease	Disease modifying
Cyclosporine	Systemic	MAS
Thalidomide	Systemic	Biologic modifier
Anti-TNF (etanercept infliximab, adalimumab, golimumab, certolizumab)	Polyarthritis, enthesitis-related, uveitis (infliximab, adalimumab), less effective for systemic disease	Biologic modifier
Abatacept	Polyarthritis	Biologic modifier
Anti–IL-1 (anakinra, canakinumab, rilonacept)	Systemic	Biologic modifier, MAS
Anti–IL-6 (tocilizumab)	Systemic, polyarthritis	Biologic modifier
IVIG	Systemic	Steroid sparing, MAS

IL-1, interleukin-1; *IVIG,* intravenous immune globulin; *MAS,* macrophage activation syndrome; *NSAID,* nonsteroidal antiinflammatory drug; *TNF,* tumor necrosis factor.
From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.

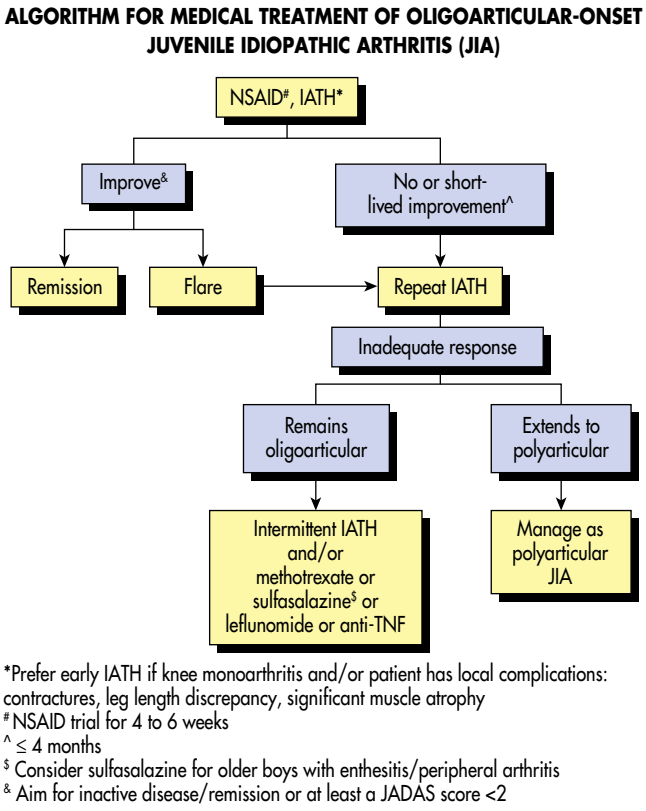

FIG. 6 Medical treatment of the oligoarticular type of juvenile idiopathic arthritis (JIA). *IATH,* Intraarticular triamcinolone hexacetonide; *JADAS,* Juvenile Arthritis Disease Activity Score; *NSAID,* nonsteroidal antiinflammatory drug; *TNF,* tumor necrosis factor. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

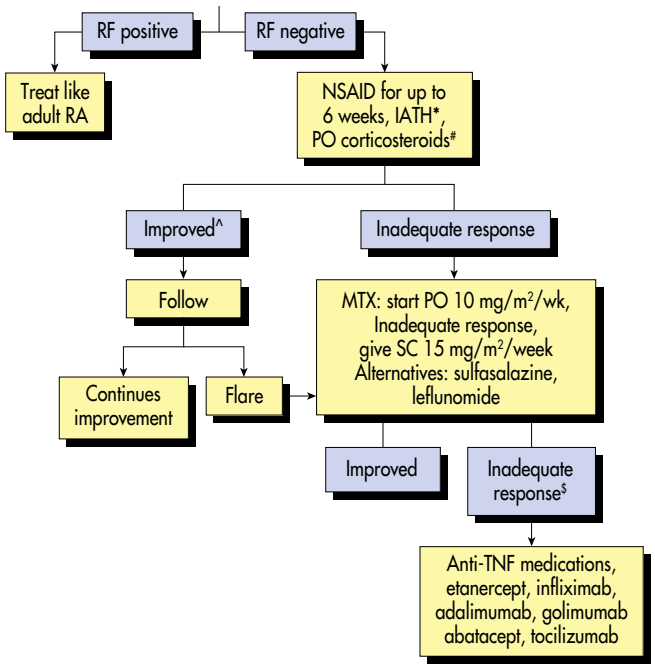
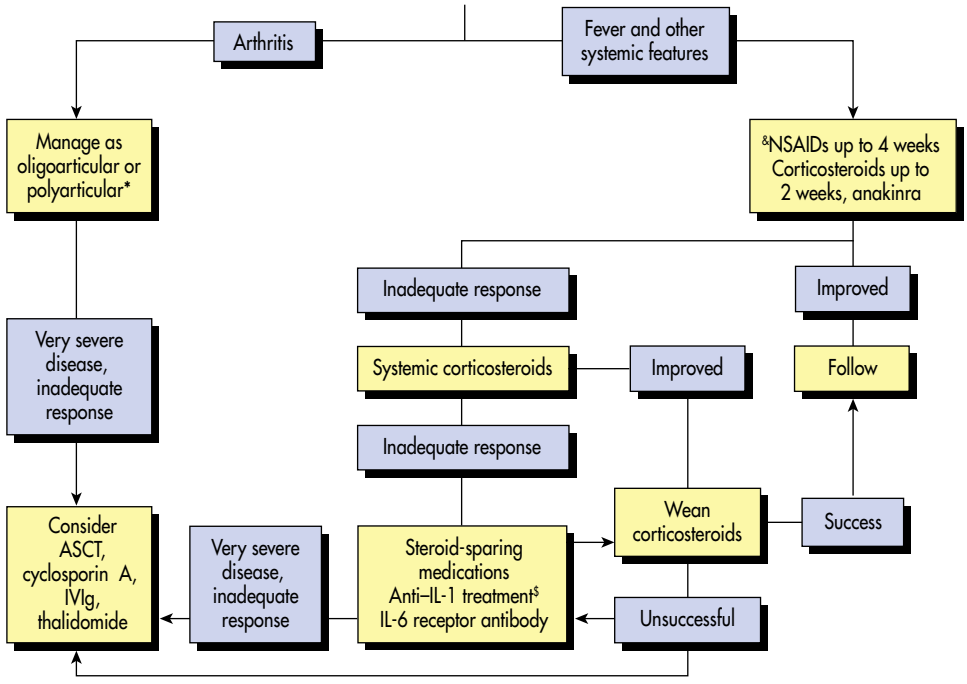
ALGORITHM FOR MEDICAL TREATMENT OF POLYARTICULAR-ONSET JUVENILE IDIOPATHIC ARTHRITIS (JIA)



* IATH for selected joints
# PO steroids can be considered as bridging medicine or during significant flares
$ If fails to respond to one anti-TNF agent, consider changing to another or to abatacept
^ Improved: pediatric ACR 70 response (or JADAS score <3.8)

FIG. 7 Medical treatment of the polyarticular type of juvenile idiopathic arthritis (JIA). *ACR70,* American College of Rheumatology 70% improvement; *IATH,* intraarticular triamcinolone hexacetonide; *JADAS,* Juvenile Arthritis Disease Activity Score; *MTX,* methotrexate; *NSAID,* nonsteroidal antiinflammatory drug; *PO,* oral; *SC,* subcutaneous; *RA,* rheumatoid arthritis; *RF,* rheumatoid factor; *TNF,* tumor necrosis factor. (From Hochberg MC: *Rheumatology,* ed 7, Philadelphia, 2019, Elsevier.)

ALGORITHM FOR MEDICAL TREATMENT OF SYSTEMIC-ONSET JUVENILE IDIOPATHIC ARTHRITIS (JIA)



* Methotrexate, intraarticular corticosteroids, anti-tumor necrosis factor drugs are less effective in systemic-onset JIA; anti-IL-1 and IL-6 receptor antibody may be more effective
$ Anti IL-1 treatments include anakinra, rilonacept, canakinumab
& Depends on physician global assessment and number of active joints

FIG. 8 Medical treatment of systemic juvenile idiopathic arthritis (JIA). *ASCT,* Autologous stem cell transplantation; *IL,* interleukin; *IVIG,* intravenous immunoglobulin; *NSAID,* nonsteroidal antiinflammatory drug; *TNF,* tumor necrosis factor. BASIC INFORMATION

DEFINITION

Kaposi sarcoma (KS) is a low-grade vascular tumor associated with Kaposi sarcoma herpes virus (KSHV) infection and is an AIDS-defining illness. Kaposi sarcoma lesions present predominantly at mucocutaneous sites but may involve all organs and anatomic locations.

SYNONYM

KS

ICD-10CM CODES

C46.0	Kaposi sarcoma of skin
C46.1	Kaposi sarcoma of soft tissue
C46.2	Kaposi sarcoma of palate
C46.3	Kaposi sarcoma of lymph nodes
C46.4	Kaposi sarcoma of gastrointestinal sites
C46.50	Kaposi sarcoma of unspecified lung
C46.51	Kaposi sarcoma of right lung
C46.52	Kaposi sarcoma of left lung
C46.7	Kaposi sarcoma of other sites
C46.9	Kaposi sarcoma, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- AIDS-related KS affects >35% of AIDS cases.
- Highest incidence is in homosexual men.

ETIOLOGY & CLASSIFICATION

KSHV has been isolated from patients with most forms of KS and is thought to be the causative agent. It can be transmitted sexually (homosexual or heterosexual activities) and by other forms of nonsexual contact such as maternal-infant transmission (common in African countries). KSHV establishes lifelong infection in the host, and its DNA is found in all KS lesions. KS prevalence follows KSHV seroprevalence, and in most cases fulminant KS is accompanied and preceded by a rise in KSHV viral load in the blood. KS is primarily the consequence of systemic viral reactivation from a latent reservoir, most likely a lymph node resident B cell. It appears that KS develops in response to severe T-cell depletion or inactivation. Infant immunodeficiency or aging-, chemical-, or HIV-induced immune deficiency is an essential cofactor for the development of KS.

It can be divided into the following four subsets:

1. Classic KS: Occurs mostly in elderly Eastern European and Mediterranean males. It consists initially of violaceous macules and papules with subsequent development of plaques and red-purple nodules. Growth is slow, and most patients die of unrelated causes.
2. Epidemic (AIDS-related) KS: Most frequently occurs in homosexual men. Lesions are generally multifocal and widespread (Fig. E1). Lymphadenopathy may be associated.
3. Endemic KS: Usually affects sub-Saharan African children and adults. An aggressive lymphadenopathic form affects African children in particular.
4. Immunosuppression-associated, or transplantation-associated, KS: Usually associated with immunosuppressive therapy.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- KS lesions evolve from early (patch stage) macules into plaques (plaque stage) that may subsequently develop into larger nodules (tumor stage). These tumors may ulcerate, cause marked lymphedema, present as exophytic growths (e.g., cutaneous horns), or invade subjacent tissues (e.g., underlying bone). Different stages can coexist in the same individual at the same time.
- Although KS commonly presents at mucocutaneous sites, tumors may involve lymph nodes as well as visceral organs, most notably the respiratory and gastrointestinal tracts.
- Extracutaneous KS has also been described in unusual anatomic locations, including the musculoskeletal system, nervous system, heart, wounds, within pemphigus lesions, and in blood clots.
- AIDS-related KS: Multifocal and widespread red-purple (Fig. E1) or dark plaques and/or nodules on cutaneous or mucosal surfaces. This is a more aggressive illness with early dissemination.
- Generalized lymphadenopathy at the time of diagnosis is present in >50% of patients with AIDS-related KS; the initial lesions have a rust-colored appearance; subsequent progression to red or purple nodules or plaques occurs (Fig. E2).
- Most frequently affected areas are the face, trunk, oral cavity, and upper and lower extremities.
- The GI tract is the most frequent site of internal involvement in classic KS.
- In AIDS-associated KS, 25% of patients have cutaneous involvement alone, whereas 29% have visceral lesions only (lymph nodes 50%, GI tract 50%, lungs 37%).
- In most patients with HIV-associated KS who initiate HAART, the KS lesions stabilize with decreasing HIV plasma viremia and immune reconstitution, or even resolve completely without any specific treatment.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Stasis dermatitis
- Pyogenic granuloma
- Capillary hemangiomas
- Granulation tissue
- Postinflammatory hyperpigmentation
- Cutaneous lymphoma
- Melanoma
- Dermatofibroma
- Hematoma
- Prurigo nodularis

WORKUP

Diagnosis can generally be made on clinical appearance in a patient with one of the earlier clinical categories; a tissue biopsy is required to confirm the diagnosis.

LABORATORY TESTS

HIV in patients suspected of AIDS

TREATMENT

NONPHARMACOLOGIC THERAPY

Observation is a reasonable option in patients with slowly progressive disease. At present, there is no cure for KS.

GENERAL Rx

- Treatment goals of KS include symptom palliation, prevention of progression and organ compromise, improvement of cosmesis, and relieving psychologic stress. An algorithm for management of AIDS-associated Kaposi sarcoma is illustrated in Fig. E3.
- A significant proportion of HIV-related KS cases can regress following the start of ART alone, indicating the role of immune reconstitution in the management of this disease.
- All types of KS are radiosensitive. Radiation therapy is effective in non-AIDS KS and for large tumor masses that interfere with normal function.
- Surgical excision is restricted for cosmetically disturbing KS lesions, to alleviate discomfort, or to control local tumor growth. It often provides adequate treatment for single lesions and resected recurrences in classic KS.
- Liquid nitrogen cryotherapy can result in complete response in 80% of lesions.
- Interlesional chemotherapy with vinblastine is useful for nodular lesions >1 cm in diameter. Intralesional injection of interferon alfa-2b has also been reported as effective and well tolerated.
- Other local therapies used include laser therapy, cryotherapy, photodynamic therapy, and topical alitretinoin gel.
- Indications for systemic chemotherapy include widespread skin involvement, extensive oral KS, rapidly progressive disease, symptomatic visceral disease, and disease flare.
- Liposomal anthracyclines and paclitaxel are FDA-approved as first-line and second-line monotherapy for advanced KS. Interferon-α has been used with responses dependent upon the underlying immune status of the patient; the best responses are seen in patients with CD4 counts >400/μL.

- Current trials have shown encouraging initial responses in patients with relapsed KS with the use of thalidomide and immune checkpoint inhibitor therapy.
- Sirolimus is effective in inhibiting the progression of dermal KS in kidney transplant recipients.

PEARLS & CONSIDERATIONS

COMMENTS

- Immunosuppression-associated KS usually regresses with the cessation, reduction, or modification of immunosuppression therapy in most patients. Similarly, in HIV patients KS responds concurrently with the decrease in serum HIV RNA and increase in the CD4 count.
- Kaposi sarcoma is associated with an increased risk of developing secondary malignancies (lymphomas, leukemia, myeloma).

BASIC INFORMATION

DEFINITION

Kawasaki disease (KD) is an acute, febrile illness of unknown etiology that predominantly affects children younger than 5 yr old. It is the most common cause of acquired heart disease in children in developed countries. The pathology demonstrates a vasculitis of small- and medium-size blood vessels, with a predilection for the coronary arteries, which can result in coronary artery aneurysms. It is usually a self-limiting condition lasting an average of 12 days if not treated. Box E1 summarizes diagnostic criteria for classic or typical Kawasaki disease.

SYNONYMS

Kawasaki syndrome
Mucocutaneous lymph node syndrome
Infantile polyarteritis
KD

ICD-10CM CODE

M30.3 Mucocutaneous lymph node syndrome [Kawasaki]

EPIDEMIOLOGY & DEMOGRAPHICS

- KD is the leading cause of acquired heart disease in children in developed countries, including the U.S. and Japan. Rheumatic disease is still more common in underdeveloped countries.
- Commonly occurs in children <5 yr (80%); peak incidence is in infants ages 6 to 11 mo. Although occurrence is rare after late childhood, the disease can occur in adolescence.
- The highest incidence is found in Japan (~265 cases/100,000 children younger than 5).

BOX E1 Diagnostic Criteria for Classic or Typical Kawasaki Disease

- Fever for at least 5 days *plus* four of the following features:
  1. Bilateral conjunctival injection
  2. Polymorphous exanthem
  3. Changes in the lips and oral cavity (erythema, cracking of lips, oropharyngeal erythema, strawberry tongue)
  4. Peripheral extremity changes (erythema and swelling of hands and feet; later periungual desquamation, Beau lines)
  5. Cervical lymphadenopathy (≥1.5 cm in diameter)
- Exclusion of other diseases with similar features

The finding of fever plus three criteria in the presence of coronary abnormalities qualifies. In the presence of classic features, experienced clinicians may be able to establish a diagnosis before the fifth day of illness.

(From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.)

- Incidence of KD in the U.S. is estimated to be 25 cases/100,000 children <5 yr of age
- Children of Asian or Pacific Islander descent have a higher incidence of KD compared with those of European or African descent.
- More prevalent in males than females (1.5:1).
- Temporal clustering with winter and early spring predominance has been observed in KD in North America.
- 1% of patients with KD in Japan have a positive family history of KD.
- In Japan, the relative risk of KD in a sibling is 10-fold higher; half of these cases occur within 10 days of the initial case.
- Single-nucleotide polymorphisms in six genes or gene regions have been implicated in susceptibility to KD.
- Variants in transforming growth factor (TGF-β) signaling pathway genes have been associated with aneurysm risk in Europeans.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- The clinical presentation is characterized by a systemic inflammation of small- and medium-sized blood vessels.
- There is no specific test that is diagnostic for KD. Confirmation of the diagnosis is based on clinical criteria.
- To meet the case definition of classic or typical KD, a child will have had fever persisting for ≥5 days and the presence of ≥4 of the following five principal features, which need not be present at the same time. The diagnosis may be made with only 4 days of fever in the presence of all 5 principal clinical criteria.
  1. Bilateral, bulbar conjunctival injection with limbic sparing and without exudate.
  2. Oral mucosal changes (Fig. E1): Erythema and fissured/cracking lips, strawberry tongue, diffuse injection of the oropharyngeal mucosa.
  3. Polymorphous exanthem (Fig. E2).
  4. Extremity changes: (a) Acute: Erythema and edema of hands and feet; (b) convalescent: Membranous desquamation of fingertips.
  5. Cervical lymph node enlargement (at least one lymph node ≥1.5 cm in diameter).
- Patients with unexplained fever ≥5 days and 4 criteria are categorized as "incomplete" or "atypical KD," but with evidence of coronary artery aneurysms these individuals are classified as complete KD. These patients are more likely to be infants and older children and consequently are at higher risk for coronary aneurysms.
- The fever of KD is mildly responsive to antipyretics and is usually >102.2 °F (39 °C) and often >104.0 °F (40 °C). If untreated, it lasts for an average of 12 days.
- The rash of KD can be maculopapular, diffuse erythroderma, or erythema multiforme-like; however, vesicles, bullae, purpura, and petechiae are never observed.
- The pericardium, myocardium, endocardium, valves, and coronary arteries may be inflamed during acute illness. Cardiac abnormalities in Kawasaki disease are summarized in Box E2.
- Valvular dysfunction occurs in about 25% of patients regardless of coronary artery involvement and most often involves the mitral valve.
- Approximately 5% of children with KD in the U.S. have cardiovascular collapse and shock at clinical presentation. Often, a diagnosis of bacterial sepsis is suspected at the outset, frequently with negative cultures and persistent fevers, in which case the diagnosis of KD should be suspected.
- Coronary artery aneurysms can develop in as many as 25% of untreated children between 1 to 4 weeks of illness. This subset of patients can develop myocardial infarction (MI) and congestive heart failure over time, which may lead to death.
- New aneurysms seldom form after 6 weeks. Half of the aneurysms show angiographic regression in 1 to 2 yr.
- Coronary z-scores are the preferred method for describing internal diameter of the coronary artery normalized by body surface area and should be used to describe the left anterior descending artery and right coronary arteries over time.
- Morbidity and mortality rates are highest if the aneurysm has both a z-score ≥10 and an absolute dimension ≥8 mm ("giant aneurysms").
- Children with KD who are <1 yr or >6 yr are more likely to develop the cardiac sequelae and are least likely to respond to treatment.

FIG. E1 Cheilitis and oral mucosal involvement observed in a child with Kawasaki disease. (Courtesy Joseph F. Merola. From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.)

FIG. E2 Polymorphous, exanthematous eruption seen in a patient with Kawasaki disease. (Courtesy Joseph F. Merola. From Callen JP et al: *Dermatological signs of systemic disease,* ed 5, Philadelphia, 2017, Elsevier.)

BOX E2 Cardiac Abnormalities in Kawasaki Disease

Acute Stage
- Pericardial effusion
- Decreased myocardial function
- Mitral regurgitation
- Enlargement (ectasia) of coronary arteries
- Arrhythmia (rare)

Subacute Stage
- Coronary aneurysms, irregularity, ectasia
- Significant mitral or aortic regurgitation, or both (rare)
- Coronary aneurysm rupture (very rare)
- Myocardial infarction (rare)

Convalescent Stage
- Persistent coronary aneurysms
- Regressed coronary aneurysms (residual fibrosis)
- Coronary artery stenosis
- Coronary aneurysm rupture (very rare)
- Myocardial infarction (rare)

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

- Cervical lymphadenopathy is the most commonly absent physical manifestation in atypical KD, followed by exanthem and then extremity changes.
- Oral mucosal changes are the most common manifestations of KD, affecting approximately 90% of cases (either typical or atypical).
- Sensitivity to light, uveitis, as well as nonexudative conjunctivitis may develop.

BOX E3 Associated Noncardiac Features of Kawasaki Disease

Musculoskeletal System
- Arthritis or arthralgia

Central Nervous System
- Aseptic meningitis
- Facial nerve palsy
- Marked irritability
- Sensorineural hearing loss

Gastrointestinal System
- Hydrops of gallbladder
- Abdominal pain, diarrhea
- Hepatic dysfunction, obstructive jaundice
- Pancreatitis

Genitourinary System
- Urethritis, meatitis

Respiratory System
- Perihilar infiltrates or pulmonary nodules
- Preceding respiratory illness

Other
- Erythema and induration of bacille Calmette-Guérin vaccine site
- Anterior uveitis (mild)
- Desquamating groin rash
- Flare of atopic dermatitis or psoriasis
- Peripheral gangrene (young infants)

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

- Redness and induration can be seen at the site of prior bacille Calmette-Guérin (BCG) inoculation.
- Beau lines (transverse lines across the nails), diarrhea, acute myocarditis, cough, rhinorrhea, dyspnea, arthralgia, and myalgia may also be seen.
- Aseptic meningitis can develop in 40% of cases.
- Interstitial nephritis, acute renal failure in rare cases, KD shock syndrome, and macrophage activation syndrome can also occur.
- Self-limiting arthritis involving large joints including knees, ankles, and hips was reported in 7.5% to 25% of patients, commonly in the second to third week of illness.
- Associated noncardiac features of Kawasaki disease are summarized in Box E3.

ETIOLOGY

- The cause of KD is still unknown despite decades of research.
- Evidence suggests an infectious etiology precipitating an immune-mediated reaction in genetically susceptible individuals.
- One hypothesis is that tropospheric winds from northeastern China carry the etiologic agent of Kawasaki disease from its source to Japan.

Dx DIAGNOSIS

Diagnosis of KD is made on the basis of clinical features (see "Physical Findings & Clinical Presentation"). The hallmark of KD is fever lasting >5 days. Typically, the clinical signs appear over the course of several days. Laboratory evaluation may be helpful in making the diagnosis in atypical KD. The timely diagnosis and treatment of KD are important in preventing complications, especially cardiac complications.

BOX E4 Laboratory Features of Kawasaki Disease

- Leukocytosis with neutrophilia
- Elevated erythrocyte sedimentation rate
- Elevated C-reactive protein (and other acute-phase reactants)
- Anemia
- Thrombocytosis after week 1
- Sterile pyuria
- Hypoalbuminemia
- Hyponatremia
- Elevated serum levels of aminotransferases and γ-glutamyltransferase
- Plasma lipid abnormalities
- Cerebrospinal fluid pleocytosis
- Synovial fluid pleocytosis

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

DIFFERENTIAL DIAGNOSIS

- Scarlet fever
- Stevens-Johnson syndrome
- Drug eruption
- Henoch-Schönlein purpura
- Toxic shock syndrome
- Measles
- Rocky Mountain spotted fever
- Epstein-Barr virus, adenovirus, echovirus, and enterovirus
- Juvenile rheumatoid arthritis
- Mercury hypersensitivity (acrodynia)
- Leptospirosis

WORKUP

Clinical findings in addition to laboratory and imaging studies are useful in searching for multiorgan system involvement and complications (e.g., cardiac, lung, liver).

LABORATORY TESTS

The diagnostic criteria do not include any laboratory tests for KD. However, systemic inflammation is characteristic of KD and evidence of systemic inflammation is helpful for the diagnosis of cases suspicious for atypical KD. Laboratory features of Kawasaki disease are summarized in Box E4.

- Complete blood count commonly shows leukocytosis with neutrophil predominance, normochromic normocytic anemia, and thrombocytosis, which usually rises by the second week.
- Abnormal liver function tests are found: Elevated transaminases (hepatic congestion), elevated bilirubin (gallbladder hydrops), and low albumin.
- Inflammatory markers will be increased in KD. If erythrocyte sedimentation (ESR), C-reactive protein (CRP), and platelet count are normal after 7 days of illness, KD is an

unlikely diagnosis. Ongoing inflammation is manifested by:

1. Elevated ESR often ≥40 mm/hr and not uncommonly elevated to levels of >100 mm/hr.
2. Elevated CRP ≥3 mg/dl.

- Thrombocytosis is a characteristic feature of KD but generally does not occur until the second week and peaks in the third week.
- Thrombocytopenia can be seen in the first or second weeks of illness; however, it can be a sign of consumptive coagulopathy (disseminated intravascular coagulation) and a risk factor for development of coronary artery abnormalities.
- Hyponatremia is associated with increased risk of coronary aneurysms.
- Urinalysis may show sterile pyuria.
- Impaired serum lipid profiles with decreased high-density lipoproteins (HDL) and elevated triglycerides and low-density lipoproteins (LDL) can occur.
- Cerebrospinal fluid (CSF) with increased white cell count and a mononuclear cell predominance without elevated CSF protein or glucose is found.
- Arthrocentesis of joints usually demonstrates purulent-appearing fluid with 125,000 to 300,000 white cells/mm^3, normal glucose level, and negative gram stain and cultures.
- The discovery of a 13-transcript gene expression signature distinguished patients with KD from others with bacterial, viral, and inflammatory illnesses and provides hope for development of a diagnostic test that will allow earlier detection of KD.

IMAGING STUDIES

- ECG changes including arrhythmias, abnormal Q waves, prolonged PR and/or QT intervals, occasionally low voltage, and ST-T wave changes can be seen.
- Chest radiograph may reveal pulmonary infiltrates. Cardiomegaly may also be present.
- Echocardiogram is the mainstay of diagnosis of KD. It is recommended at the time of illness and repeated in 1 to 2 weeks and then again 4 to 6 weeks after treatment (Class IB indication) for uncomplicated KD. Echocardiogram should include careful assessment of the coronary arteries for size and aneurysms, mural or intraluminal thrombi, effusions, valve function, and myocardial function.
- Patients with complicated KD or evolving coronary artery abnormalities (Z score >2.5) detected during acute illness should have echocardiographic evaluation repeated at least twice per week until luminal dimensions have stopped progressing, to determine risk for and presence of thrombosis (Class IB).
- A monthly echocardiogram until the third month after illness onset is recommended because failure to escalate thromboprophylaxis in time with the rapid expansion of aneurysms is the primary cause of morbidity and mortality (Class IIa).
- With respect to cardiovascular testing during long-term follow-up, echocardiographic measurements of the coronary artery become less reliable as patients grow. For that reason, advanced imaging techniques, such as computerized tomographic angiography (CTA) and magnetic resonance angiography (MRA), are becoming more popular.
- Intravascular ultrasound can assess for luminal irregularities of the coronary arteries.
- Exercise testing with myocardial perfusion studies can be done to assess for coronary blood flow and the presence of myocardial ischemia.

BOX E5 Treatment of Kawasaki Disease

Acute and Subacute Stages

- IVIG 2 g/kg infusion over 10 to 12 hours *plus* aspirin 80 to 100 mg/kg per day in four divided doses (until patient is afebrile at least 3 to 4 days; some recommend until 14th day of illness); then 3 to 5 mg/kg once daily for 6 to 8 weeks.
- IVIG may be repeated if fever persists or recurs together with at least one classic sign of disease and/or elevated C-reactive protein level.
- For patients thought to be at particularly high risk of coronary complications, an adjunctive course of corticosteroid may be considered, although optimal dosing and duration are unclear.

Convalescent Stage

- No coronary abnormalities: No therapy
- Transient coronary abnormalities: Aspirin 3 to 5 mg/kg once daily at least until resolution of coronary abnormalities
- Persistent, small to medium coronary aneurysms: Aspirin 3 to 5 mg/kg once daily
- Giant or multiple small coronary aneurysms: Aspirin 3 to 5 mg/kg once daily, with or without clopidogrel 1 mg/kg/day, with warfarin or low-molecular-weight heparin for most patients
- Coronary obstruction: Thrombolytic therapy, surgical or interventional procedures

IVIG, intravenous immunoglobulin
From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

TREATMENT

The goal of treatment of KD in the acute phase is directed at reducing clinical symptoms and reducing inflammation in the systemic and coronary arteries and preventing arterial thrombosis. Standard treatment, including IVIG and aspirin, is usually effective. The disease may recur. Coronary artery abnormalities are serious sequelae of Kawasaki disease. Long-term therapy in individuals who develop coronary aneurysms is aimed at preventing myocardial ischemia or infarction. Box E5 summarizes treatment of Kawasaki disease.

BOX E6 Rescue Therapy for Patients Not Responding to Standard Therapy

- Persistent or recurrent fever and/or elevated serum CRP levels 36 to 48 hours after primary therapy
  1. Repeat 2 g/kg IVIG
  2. Failure of two doses of IVIG: Therapeutic options
     a. Third dose of IVIG (2 g/kg) with or without tapering course of prednisone starting at 2 mg/kg
     b. IV methylprednisolone (usually 30 mg/kg daily in three doses) with or without subsequent oral steroid, tapered over 1 to 3 weeks
     c. Infliximab (5 mg/kg) single dose
     d. Cyclosporine (4 to 8 mg/kg daily for 14 to 21 days), usually IV, with monitoring of serum levels and dosing adjustments
     e. Methotrexate orally (10 mg/m^2) × 1 or 2 doses

CRP, C-reactive protein; *IV,* intravenous; *IVIG,* intravenous immunoglobulin
From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

Box E6 describes rescue therapy for patients not responding to standard therapy.

ACUTE GENERAL Rx

- IV immunoglobulin (IVIG) with high-dose aspirin is the treatment of choice in children diagnosed with complete KD or suspected KD, and ideally should be given within the first 10 days of the illness.
- IVIG is given as 2 g/kg over 10 to 12 hr as a single infusion with high-dose ASA of 80 to 100 mg/kg/day (antiinflammatory dosing) divided into four doses.
- High-dose ASA is given until the patient is afebrile for 48 to 72 hours. Low-dose ASA of 3 to 5 mg/kg/day (antithrombotic dosing) in a single daily dose is given until the followup echocardiogram at 6 to 8 weeks is normal, or it is continued indefinitely if coronary artery abnormalities exist.
- IVIG should not be administered beyond the tenth day of illness in absence of fever, significant elevation of inflammatory markers, or coronary artery abnormalities.
- IVIG infusion results in ESR elevation. CRP is not affected by IVIG and can be used to follow disease activity.
- NSAIDs (e.g., ibuprofen) are not effective in the treatment of KD and may be harmful due to their involvement in the cyclooxygenase pathway.
- Single-dose methylprednisolone should not be administered with IVIG as routine primary therapy for patients with KD (Class IIIB).
- Approximately 10% to 20% of patients develop recrudescent or persistent fever. If fever persists beyond 36 hours after completion of IVIG, patients are considered IVIG resistant.
- A second dose of IVIG 2 g/kg IV over 8 to 12 hr should be considered at least 36 hr after

the end of the first IVIG infusion (Class IIB) in IVIG-resistant patients. Most experts recommend withholding glucocorticoids unless fever persists after at least two courses of IVIG. Administration of pulse dose methylprednisolone 20 to 30 mg/kg intravenously for 3 days with or without subsequent course and taper of oral prednisone may be considered as an alternative to a second IVIG infusion for retreatment in patients with recurrent or recrudescent fever.
- Administration of a longer course of tapered corticosteroids (2 to 3 weeks), together with IVIG and ASA, may be considered for treatment in IVIG-resistant patients (Class IIB).
- Other therapies including urinary trypsin inhibitor (ulinastatin), pentoxifylline, infliximab (monoclonal antibody against tumor necrosis factor-α), etanercept, plasma exchange, abciximab (platelet glycoprotein IIb/IIIa receptor inhibitor), and immunosuppressive agents such as cyclosporine A have been used, but data are limited.
- Infliximab may be considered as an alternative to a second IVIG infusion or corticosteroid infusion in IVIG-resistant patients.
- Cyclosporine may be considered for patients in whom a second IVIG infusion, infliximab, or steroids have failed.
- Immunomodulatory monoclonal antibody therapy (except TNF-α blockers), cytotoxic agents and plasma exchange may be considered in those who are highly refractory.
- Patients with giant coronary artery aneurysms (>8 mm diameter) have a higher risk of coronary artery thrombosis. Aggressive systemic anticoagulation with either low-molecular-weight heparin or warfarin for an international normalized ratio (INR) target of 2.0 to 3.0 and antiplatelet therapy with ASA is needed to improve outcomes and prevent thrombosis within the aneurysm and MI.
- Most patients with moderate to large aneurysms should be maintained on a second antiplatelet agent.
- Acute coronary thrombosis should be managed with thrombolytic agents under cardiology supervision.

CHRONIC Rx

- All patients with a history of coronary artery aneurysm require lifelong surveillance to prevent coronary thrombosis and to treat myocardial ischemia and associated complications.
- Based upon the size of the aneurysm and the age of the patient, other anticoagulation and antiplatelet therapy may be added.
- Coronary revascularization (surgical or percutaneous) is performed for symptoms of angina or evidence of a significant territory of inducible ischemia on stress testing.

NONPHARMACOLOGIC THERAPY

- Emollient creams for peeling skin and balms for fissured lips
- Salt restriction in patients with congestive heart failure
- Oxygen in selected patients

DISPOSITION

- Mortality rate of children with KD is 0.5% to 2.8%, usually from coronary aneurysm thrombosis and MI.
- Death usually occurs in the third to fourth week of the illness.
- Before the use of IVIG, 25% of all patients with KD developed coronary artery aneurysms; this has fallen to 3% to 5% with the use of IVIG.
- Despite treatment with IVIG, 20% of children develop transient coronary artery dilation in the proximal LAD or proximal RCA, 5% develop coronary artery aneurysms, and 1% develop giant aneurysms.
- 50% of coronary artery aneurysms return to normal lumen diameter by 1 to 2 yr after onset of illness.
- Aspirin in high dose decreases the coronary artery involvement to <5% from 25%.
- IVIG has also been shown to improve left ventricular function during the acute stages of the disease.
- Risk factors for the development of coronary aneurysms or giant coronary aneurysms 8 mm or greater are:
  1. Fever lasting >10 days.
  2. Age <1 yr or >6 yr.
  3. Male.
  4. Recurrence of fever.
- A subset of genetically susceptible children (<25%) will suffer irreversible damage to the coronary arterial wall.
- Recurrence is in about 1% to 3% of cases most commonly within 1 yr of the initial occurrence.
- Aspirin should be discontinued upon exposure to varicella or influenza to decrease the risk of developing Reye syndrome.
- Measles, mumps, and varicella immunizations should be deferred for 11 mo after receiving high-dose IVIG.

REFERRAL

Multiple specialists may be consulted to assist in the diagnosis of KD, including dermatology, rheumatology, and infectious disease. Cardiology consultation is recommended in any patient with cardiac involvement and in the long-term follow-up of patients with KD. For patients who are pregnant or considering pregnancy, referral should be made to a high-risk obstetric service.

PEARLS & CONSIDERATIONS

COMMENTS

- The mechanism of action of IVIG therapy for KD remains unknown. Mechanism of action includes modulation of cytokine production, neutralization of toxins or other pathogenic agents, augmentation of regulatory T-cell activity, antibody synthesis suppression, and antiidiotypic antibody provision.
- Failure of corticosteroids suggests that the inflammatory response is different compared with other vasculitic conditions.
- Live vaccine (varicella, measles) administration is suggested to be postponed for 11 mo in children treated with IVIG because it interferes with vaccine immunogenicity.

PREVENTION

- Without a known etiologic agent for KD, primary prevention is not possible.
- Thrombosis leading to MI in a stenotic or aneurysmal coronary artery is the leading cause of death in these children and occurs most often in the first yr after illness onset. Therefore, serial imaging and occasionally stress testing are necessary in patients with significant coronary artery abnormalities (by echocardiography when possible, occasionally by CT coronary angiography or invasive angiography if other imaging is inadequate).

BASIC INFORMATION

DESCRIPTION

Keloid may be defined as a benign growth of dense fibrous tissue developing from an abnormal healing response to cutaneous injury, extending beyond the original borders of the wound or inflammatory response (Fig. E1).

In 1806, Alibert used the term *cheloide,* derived from the Greek *chele,* meaning crab's claw, to describe lateral growth of tissue into unaffected skin.

ICD-10CM CODE
L91.0 Hypertrophic scar

EPIDEMIOLOGY & DEMOGRAPHICS

- Keloid is seen 5 to 15 times more often in pigmented ethnic groups than in whites.
- Its prevalence is 16% in blacks and Hispanics.
- The highest incidence is seen in the second decade of life.
- It affects both sexes equally.
- Combined incidence of keloid and hypertrophic scar ranges from 40% to 70% after surgery to up to 91% after burns.

ETIOLOGY

- Wounds from trauma, surgery, or body piercing (Fig. E2)
- Burns
- Other injuries such as insect bites, vaccination, folliculitis, or acne
- Rarely can be spontaneous without obvious injury
- Familial predisposition seen in some patients

RISK FACTORS:

- Family history of keloids
- Personal history of keloids
- Blacks, Hispanics, and Asians
- Pregnancy
- Puberty
- Patients with blood group A
- Injury over bones

PATHOGENESIS:

- Pathophysiology of keloid is not completely understood.
- Caused by benign dermal fibroproliferation because of disorder in the regulation of cellularity during the wound healing process.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Keloids usually appear within a few months of the injury, in contrast to hypertrophic scars, which develop within a few weeks. At times, it could take up to 1 yr to appear because the growth is slow.
- Keloids are often symptomatic in the early stages. Common complaints are pruritus, burning, pain, and tenderness.
- Keloids are commonly seen on the shoulders, sternum, upper back, nape of neck, ear lobes, mandibular border, and cheek. Hands and feet are often spared.
- Skin lesions vary from papules to nodules to large tuberous lesions (Fig. E3). They have the normal skin color most of the time with well-defined borders. Early on they can appear erythematous; older lesions may be hypopigmented or hyperpigmented. They can be firm to hard in consistency with smooth surface and are tender to touch. Hair follicles are absent in keloids.
- Unlike with hypertrophic scar, in keloids, the scar extends beyond the margin of the initial wound.

FIG. E1 Keloids. An abnormal reparative reaction to skin injury, keloids are characterized by proliferation of fibroblasts and collagen that extends beyond the margins of the original wound. (From Zitelli BJ, Davis HW: *Atlas of pediatric physical diagnosis,* ed 5, Philadelphia, 2007, Mosby.)

DIAGNOSIS

Workup is usually not necessary because it is a clinical diagnosis.

Biopsy is usually avoided because it may increase the keloid size. When biopsy is done, the histology shows randomly organized large collagen fibers in a dense connective tissue matrix. In fact, both major components of extracellular matrix, collagen and glycosaminoglycans, are increased.

DIFFERENTIAL DIAGNOSIS

- Hypertrophic scar
- Dermatofibroma
- Dermatofibrosarcoma protuberance
- Desmoid tumor
- Foreign body granuloma
- Scar with sarcoidosis
- Lobomycosis

TREATMENT

- There is no universally accepted treatment protocol. Prevention is the best strategy.
- Combination treatment is most effective.
- Surgical excision using cold knife followed by intralesional steroids is the preferred method.
- Treatment outcome is the best when it is initiated shortly after the keloid formation.
- Different treatment options include:
  1. Unlike with hypertrophic scars, surgery alone is associated with a 55% to 100% recurrence rate in patients with keloids. Results are significantly better when it is followed by intralesional steroids, radiotherapy, pressure therapy, or silicone application. Both complete and near-total excision has been advocated. Few recommend core extirpation. Use of Z-plasties or any wound-lengthening techniques is strongly discouraged.
  2. Intralesional steroid every 2 to 4 wk is administered either alone or following surgery. Duration of treatment depends on the treatment response. Triamcinolone is the most studied steroid and is used at a concentration of 10 to 40 mg/ml. Higher concentration is used for denser, more recalcitrant lesions, and those located in trunks or extremities. It could be used in combination with lidocaine to reduce the discomfort. A 27- to 30-gauge needle is used for its administration. To distribute the suspension evenly, it should be injected while continuously advancing the needle. No more than 20 to 30 mg of the drug is used during each treatment. Liquid nitrogen is applied to the injection briefly for 2 to 4 seconds about 10 to 15 min before steroid injection for better dispersal of the steroid and to minimize deposition into surrounding

FIG. E2 Keloid of ear lobe after piercing. (From Kliegman RM et al: *Nelson textbook of pediatrics,* Philadelphia, 2011, Saunders.)

FIG. E3 Extensive keloids. (From James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, Saunders.)

normal tissue. Hypopigmentation, skin atrophy, ulceration, and telangiectasia are the side effects associated with this treatment.

3. Cryotherapy has been used for smaller lesions. When this treatment is chosen, the entire lesion is treated with two to three freeze-thaw cycles of 30 seconds' duration each. Most lesions need 2 to 10 treatment sessions at 4-wk intervals. Pain and hypopigmentation are the main adverse events.
4. Silicone gel sheeting or cushioning can prevent keloids from recurring after surgery. These are applied as soon as reepithelialization is achieved and are worn for at least 12 hr/day for 2 to 4 mo.
5. Application of pressure by compression devices has been advocated in the treatment of keloids. These compression treatments include button compression, pressure earrings, pressure gradient garments, ACE bandages, elastic adhesive bandages, compression wraps, Spandex or Elastane bandages, and support bandages. About 24 to 40 mm Hg of pressure must be maintained. It must be instituted for long periods (>23 hr/day for 6-12 mo) before significant effect can be achieved. Unfortunately, many parts of the body are not amenable to this pressure. Patient discomfort frequently reduces compliance.
6. Radiation after surgery can also reduce the recurrence rate. X-rays of 700 to 1500 cGy in fractions over five to six treatments are the most frequently used treatment. Radiation is usually initiated within 10 days, preferably within 24 hr of surgery. It is avoided in pediatric and pregnant patients. At times, brachytherapy with interstitial iridium 192 is used. Most physicians use radiation only for keloids over the extremities. The reported risk of radiation-induced malignancy is theoretical.
7. 5-Fluorouracil can be used as an individual agent, after surgery, or in combination with intralesional steroids. Weekly injection of 0.5 to 2 ml at a 50 mg/ml concentration of 5-fluorouracil for 12 wk is the recommended dose.
8. Superiority of laser use to simple excision currently has not been demonstrated.
9. Topical 5% imiquimod cream has some role when used following surgery locally every night for a minimum of 2 mo.
10. Other treatments include Cordran tape, bleomycin, interferon, vitamin A, nitrogen mustard, antihistamines, zinc, tacrolimus, sirolimus, allantoin, botulinum toxin, colchicine, salicylic acid, calcipotriol, NSAIDs, d-penicillamine, relaxin, quercetin, dinoprostone, doxorubicin, ACE inhibitors, hyaluronidase, pentoxifylline, tranilast, mitomycin-C, tamoxifen, silver sulfadiazine, onion extract, vitamin E, intralesional verapamil.

FOLLOW-UP

Because of the high risk of recurrence, a follow-up of at least 12 mo is necessary to fully evaluate the effectiveness of therapy.

PREVENTION

- Avoid nonessential surgery such as body piercing, which carries a high risk for keloid formation.
- LASIK eye surgery and CO_2 laser resurfacing should be avoided in patients with a tendency for keloids.
- Use a laparoscopic approach when surgery is needed.
- Avoid making incisions over joint spaces or over midchest and ensure that they follow skin creases.
- Handle tissue gently during surgery.
- Ensure good hemostasis intraoperatively.
- Use tension-free primary wound closure.
- Use monofilament, synthetic permanent sutures.
- Use adhesives instead of sutures when possible for closure of wounds.
- Compressive pressure dressing is preferred in high-risk patients following surgery.
- Avoid wound infection.
- Avoid tattoos.
- Aggressively treat inflammatory acne.

COMPLICATIONS

- Psychological effects secondary to disfigurement.
- Contracture from keloids may result in loss of function if overlying a joint.

PROGNOSIS

- Unlike hypertrophic scars, keloids do not regress with time. However, they may continue to expand in size for decades.
- Regardless of the type of treatment, there is a high recurrence rate.
- Keloids never become malignant.

Keloids (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

Klinefelter syndrome is a congenital disorder in which a 47,XXY chromosome complement is associated with hypogonadism and infertility.

SYNONYM

47,XXY Hypogonadism

ICD-10CM CODE
Q98.4 Klinefelter syndrome, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 1 in 500 men (most common sex chromosome disorder)
GENETICS: The most common mosaic complement is 46,XY/47,XXY. 47,XXY karyotypes 48,XXYY, 48,XXXY, and 49,XXXXY have been reported. The manifestations vary in severity by patient (Table E1). This sex chromosome mosaicism is believed to account for the variable presentation. Fertility, although very rare, has been reported in men with Klinefelter syndrome.

TABLE E1 Clinical Features of Klinefelter Syndrome

Karyotype	47,XXY
Inheritance	Sporadic; associated with advanced maternal age; nondisjunction during first or second meiotic division in either parent (67% maternal, 33% paternal); mitotic nondisjunction
Genitalia	Male
Wolffian duct derivatives	Normal
Müllerian duct derivatives	Absent
Gonads	Small, firm testes; seminiferous tubule dysgenesis; azoospermia; Leydig cell hyperplasia
Habitus	Poor to normal virilization at puberty: Gynecomastia; disproportionately long legs
Hormone profile	Testosterone levels variable but usually decreased; increased levels of plasma LH and FSH postpubertally

FSH, Follicle-stimulating hormone; *LH*, luteinizing hormone.
From Larsen PR et al: *Williams textbook of endocrinology*, ed 10, Philadelphia, 2003, Saunders.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Classic triad: Small firm testes, azoospermia, and gynecomastia.
- Prepubertal: Small testes; gonadal volume <1.5 ml is a result of loss of germ cells before puberty.
- Postpubertal: Gynecomastia (periductal fat growth) with small, firm testes. Exaggerated growth of the lower extremities results in a decreased crown-to-pubis/pubis-to-floor ratio. There are diminished strength, diminished ability to grow a full beard or mustache, and infertility. Decreased intellectual development and antisocial behavior are believed to occur with high frequency.

ETIOLOGY

- Several postulated mechanisms: Nondisjunction during meiosis and mitosis and anaphase lag during mitosis or meiosis
- Reason: Maternal age
  1. The incidence of Klinefelter syndrome rises from 0.6% when the maternal age is ≤35 yr to 5.4% when the maternal age is >45 yr.
  2. Of note, the extra X chromosome has a paternal origin as often as a maternal origin.

DIAGNOSIS

- Markedly elevated follicle-stimulating hormone levels.
- Total plasma testosterone levels are decreased in 50% to 60% of patients.
- Free testosterone levels are decreased.
- Plasma estradiol is increased, stimulating the increase in levels of testosterone-binding globulin with resultant decrease in the testosterone/estradiol ratio, which is thought to be the cause of gynecomastia.

LABORATORY TESTS

- Normal to low serum testosterone
- Increased sex hormone–binding globulin (acts to further suppress any available free testosterone)
- Normal to increased estradiol (a result of augmented peripheral conversion of testosterone to estradiol)
- Testis biopsy shows azoospermia, Leydig cell hyperplasia, hyalinization, and fibrosis of the seminiferous tubules. Mosaics may have focal areas of spermatogenesis and, on rare occasions, sperm may appear in the ejaculate. The extra X chromosome is the pivotal factor controlling spermatogenesis and also affects neuronal function directly, leading to the behavioral abnormalities related to decreased IQ
- Buccal smear: One sex chromatin body
- Prepubertal males: Gonadotropin levels are normal
- Postpubertal males: Gonadotropin levels are elevated even when the testosterone level is normal
- Disease associations:
  1. Malignancies: Breast cancer (20 times >XY men and 20% the rate of occurrence in women), nonlymphocytic leukemia, lymphomas, marrow dysplastic syndromes, extragonadal germ cell neoplasms
  2. Autoimmune disorders: Chronic lymphocytic thyroiditis, Takayasu arteritis, taurodontism (enlarged molar teeth), mitral valve prolapse, varicose veins, asthma, bronchitis, osteoporosis, abnormal glucose tolerance testing, diabetes, varicose veins

TREATMENT

- Revolves around three facets of Klinefelter syndrome:
  1. Hypogonadism: Androgen replacement in the form of testosterone
  2. Gynecomastia: Cosmetic surgery
  3. Psychosocial problems: Androgen therapy and educational support
- After extensive genetic counseling, intracytoplasmic sperm insertion has been used to treat infertility with limited success in mosaic men

PEARLS & CONSIDERATIONS

COMMENTS

- Androgen therapy should not be used in the case of severe mental retardation
- Rule out breast and prostate cancer before initiating or continuing androgen therapy
- Androgen therapy will not improve fertility; it may suppress any spermatogenesis that is taking place within the testes
- Other causes of primary hypogonadism:
  1. Myotonic muscular dystrophy
  2. Sertoli cell–only syndrome
  3. Kartagener syndrome
  4. Anorchia
  5. Acquired hypogonadism

Klinefelter Syndrome (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

Korsakoff Psychosis

BASIC INFORMATION

DEFINITION

Korsakoff psychosis (KP) is a disorder of declarative learning and memory that results from thiamine deficiency, largely (90%) secondary to chronic alcohol abuse in industrialized nations. It is classically, but not always, seen following the presentation of Wernicke encephalopathy (see "Wernicke Syndrome").

SYNONYMS

Korsakoff syndrome
Wernicke-Korsakoff syndrome
Alcoholic polyneuritic psychosis
KPF

ICD-10CM CODE

F10.96 Alcohol use, unspecified with alcohol-induced persisting amnestic disorder

EPIDEMIOLOGY & DEMOGRAPHICS

- The incidence of KP is declining as a result of improved patient nutrition and awareness by health professionals
- More common in males
- Age of onset evenly distributed between ages 30 and 70 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Impaired anterograde memory as a core feature, and commonly retrograde memory is impaired to a varying extent as well.
- Remote memory is relatively less impaired on neuropsychiatric testing.
- Confabulation (the fabrication of false memories to fill memory gaps) is common.
- Severe declarative amnesia and concomitant deficits in executive function result in compromised autonomy.

ETIOLOGY

KP is the result of thiamine deficiency. Thiamine deficiency is commonly seen in chronic alcoholism and other malnourished populations (anorexia, bariatric surgery, malignancy). It may also occur from prolonged infusion of dextrose-containing fluids without thiamine repletion.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Stroke, trauma, or tumor affecting the temporal lobes or hippocampi
- Cerebral anoxia
- Transient global amnesia
- Dementia of multiple causes

WORKUP

A high index of suspicion should be maintained in chronic alcoholism and malnourished states.

LABORATORY TESTS

- CBC
- Serum chemistries
- Erythrocyte thiamine transketolase concentration before and after replacement with thiamine pyrophosphate

IMAGING STUDIES

MRI brain may show nonspecific T_2 hyperintensities in the diencephalon and mesencephalon but is not pathognomonic. However, MRI/CT may be helpful in ruling out other diagnoses.

TREATMENT

NONPHARMACOLOGIC THERAPY

A supervised environment may be required.

- Acute: Treatment should be initiated in all patients with clinical suspicion of Wernicke encephalopathy (WE). Thiamine supplementation should precede glucose administration in all patients at risk for WE lest they develop Korsakoff syndrome.
- Alcoholics with WE: Treat with 500 mg of thiamine hydrochloride (dissolved in 100 ml of normal saline) infused intravenously over 30 minutes three times daily for 2 to 3 days.
- If a response is observed, continue with 250 mg of thiamine hydrochloride intravenously or intramuscularly daily until clinical improvement ceases.
- Nonalcoholics with WE: Treat with 200 mg of thiamine hydrochloride (dissolved in 100 ml of normal saline) infused intravenously over 30 minutes three times daily for 2 to 3 days.
- Parenteral magnesium must be infused concurrently with thiamine.
- Side effects of parenteral thiamine hydrochloride may include generalized pruritus, transient local irritation or, rarely, anaphylactic or anaphylactoid reactions.

CHRONIC Rx

Recommended oral dose after completed parenteral treatment for WE: Thiamine 30 to 100 mg twice daily for long-term thiamine replacement.

- Individuals with KP rarely recover; therefore, one must consider the need for additional support and supervision within the home versus placement in a long-term care facility.

REFERRAL

- Neurology to confirm the diagnosis and rule out other causes
- Neuropsychiatric testing to assess baseline functioning and further deterioration

PEARLS & CONSIDERATIONS

COMMENTS

- KP is frequently misdiagnosed or underdiagnosed!
- Memory problems may persist even in "recovered" patients.
- Replace thiamine in patients at risk even if clinical symptoms are not evident.
- Prolonged use of dextrose-containing IV fluids without supplemental thiamine may precipitate KP.
- Strengthening of procedural memory and encouragement of procedural learning can help restore some of the patient's autonomy.

BASIC INFORMATION

DEFINITION

Labyrinthitis is a peripheral vestibulopathy characterized by acute onset of vertigo usually associated with nausea and vomiting. It can be associated with hearing loss and gait abnormalities and may be either serous or purulent.

SYNONYMS

Acute labyrinthitis
Acute vestibular neuronopathy
Vestibular neuronitis
Viral neurolabyrinthitis

ICD-10CM CODES

H81.23	Vestibular neuronitis, bilateral
H83.09	Labyrinthitis, unspecified ear
H83.01	Labyrinthitis, right ear
H83.02	Labyrinthitis, left ear
H83.03	Labyrinthitis, bilateral

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Most common cause of prolonged spontaneous vertigo associated with nausea at any age
PREDOMINANT AGE: Any

PHYSICAL FINDINGS & CLINICAL PRESENTATION

CLINICAL PRESENTATION:

- Vertigo, nausea, and vomiting with onset over several hours.
- Symptoms usually peak within 24 hours, then resolve gradually over several weeks.
- During the first day, the patient usually has difficulty focusing the eyes because of spontaneous nystagmus.
- Usually has benign course with complete recovery within 1 to 3 mo, although older patients may have intractable dizziness that persists for many months.

PHYSICAL FINDINGS

- Nystagmus
- Nausea
- Vomiting
- Vertigo worsening with head movement
- Abnormal caloric ENG tests
- May have hearing loss in the affected ear or ears
- Normal otoscopic exam typically
- Normal neurologic exam; may have signs of vestibular loss, such as a positive head thrust test

ETIOLOGY

Symptoms often preceded for 1 to 2 wk by a viral-like illness. Labyrinthitis may be either bacterial or viral and may be either tympanogenic (i.e., resulting from spread of infection into the inner ear from the middle ear, antrum, or petrous apex), meningogenic, or hematogenic from encephalitis or brain abscess. The round window membrane is considered the most likely pathway of inflammatory mediators from the middle to the inner ear that subsequently give rise to labyrinthitis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Acute labyrinthine ischemia (ischemic stroke of the labyrinthine artery)
- Labyrinthine fistula
- Benign paroxysmal positional vertigo
- Ménière disease
- Cholesteatoma
- Drug-induced vestibulocochlear nerve damage
- Vestibulocochlear nerve (cranial nerve VIII) tumor
- Head trauma
- Vertebrobasilar stroke
- Dehiscence of the superior semicircular canal

WORKUP

- Otoscopic examination
- Neurologic examination, with close attention to cranial nerves
- Bedside test of vestibular function, specifically head thrust or head heave test
- Audiogram if symptoms accompanied by hearing loss
- Caloric test if presentation is atypical

LABORATORY TESTS

- Routine laboratory tests are generally not helpful.
- If there is a history of significant emesis, check electrolytes, BUN, and creatinine.

IMAGING STUDIES

- Imaging studies are usually not necessary.
- Gadolinium-enhanced MRI may show enhancement of bony labyrinth. MRI of the brain with and without contrast with fine cuts through the internal auditory canal is indicated if there is an abnormal cranial nerve exam, headache, concern for stroke, or suspicion of cranial nerve VIII nerve tumor.
- Head CT with fine cuts through temporal bones is indicated if there is a history of trauma or suspicion of cholesteatoma.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Reassurance
- Initial bed rest, then encourage increase in activity as tolerated

ACUTE GENERAL Rx

- Treatment is with antiemetics such as promethazine or ondansetron; vestibular suppressants such as the antihistamines meclizine or diphenhydramine; the anticholinergic scopolamine; and the benzodiazepines diazepam or lorazepam. These medications should only be continued for a few days during the acute phase. Some of these medications, especially scopolamine, should be used with caution in the elderly. Methylprednisolone 100 mg per day for 3 days, with slow taper over 3 wk.
- Valacyclovir has not been shown to be helpful.

CHRONIC Rx

- No specific pharmacologic chronic therapy.
- Vestibular rehabilitation is useful for patients with persistent symptoms.

DISPOSITION

Usually does not require hospital admission unless the patient is unable to tolerate oral intake of liquids

REFERRAL

- Refer if symptoms persist or neurologic abnormalities are present.
- Consider vestibular rehabilitation, particularly in the elderly.

PEARLS & CONSIDERATIONS

COMMENTS

Labyrinthitis is a term that usually implies peripheral vestibulopathy associated with hearing loss. The term *vestibular neuronitis* is typically used when hearing is not affected. Despite this technical distinction, many physicians use these terms interchangeably.

Vestibular Neuronitis (Related Key Topic)

AUTHORS: **Michael Pohlen, MD, Joseph S. Kass, MD, JD, FAAN,** and **Sharon S. Hartman Polensek, MD, PhD**

BASIC INFORMATION

DEFINITION

Lactic acidosis (LA) is a life-threatening condition characterized by accumulation of lactate, especially L-lactate, in the body. It represents an imbalance of lactate overproduction or underutilization usually resulting from tissue hypoperfusion and hypoxia (type A LA), or caused by toxins or medication-induced cellular toxicity (type B LA).

SYNONYMS

Lactic acidosis
Hyperlactatemia
LA

ICD-10CM CODE
E87.2 Acidosis

EPIDEMIOLOGY & DEMOGRAPHICS

RISK FACTORS:

- Sepsis
- Liver disease
- Severe anemia
- Severe trauma
- Advanced heart failure
- Cardiogenic shock
- Hypovolemic shock
- Diabetes mellitus
- Seizures
- Vigorous exercise
- Cocaine
- Medications (metformin, salicylates, beta 2 agonists, propofol, nucleoside reverse-transcriptase inhibitors)
- Thiamine deficiency
- Pheochromocytoma

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Shock, dehydration (tachycardia, decreased skin turgor, decreased urine output, hypotension, dry mucous membranes)
- Possible clues or precipitating factors (sepsis, bleeding, intoxication)
- Altered mental status
- Nausea, vomiting, abdominal pain
- Weakness, lethargy
- Tachypnea, rapid shallow breathing caused by acidosis (Kussmaul breathing)

ETIOLOGY

- Table E1 summarizes medication-induced lactic acidosis. Table E2 describes other pathologies associated with lactic acidosis.
- Type A: Related to tissue hypoperfusion or hypoxia, is probably the most common cause of LA.
  1. Sepsis leading to systemic hypotension and microcirculation dysfunction leading to decreased extraction of oxygen and lactate clearance by the peripheral tissues
  2. Shock: Cardiogenic, hemorrhagic and obstructive shock; LA in those conditions is thought to be related to decreased clearance
  3. Regional ischemia, such as acute mesenteric ischemia
  4. Burns
- Type B: Related to toxins, medications and liver dysfunction, alcoholism, malignancy.
  1. Metformin: Patients who are at increased risk of LA are those who are taking metformin and have renal or hepatic dysfunction, cardiac dysfunction, or those who overdose on the medication
  2. Cyanide poisoning, beta 2 agonist excessive use, thiamine deficiency
  3. Seizure

D-lactic acidosis is a rare type of LA that is associated with short bowel syndrome and bacterial overgrowth.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Alcoholic ketoacidosis
- Uremic acidosis
- Diabetic ketoacidosis
- Fulminant hepatic failure

WORKUP

- Laboratory measurement of lactic acid to confirm diagnosis and assess for precipitating factors
- Identification of triggering conditions such as infections (blood cultures, urine cultures, chest radiographs), blood drug and toxins level (alcohol, metformin, cyanide); liver and kidney function tests (hepatitis, acute kidney insufficiency)

LABORATORY TESTS

- Normal lactate level is 2.0 to 2.5 mEq/L.
- LA is defined by serum lactate concentration >4 mEq/L. An elevated blood lactate level is essential for confirmation of the diagnosis.
- Arterial blood gas analysis demonstrates metabolic acidosis usually with PH <7.3 and pCO_2 <40.
- Serum chemistries:
  1. Low serum bicarbonate <15 mEq/L
  2. Large anion gap (AG) metabolic acidosis: AG >12 usually caused by lactate accumulation. A normal AG does not rule out lactic acidosis. Correction of the AG for the effect of serum albumin can improve its sensitivity
  3. Calculate AG: $AG = NA^+ - (Cl^- + HCO_3^-)$
  4. Mixed metabolic disturbances might demonstrate more than only AG acidosis, especially in patients with vomiting, diarrhea, and acute kidney injury

IMAGING STUDIES

- Chest radiography is helpful if chest infection is suspected as a cause of sepsis or cardiogenic or obstructive shock is suspected.
- Abdominal CT scan or ultrasound might aid in the diagnosis if abdominal pain, regional ischemia, or liver failure is suspected as a cause of the lactic acidosis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- The cornerstone of LA treatment is reversing the causative condition.
- Continuous monitoring for patients with LA is warranted, including monitoring of mental status, urine output, and vital signs.
- Lactate levels should be checked every 2 to 6 hr.
- Surgery in the case of regional tissue ischemia or trauma with shock.
- Cardiac assist devices in the case of cardiogenic shock.
- Hemodialysis for drugs or toxins removal (i.e., metformin-induced LA).

ACUTE GENERAL Rx

Pharmacologic treatment consists of:

- Resuscitating the intravascular component with IV crystalloid or colloid solution fluids in cases of shock.
- Sodium bicarbonate IV infusion should be considered only if pH <7.1 and serum bicarbonate level is less than 6 mEq/L. Infusion of 1-2 mEq/L of sodium bicarbonate in a bolus form repeated every 30 to 60 min if the pH is less than 7.1.
- Vasopressor therapy is cases of shock might be required; increasing doses of vasopressor might be needed as the acidosis can blunt the effect of catecholamines. Norepinephrine is generally preferred over dopamine as the initial vasopressor in most types of shock.
- Optimize oxygen delivery: When an inotrope is indicated to improve cardiac output, dobutamine is usually the preferred agent.

DISPOSITION

- Septic shock and lactic acid level >4 mEq/L are associated with a 28% mortality rate.
- There is a clear correlation with increasing lactate level and increased mortality.

REFERRAL

In general, patients with LA should be admitted to the intensive care unit for close monitoring, frequent lactate, chemistries, and arterial blood gas analysis.

PREVENTION

- Aggressive treatment of shock
- Avoidance of metformin in high-risk populations such as patients older than 85 yr and patients with kidney or liver impairment
- Early use of antibiotics in patients with sepsis

PEARLS & CONSIDERATIONS

COMMENTS

Hemodialysis is not an effective way of clearing lactate or reversing LA, especially in cases of overproduction and tissue hypoxemia; it could be of value in cases of drug- and toxin-induced LA for removal of the offending agent.

RELATED CONTENT

Diabetic Ketoacidosis (Related Key Topic)

AUTHOR: **Fred F. Ferri, MD**

TABLE E1 Medication-Induced Lactic Acidosis

Condition	Source and/or Mechanism	Associated Clinical Manifestations/Important Clinical Information	Comments
Metformin	Metformin can bind to complex 1 of the mitochondrial electron transport chain. Alternatively, it has been postulated that it blocks gluconeogenesis, decreasing conversion of lactate to glucose.	A mortality of 30% of patients with lactate concentrations >5 mmol/L in the presence of metformin was reported in one study, in comparison with 11% in patients with <5 mmol/L.	Occurs in about 4.3 patients per 100,000 patient-yr. Metformin plasma concentration correlates with plasma lactate levels, pH, and creatinine.
Alcohols			
Ethanol	Metabolized in the liver to acetaldehyde, which can potentially inhibit the ETC. Usually, however, it is not associated with hyperlactatemia unless other causes are present, such as thiamine deficiency or salicylates.	Treatment includes administration of folic acid and thiamine to avoid Wernicke-Korsakoff syndrome.	
Methanol	Methanol is metabolized by hepatic alcohol dehydrogenase to formaldehyde and then rapidly oxidized to formic acid by the cytochrome P450 system. Formic acid is a potent inhibitor of OXPHOS.	Treatment options include: 1. Extracorporeal treatment (modality of choice—intermittent hemodialysis or HD) 2. The administration of an antidote—a competitive inhibitor of alcohol dehydrogenase in the form of ethanol or fomepizole. Methanol is eliminated by renal and nonrenal (presumed respiratory clearance) routes. In the absence of antidote therapy, methanol elimination half-life is 2.3-13.7 hours. HD can be terminated when the methanol concentration is <200 mg/L of 6.2 mmol/L and clinical improvement is observed.	The use of antidotes significantly increases the elimination half-life of methanol to a mean of 54 hours and thus extracorporeal removal may be beneficial to shorten ICU stay. Extracorporeal therapy has been recommended in the following circumstances with grade 1D evidence (level 1 = strong recommendation by experts, D = very low level of evidence): 1. Severe poisoning characterized by coma, seizures, new vision deficits, persistent metabolic acidosis despite adequate supportive measures, serum AG >24 mmol/L. 2. High methanol concentration (>700 mg/L with fomepizole treatment; >600 mg/L with ethanol treatment; >500 mg/L in the absence of antidote); in the setting of altered osmolar gap when methanol level is absent. 3. In the context of impaired renal function.
Ethylene glycol	Similar mechanism as methanol. However, ethylene glycol is metabolized to glycolate. In addition, can cause spurious hyperlactatemia because glycolate can cross-react with lactate in certain blood chemistry analyzers.	Fomepizole can be used in the treatment of ethylene glycol intoxication. The elimination (renal) half-life of ethylene glycol is approximately 16 hours during fomepizole treatment. A ≥50 mg/dl of ethylene glycol concentration has been used to determine the use of HD.	
Propylene glycol	Hyperlactatemia has been reported in patients receiving medications that use propylene glycol as a vehicle (lorazepam, diazepam, diphenylhydantoin, trimethoprim-sulfamethoxazole).	Hyperlactatemia is more frequent in patients with renal or hepatic dysfunction because propylene glycol is metabolized in the liver and kidney. Monitoring serum osmolarity has been recommended to detect potentially toxic levels of propylene glycol.	Commercial preparations of propylene glycol come in a 50:50 mixture of D and L isomers. The D isomer is metabolized to D^- lactate, which is cleared more slowly than L^+ lactate. Accumulation of D^- lactate in the brain has been implicated as the cause of the central nervous system manifestations of propylene glycol toxicity.
β_2-adrenergic receptor agonists	Stimulation of Na^+/K^+-ATPase in skeletal muscle.	Described initially in pregnant women undergoing tocolytic treatment with terbutaline, and in patients with asthma undergoing treatment with β_2-adrenergic receptor agonists.	
Salicylates	Salicylates induce hyperlactatemia by uncoupling OXPHOS and inhibiting the enzymes of the Krebs cycle.	Acidosis decreases renal elimination of salicylates and increases the nonionized fraction, which augments passage through the blood-brain barrier, thus increasing the potential for toxicity.	

Cyanide and nitroprusside	Cyanide combines with cytochrome c and inhibits OXPHOS, thus inducing hyperlactatemia. Nitroprusside infusion can cause cyanide toxicity.	Cyanide poisoning usually occurs as a result of smoke inhalation or in the context of a suicide attempt. Cyanide levels offer little help because of prolonged sample processing time. Cyanide poisoning should be suspected in patients exhibiting hyperlactatemia with neurologic and/or cardiovascular manifestations (i.e., confusion, seizures, coma, hypotension). Cyanide toxicity derived from nitroprusside treatment occurs particularly with prolonged infusions (i.e., >72 hours) and with high doses (>2 mg/kg/min). This also can occur with short infusions of very high doses that deplete thiosulfate stores. The best evaluation for possible toxicity in this setting is clinical (i.e., tachycardia, agitation, seizures) and measurement of blood lactate concentrations. Lactic acidosis can be eliminated by routine addition of sodium thiosulfate in the infusion bag.	
Carbon monoxide	Multiple mechanisms: Carboxyhemoglobinemia alters oxygen transport to the tissues and induces a leftward shift of the oxyhemoglobin curve, thus causing tissue dysoxia. More importantly, however, carbon monoxide binds to cytochromes in the electron transport chain, impairing OXPHOS and contributing to ROS production.	Leading cause of unintentional poisoning worldwide. It occurs most commonly in males, during winter, and often involves heating or cooking appliances. Burn victims are at risk of CO poisoning. CO levels usually do not correlate with symptoms.	Signs of CO poisoning: Neuro: Headache, dizziness, confusion, blurry vision, syncope, seizures, incontinence, coma (neuronal excitability $K_{v2.1}$ and Trek-1 channels, activation of soluble guanylyl cyclase and vasodilatation) Cardiovascular: Hypotension, palpitations, chest pain, myocardial ischemia Lung: Noncardiogenic pulmonary edema (epithelial sodium channel compromise [ENaC] and ROS generation) Abdominal: Nausea, vomiting, abdominal pain (ENaC, ROS generation, increased NO production), LFT elevation Muscle: Rhabdomyolysis (myoglobin binding), rigors (peripheral neuronal hyperexcitability from $Na_{v1.5}$ and $K_{v2.1}$ channels)
Antiretroviral agents	Thought to be caused by mitochondrial toxicity secondary to inhibition of DNA polymerase-γ, which uncouples OXPHOS.	Mild-moderate hyperlactatemia (i.e., 2.5-5 mmol/L) occurs in 25% of patients with human immunodeficiency virus under treatment with nucleoside reverse transcriptase inhibitors (particularly stavudine).	
Propofol	Lactic acidosis occurs secondary to uncoupling of OXPHOS and impaired oxidation of fatty acids.	Hyperlactatemia occurs in the setting of the "propofol infusion syndrome," or PIS, which consists of lactic acidosis, heart failure, rhabdomyolysis, and acute kidney injury.	Usually occurs in patients receiving infusions of propofol exceeding 5 mg/kg/hr for more than 48 hours.

AG, Anion gap; *ATPase,* adenosine triphosphatase; *CO,* carbon monoxide; *ETC,* electron transport chain; *HD,* hemodialysis; *ICU,* intensive care unit; *LFT,* liver function test; *NO,* nitric oxide; *OXPHOS,* oxidative phosphorylation; *ROS,* reactive oxygen species.
From Ronco C et al: *Critical care nephrology,* ed 3, Philadelphia, 2019, Elsevier.

TABLE E2 Other Pathologies Associated with Lactic Acidosis

Condition	Source and/or Mechanism	Associated Clinical Manifestations/Important Clinical Information	Comments
Asthma	Increased lactate production from respiratory muscles. However, the peak of hyperlactatemia occurs while the patient is recovering and thus it is more likely that the mechanism relates to stimulatory effect of β_2 agonists on glycolytic flux.	Initial or delayed hyperlactatemia during status asthmaticus has little prognostic value.	Lactic acidosis develops only in some patients after β_2 agonist treatment. The reason for this selectivity is unknown but may be related to polymorphisms in the β_2 receptor gene.
Acute liver failure	Increase in lactate production from Kupffer cells and the lung. Impaired lactate clearance by hepatocytes. Increased hepatic lactate production from accelerated glycolytic rate.	Common in acute liver failure, consequent to an associated systemic inflammatory response resulting from hepatocellular necrosis.	Hyperlactatemia is unusual if there is no increased lactate production during chronic liver dysfunction. Hyperlactatemia has prognostic importance in this patient population.
Malignancy	Cytokine-mediated stimulation of glycolytic flux in neoplastic cells.	Hypoglycemia results from increased glucose utilization by neoplastic cells or may represent a paraneoplastic syndrome.	More frequent in leukemia or lymphomas but also in solid tumors with liver or bone marrow metastases. Lactic acidosis persists even after correction of hypoglycemia.
Thiamine deficiency	Impairment of PDH because thiamine pyrophosphate is an essential co-factor of PDH. Impairs OXPHOS of pyruvate in the Krebs cycle, which stimulates the glycolytic flux.		Can develop rapidly (days) in critically ill patients because of decreased intake or increased urinary or GI losses.
Cardiopulmonary bypass	Hyperglycemia and the administration of epinephrine, norepinephrine, and dobutamine are associated with hyperlactatemia in this setting. The contribution of tissue hypoperfusion to hyperlactatemia has been challenged: Microdialysis measurements during CPB have shown no association between tissue and plasma lactate. Hyperlactatemia has been shown to occur in patients with no evidence of tissue hypoperfusion. Local lung production after CPB has been found to be a significant contributor to hyperlactatemia. Cytokine-mediated and systemic inflammation resulting from exposure of blood to the extracorporeal circuit.	Patients with polymorphisms in the TNF-β or IL-10 genes experienced postoperative lactic acidosis in one study.	Hyperlactatemia during cardiac surgery is associated strongly with mortality.
Severe hypophosphatemia	Depletion of intracellular ATP and decreased 2,3-diphosphoglyceric acid. Nonanion gap acidosis secondary to impaired tubular reabsorption of bicarbonate.	Severe hypophosphatemia (i.e., phosphate <1.5 mg/dl) can be a cause of hyperlactatemia.	
Congenital	Mutations or deletions in respiratory chain genes or in the pyruvate dehydrogenase complex.	Manifests as episodes of lactic acidosis with neurologic and developmental abnormalities. Suspect a mitochondrial cause if in the absence of hypoxia or sepsis, the patient has muscle weakness, or it is difficult to wean from mechanical ventilation. Other neurologic manifestations include stroke, seizures, dementia, migraines, and ophthalmoplegia.	Usually appears during infancy or early childhood, but some may manifest until adulthood.
D-lactic acidosis	In patients with short bowel syndrome, ingested carbohydrates are malabsorbed and reach the colon undigested, where they are fermented by bacteria into organic acids. This acidifies the colonic milieu promoting overgrowth of gut flora with acid-tolerant mechanisms that produce D-lactate.	Occurs in patients with short bowel syndrome secondary to resection or bypass surgery or with chronic pancreatic insufficiency. Associated with neurologic manifestations—slurred speech, confusion, ataxia, triggered by ingestion of large amounts of carbohydrates lasting hours to days.	Suggestive laboratory findings include anion gap acidosis, increased strong ion gap, normal serum lactate level (analyzers only detect L-lactate). Confirmation is done by the finding of serum D-lactate level >3 mmol/L.
Hypoglycemia	Hypoglycemia is a potent stimulant of the sympathetic nervous system, releasing epinephrine, which increases glycolytic flux in muscle and thus the release of lactate. In addition, in hepatic dysfunction, a minimal amount of glucose is required as an energy source for effective conversion of lactate into glucose through gluconeogenesis.	Patients with chronic renal or hepatic disease.	Hypoglycemia-associated lactic acidosis responds promptly to administration of glucose, in contrast with hypoglycemia resulting from malignancy that does not respond to glucose administration.

Lactose Intolerance PTG

BASIC INFORMATION

DEFINITION

Lactose intolerance is the insufficient concentration of lactase enzyme, leading to fermentation of malabsorbed lactose by intestinal bacteria with subsequent production of intestinal gas and various organic acids, manifesting clinically with diarrhea, abdominal pain, flatulence, or bloating after lactose intake. *Lactose malabsorption* occurs when a substantial amount of lactose is not absorbed in the intestine. *Lactase deficiency* is defined as brush-border lactase activity that is markedly reduced relative to the activity observed in infants.

SYNONYM

Lactose malabsorption
Lactase deficiency
Milk intolerance
Carbohydrate malabsorption

ICD-10CM CODES
E73.9 Lactose intolerance, unspecified
E73.8 Other lactose intolerance

EPIDEMIOLOGY & DEMOGRAPHICS

- Nearly 50 million people in the U.S. have partial or complete lactose intolerance. There are racial differences, with <25% of white adults being lactose intolerant but >85% of Asian Americans and >60% of African Americans having some form of lactose intolerance.
- There are geographic variations: highest in Asians (up to 90%), lowest in northern Europeans (approximately 10%), intermediate in southern Europeans and Middle Eastern populations (up to 40%).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Abdominal tenderness and cramping, bloating, flatulence.
- Diarrhea.
- Symptoms are directly related to the osmotic pressure of substrate in the colon and occur approximately 2 hr after ingestion of lactose.
- Physical examination: May be entirely within normal limits.

ETIOLOGY

- Before it can be absorbed, lactose is cleared to glucose and galactose by the enzyme lactase in the brush border of the small intestine. If the amount of lactase is marginal or its expression is left, lactose intolerance will result.
- Congenital lactase deficiency: Common in premature infants; rare in term infants and generally inherited as a chromosomal recessive trait.
- Secondary lactose intolerance: Usually a result of injury of the intestinal mucosa (Crohn disease, viral gastroenteritis, AIDS enteropathy, cryptosporidiosis, Whipple disease, sprue).
- Acquired primary lactase deficiency (adult-type hypolactasia OMIM # 223100) is the most common form of lactase deficiency worldwide. The decline in lactase activity is a multifactorial process that is regulated at the gene transcription level and leads to decreased biosynthesis, retardation of intracellular transport, or maturation of the enzyme lactase-phlorizin hydrolase.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inflammatory bowel disease
- Irritable bowel syndrome
- Pancreatic insufficiency
- Nontropical and tropical sprue
- Cystic fibrosis
- Diverticular disease
- Bowel neoplasm
- Laxative abuse
- Celiac disease
- Parasitic disease (e.g., giardiasis)
- Viral or bacterial infections

WORKUP

- A detailed dietary history is essential in the evaluation of patients with suspected carbohydrate malabsorption.
- The diagnosis can usually be made on the basis of the history and improvement with dietary manipulation.
- Diagnostic workup may include confirming the diagnosis with hydrogen breath test and excluding other conditions listed in the differential diagnosis that may also coexist with lactase deficiency.

LABORATORY TESTS

- Laboratory evaluation may not be necessary in patients with significant history.
- Lactose breath hydrogen test: A rise in breath hydrogen >20 ppm within 90 min of ingestion of 50 g of lactose is positive for lactase deficiency. This test is positive in 90% of patients with lactose malabsorption. Common causes of false-negative results are recent use of oral antibiotics or recent high colonic enema. Fig. E1 illustrates the role of symptoms in determining the clinical importance of lactose malabsorption.
- The lactose tolerance test is an older and less accurate testing modality (20% rate of false-positive and false-negative results). The patient is administered an oral dose of 1 to 1.5 g of lactose/kg body weight. Serial measurement of blood glucose level on an hourly basis for 3 hr is then performed. The test is considered positive if the patient develops intestinal symptoms and the blood glucose level rises <20 mg/dl above the fasting baseline level.
- Diarrhea associated with lactase deficiency is osmotic in nature with an osmotic gap and a pH <6.5.

IMAGING STUDIES

Imaging studies are generally not indicated. A small bowel series may be useful in patients with significant malabsorption.

TREATMENT

NONPHARMACOLOGIC THERAPY

Management consists of reducing lactose exposure by avoiding milk and milk-containing products or using milk in which the lactose has been prehydrolyzed with lactase. A lactose-free diet generally results in prompt resolution of symptoms. Lactose is primarily found in dairy products but may be present as an ingredient or component of common foods and beverages. Possible sources of lactose include breads, candies, cold cuts, dessert mixes, cream soups, bologna, commercial sauces and gravies, chocolate, drink mixes, salad dressings, and medications. Labels should be read carefully to identify sources of lactose.

ACUTE GENERAL Rx

- Addition of lactase enzyme supplement (Lactaid tablets, Dairy Ease) before the ingestion of milk products may prevent symptoms in some patients. However, it is not effective for all lactose-intolerant patients.
- Lactose-intolerant patients must ensure adequate calcium intake. Calcium supplementation is recommended to prevent osteoporosis.

CHRONIC Rx

Patient education regarding foods high in lactose, such as milk, cottage cheese, or ice cream, is recommended.

DISPOSITION

Clinical improvement with restriction or elimination of milk products

REFERRAL

GI referral for endoscopic procedures if concomitant GI disorders are suspected

PEARLS & CONSIDERATIONS

COMMENTS

- There is great variability in signs and symptoms in patients with lactose intolerance depending on the degree of lactase

deficiency. Most individuals with presumed lactose malabsorption can tolerate 12 to 15 g of lactose or up to 12 oz of milk daily without symptoms.
- Nondairy synthetic drinks (e.g., Coffee-Mate) and use of rice milk are generally well tolerated.

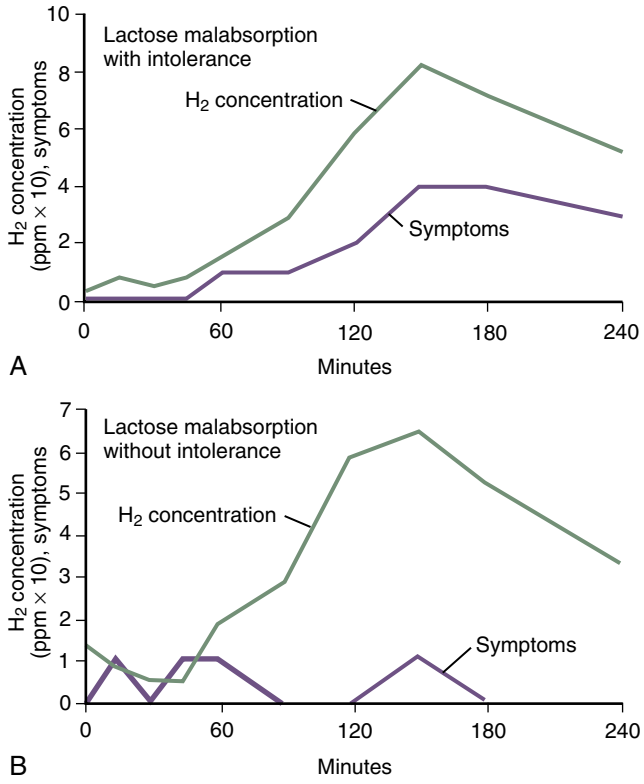

FIG. E1 Graphs illustrating the role of symptoms in determining the clinical importance of lactose malabsorption. Assessment of the clinical relevance of an abnormal lactose hydrogen breath test is made by monitoring abdominal symptoms (bloating, cramps, pain) during the test. Breath hydrogen concentration in parts per million (ppm) and GI symptoms using an arbitrary scoring system for two different patients are plotted on the graphs. **A,** The patient has symptoms associated with an increase in breath hydrogen concentration and therefore can be considered to have lactose intolerance. **B,** The patient has no increase in symptoms, although the breath hydrogen concentration increases considerably, so the patient has lactose malabsorption without lactose intolerance. Lambert-Eaton Myasthenic Syndrome

BASIC INFORMATION

DEFINITION

Lambert-Eaton myasthenic syndrome (LEMS) is an autoimmune disorder of neuromuscular transmission caused by antibodies directed against presynaptic voltage-gated P/Q calcium channels on motor and autonomic nerve terminals. There are two forms: Paraneoplastic (most common) and nonparaneoplastic (autoimmune).

SYNONYMS

Eaton-Lambert syndrome
LEMS

ICD-10CM CODES

G70.80	Lambert-Eaton syndrome, unspecified
G70.81	Lambert-Eaton syndrome in disease classified elsewhere
G73.1	Lambert-Eaton syndrome in neoplastic disease

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Uncertain; estimated at five cases per 1 million persons annually (in U.S.)
PEAK INCIDENCE: Sixth decade
PREVALENCE: Uncertain; estimated at one per 100,000 (in U.S.). Up to 3% of small cell lung cancer (SCLC) patients are estimated to develop LEMS.
PREDOMINANT SEX: Male:female ratio of 2:1

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Weakness with diminished or absent muscle stretch reflexes
- Proximal lower-extremity muscles affected most
- Ocular and bulbar muscles less commonly affected
- Transient strength improvement with brief exercise
- Reflexes may be facilitated by repeatedly tapping the tendon or after brief exercise
- Autonomic dysfunction common (dry mouth [75%], sexual dysfunction, blurred vision, constipation, orthostasis, etc.)

ETIOLOGY

- Antibodies directed against presynaptic voltage-gated P/Q calcium channels are present in most patients. The reduction in calcium influx causes a reduction in presynaptic acetylcholine release at motor and autonomic nerve terminals.
- Paraneoplastic forms, usually associated with SCLC, account for 50% to 70% of patients.
- Autoimmune forms, usually in patients with other autoimmune diseases, occur in 10% to 30% of patients.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Myasthenia gravis: The clinical presentation of Lambert-Eaton myasthenic syndrome is similar to that of myasthenia gravis except that in LEMS, weakness improves with exercise, and hyporeflexia and dysautonomia are present
- Polymyositis
- Primary myopathies
- Carcinomatous myopathies
- Polymyalgia rheumatica
- Botulism
- Guillain-Barré syndrome

WORKUP

Diagnosis is confirmed on basis of characteristic electrodiagnostic (electromyography [EMG]/nerve conduction study [NCS]) findings and detection of serum anti-voltage-gated calcium channel antibodies (90%). EMG reveals: Reduced motor amplitudes with normal sensory studies; >10% decrement in motor amplitudes on slow repetitive nerve stimulation (RNS) at 2 to 5 Hz, with >100% increment on fast RNS (20 to 50 Hz) or immediately after 10 sec of maximum exercise (post-exercise facilitation).

LABORATORY TESTS

Check P/Q calcium channel antibody titers (commercially available).

IMAGING STUDIES

Screen for an underlying malignancy. Presentation with LEMS may precede diagnosis of SCLC by up to 5 yr; hence, CT of the chest or positron emission tomography (PET) scan may be required every 6 to 12 mo to evaluate for SCLC.

TREATMENT

Treatment consists of treating any underlying malignancy or immunosuppression, intravenous immunoglobulin (IVIG), or plasmapheresis when dealing with a purely autoimmune disease.

Amifampridine is the only FDA-approved treatment for symptomatic treatment of LEMS. Amifampridine works by blocking presynaptic potassium channels, thereby increasing presynaptic calcium concentrations and enhancing acetylcholine release.

NONPHARMACOLOGIC THERAPY

Symptomatic treatment for autonomic dysfunction

ACUTE GENERAL Rx

- Amifampridine: Start 15 to 30 mg/day PO divided tid to qid and then increase by 5 mg/day every 3 to 4 days for a maximum of 20 mg per dose and 80 mg/day.
- Plasma exchange (200 to 250 ml/kg over 10 to 14 days) or IVIGs (2 g/kg divided over 2 to 5 days) often produces significant, temporary improvement.
- Prednisone 1.0 to 1.5 mg/kg/day can be gradually tapered over months to minimal effective dose.
- Azathioprine can be given alone or in combination with prednisone. Give up to 2.5 mg/kg/day. If patient is intolerant, can administer cyclosporine up to 3 mg/kg/day instead.

CHRONIC Rx

Treat underlying malignancy if present
Amifampridine for symptoms of weakness

DISPOSITION

- Gradually progressive weakness leading to impaired mobility if untreated
- Clinical remission may occur with chronic immunosuppressive therapy in 43% of cases
- Possible substantial improvement with successful treatment of underlying malignancy

REFERRAL

- Referral to a neurologist is highly recommended because this is a rare disease requiring highly specialized treatment in the context of weighing risk vs. benefit of the different therapeutic options.
- Surgical referral for tumor debulking in paraneoplastic forms necessary.

PEARLS & CONSIDERATIONS

COMMENTS

- Prominent autonomic symptoms (dry eyes, dry mouth, impotence, orthostasis) are often clues to the diagnosis in the appropriate clinical context.
- Many drugs may worsen weakness and should be used only if absolutely necessary. Included are succinylcholine, d-tubocurarine, quinine, quinidine, procainamide, aminoglycoside antibiotics, β-blockers, and calcium channel blockers.

Large Bowel Obstruction

BASIC INFORMATION

DEFINITION

A mechanical or functional interruption of normal intraluminal flow through the colon

SYNONYM

Colorectal obstruction

ICD-10CM CODES
K56.609 Unspecified intestinal obstruction
K56.699 Other intestinal obstruction

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: 73 yr of age, higher in the elderly due to increased rates of colorectal cancer
PREVALENCE: 25% of intestinal obstructions
PREDOMINANT SEX AND AGE: Affects males and females equally, more common in the elderly
RISK FACTORS: Colorectal cancer, prior abdominal surgery, prior colorectal resection, chronic constipation, radiation, diverticulitis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- History:
  1. Patients commonly present with abdominal pain, abdominal distension, and obstipation.
  2. Patients may have nausea and vomiting, but these are very late-presenting symptoms.
  3. Patients may report a history of bloating or constipation prior to the onset of more severe symptoms.
  4. Inquiries should be made concerning recent weight loss or gain, bowel habits, narcotic use, prior surgery, and malignancy.
- Physical exam:
  1. Patient may be tachycardic or febrile from perforation, strangulation, or ischemia.
  2. Exam should include palpation of the abdomen, investigation for umbilical, inguinal and femoral hernias, as well as a rectal exam.
  3. Physical exam findings may include:
     a. Distended, tympanitic abdomen
     b. Nonspecific tenderness to palpation of the lower abdomen
     c. A palpable hernia
     d. Rectal mass or frank blood on rectal exam
  4. If possible, proctoscopy should be performed in the office to evaluate for volvulus or sigmoid mass.

ETIOLOGY

- Colorectal cancer, volvulus, diverticulitis, abscess, adhesions, anastomotic strictures, hernia, fecal impaction, inflammatory bowel disease, ischemic colitis, intussusception, colonic pseudoobstruction, narcotic associated adynamic ileus, sepsis or *C. difficile* infection.
- Box 1 summarizes causes of adult large bowel obstruction.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Colorectal cancer
- Volvulus
- Diverticulitis
- Abdominal abscess
- Abdominal adhesions
- Anastomotic stricture
- Hernia
- Fecal impaction
- Crohn disease
- Ischemic colitis
- Intussusception
- Pseudoobstruction (Ogilvie syndrome)
- Constipation
- Toxic megacolon

WORKUP

- Establish IV access with two large-bore IVs.
- Make the patient NPO.
- Flexible sigmoidoscopy or colonoscopy in stable patients.

LABORATORY TESTS

- Complete blood count with differential
- Basic metabolic panel

IMAGING STUDIES

- Acute abdominal series should demonstrate dilation of the colon (Fig. E1):
  1. Sensitivity 84%
  2. Specificity 72%
- CT abdomen and pelvis imaging is useful to pinpoint the obstruction and possibly identify the etiology (Fig. E2):
  1. Sensitivity 83%
  2. Specificity 93%
- Water contrast enema is useful for evaluating volvulus or distal obstruction cancer:
  1. Sensitivity 96%
  2. Specificity 98%
  3. Occasionally therapeutic

BOX 1 Causes of Adult Large Bowel Obstruction

Mechanical
- Neoplasm
- Volvulus (sigmoid, cecal, transverse colon)
- Diverticulitis
- Cecal bascule
- Intussusception
- Inflammatory bowel disease
- Incarcerated hernia
- Infection (abscess, inflammation)
- Fecal impaction
- Adhesion-related obstruction
- Foreign body

Functional
- Acute toxic or chronic megacolon
- Colonic pseudoobstruction (Ogilvie syndrome)

From Cameron JL, Cameron AM: *Current surgical therapy,* ed 12, Philadelphia, 2017, Elsevier.

TREATMENT

- IV fluid resuscitation:
  1. Consider placing Foley catheter to monitor UOP
- Correction of electrolyte abnormalities
- Nasogastric tube to decompress the GI tract
- Cessation of narcotics and antihistamines

NONPHARMACOLOGIC THERAPY

- Emergent laparotomy for perforation, closed loop obstruction, peritonitis, or ischemia
  1. Placement of loop colostomy
- Rectal cancer: Loop colostomy for cancer, then neoadjuvant chemoradiation
- Colon cancer: Depends on location; Hartmann for sigmoid colon cancer, partial or total colectomy for other colon cancers
- Flexible sigmoidoscopy for colonic decompression of volvulus
- Endoscopic stenting for palliation or as a bridge to surgery

ACUTE GENERAL Rx

Neostigmine for pseudoobstruction

CHRONIC Rx

Not indicated

DISPOSITION

Immediate referral to general surgery and hospital admission

REFERRAL

General surgery

Laryngeal Carcinoma (PTG)

BASIC INFORMATION

DEFINITION

Laryngeal carcinoma is cancer of the larynx, including the vocal cords (glottis), supraglottis, and subglottis.

SYNONYMS

Laryngeal cancer
Head and neck cancer (subsite)

ICD-10CM CODES

D02.0	Carcinoma in situ of larynx
C32.8	Malignant neoplasm of overlapping sites of larynx
C32.9	Malignant neoplasm of larynx, unspecified
D14.1	Benign neoplasm of larynx
D38.0	Neoplasm of uncertain behavior of larynx

EPIDEMIOLOGY & DEMOGRAPHICS

It is estimated that there were 12,410 new cases and 3,760 deaths in 2019 in the U.S. The peak incidence is in the sixth decade, with 80% of cases detected in males. Approximately 60% of cases present as advanced disease (stages III to IV). Compared with Caucasians, African Americans develop laryngeal cancer at a younger age and have a higher incidence and mortality.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Glottis: Early diagnosis possible because of voice change (hoarseness). Any voice change of more than 2 wks' duration should prompt a laryngeal examination.
- Supraglottis:
  1. No early symptoms
  2. Cervical lymphadenopathy
  3. Neck or ear pain
  4. Discomfort and/or pain during swallowing
  5. Later: Hoarseness, dysphagia, airway obstruction
- Subglottis: Even more subtle than supraglottic lesion; the same signs occur, only later in the course.

ETIOLOGY

The following factors are implicated in the development of laryngeal cancer:

- Smoking
- Alcohol intake/abuse
- Diet (red meat)
- Gastroesophageal and laryngopharyngeal reflux
- Chronic laryngitis
- Exposure to textile dust, asbestos, polycyclic aromatic hydrocarbons
- Exposure to radiation
- Human papillomavirus is detected in 20% to 30% cases, but the causative aspects are yet to be determined

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Laryngitis
- Allergic and nonallergic rhinosinusitis
- Gastroesophageal reflux
- Voice abuse leading to hoarseness
- Laryngeal papilloma

TNM STAGING (AJCC EIGHTH EDITION): Primary Tumor:

- T_X: Primary tumor cannot be assessed
- T_{is}: Carcinoma *in situ*

Supraglottic cancers:

- T_1: Tumor limited to one subsite with normal cord mobility
- T_2: Tumor invades mucosa of more than one adjacent subsite (e.g., base of tongue, vallecula, pyriform sinus) without fixation of larynx
- T_3: Tumor is limited to larynx with vocal cord fixation and/or invasion of postcricoid area, pre-epiglottic space, paraglottic space, and/or inner cortex of thyroid cartilage
- T_{4a}: Moderately advanced local disease; tumor invades thyroid cartilage or extends into tissues beyond larynx (trachea, soft tissue of the neck, strap muscles, thyroid, or esophagus)
- T_{4b}: Very advanced local disease; tumor invades prevertebral space, encases carotid artery, or invades mediastinal structures

Glottic cancers:

- T_1: Tumor limited to vocal cord with normal mobility
- T_{1a}: Tumor limited to one vocal cord
- T_{1b}: Tumor involves both vocal cords
- T_2: Tumor extends to supraglottis and/or subglottis and/or impairs cord mobility
- T_3: Tumor limited to larynx with cord fixation and/or invasion of paraglottic space and/or inner cortex of thyroid cartilage
- T_4: T_{4a} and T_{4b}—same as supraglottic staging

Subglottic cancers:

- T_1: Tumor limited to subglottis
- T_2: Tumor extends to vocal cord(s), with normal or impaired mobility
- T_3: Tumor limited to larynx with vocal cord fixation and/or inner cortex of thyroid cartilage
- T_4: T_{4a} and T_{4b}—same as supraglottic staging

Nodal status:

- N_X: Nodes cannot be assessed
- N_0: No regional node metastases
- N_1: Metastasis in a single ipsilateral node <3 cm in size
- N_{2a}: Metastasis in a single ipsilateral node >3 cm but <6 cm
- N_{2b}: Metastasis in multiple ipsilateral nodes none >6 cm in size
- N_{2c}: Metastasis in bilateral nodes none >6 cm in size
- N_{3a}: Metastasis in one or more nodes >6 cm in size
- N_{3b}: Metastasis in any lymph node with clinically overt extranodal extension

Distant metastases:

- M_0: No distant metastases
- M_1: Distant metastases present

Stage grouping:

- Stage I: T_1, N_0, M_0
- Stage II: T_2, N_0, M_0
- Stage III: T_3, N_0, M_0; or T_{1-3}, N_1, M_0
- Stage IVA: T_{1-3}, N_2, M_0
- Stage IVB: Any T, N_3, M_0; T_{4b}, any N, M_0
- Stage IVC: Any T, any N, M_1

WORKUP

- Primary workup includes either biopsy or fine-needle aspiration (FNA) of the presenting lesion or suspected neck lymph node for histopathologic analysis. HPV assessment with p16 immunohistochemical staining and confirmatory in situ hybridization (ISH) testing is not usually indicated unless extension of a primary pharyngeal tumor is suspected.
- Detailed examination of the oral cavity, pharynx, larynx, neck, ears, nose, and cranial nerves should be performed.
- Laryngoscopy and examination under anesthesia are commonly performed.
- Pretreatment evaluation of tumor size, the extent of invasion, and the presence or absence of regional lymph node metastases is critical for planning treatment.
- Laboratory workup can include complete blood count, complete chemistry panel, and thyroid function.
- Staging workup includes CT or MRI imaging (Fig. E1) of the head and neck and a chest x-ray. If locoregional or advanced disease is a consideration, a PET scan is typically completed.

HISTOLOGIC CLASSIFICATION

Epithelial cancers:

- Squamous cell carcinoma
- Superficially invasive cancer
- Verrucous carcinoma
- Pseudosarcoma
- Anaplastic cancer
- Transitional cell carcinoma
- Lymphoepithelial cancer
- Adenocarcinoma
- Neuroendocrine tumors, including small cell and carcinoid

Sarcomas:

- Metastatic or primary

TREATMENT

GENERAL Rx

The guiding treatment principles are focused on definitive cancer-directed therapy, larynx preservation, and voice rehabilitation in all patients.

- Early-stage (T_1 to T_2) patients can be treated with conservative surgery with or without neck dissection. Surgical options include transoral laser microscopic surgery or open conservation laryngeal surgery. Alternatively, definitive radiotherapy is also a curative option.

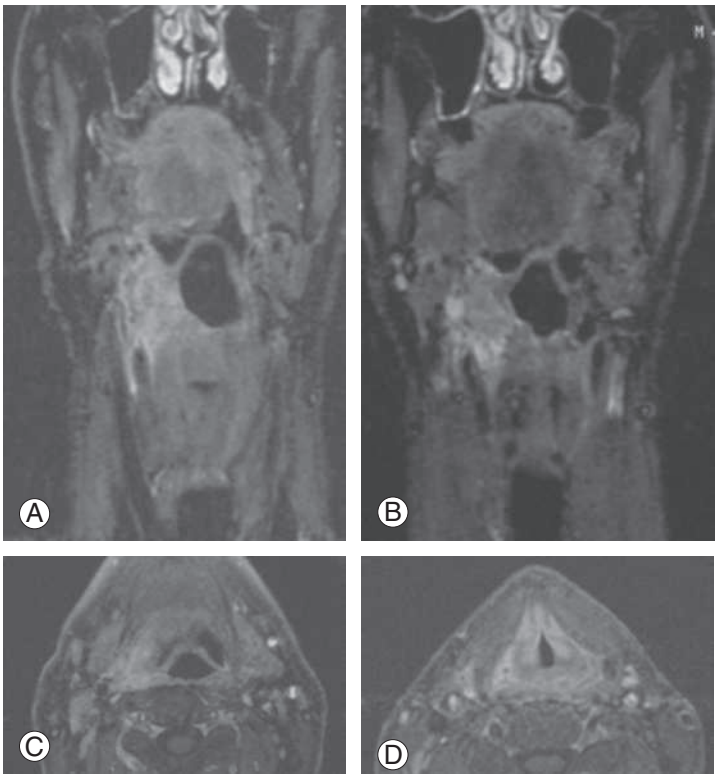

FIG. E1 Carcinoma of the larynx. (A,B) Coronal STIR and **(C,D)** axial T1WI + Gad FS. The coronal images demonstrate the superior and inferior extents while the axial images define the extent more accurately. (From Grant, LA: *Grainger & Allison's diagnostic radiology essentials*, ed 2, Philadelphia, 2019, Elsevier.)

- Intermediate-stage patients can be treated with definitive radiotherapy, supraglottic laryngectomy with neck dissection with or without radiotherapy, or concurrent chemotherapy and radiotherapy.
- Advanced-stage patients are treated with concurrent chemotherapy and radiotherapy as initial therapy; salvage laryngectomy is reserved for cases of treatment failure.

In glottic cancers, early-stage and intermediate-stage cases are treated similarly as above. For advanced cases (T_4), total laryngectomy and neck dissection followed by postoperative radiation with or without chemotherapy in high-risk situations is a standard approach. Concurrent chemotherapy and radiotherapy can be considered for medically inoperable candidates.

Subglottic cancers require a total laryngectomy and neck surgery followed by radiotherapy with or without chemotherapy.

In case of unresectable cancers, the treatment consists of definitive chemotherapy and radiotherapy followed by neck dissection. If hypopharyngeal involvement exists, then laryngopharyngectomy with neck dissection and postoperative radiotherapy with or without chemotherapy is required.

Metastatic cancers:

- Patients who have metastatic cancers or unresectable locoregional recurrences are usually treated with systemic chemotherapy.
- Standard doublet chemotherapy regimens (platinum plus either 5-fluorouracil or a taxane) can be combined with the epidermal growth factor receptor (EGFR)–targeting antibody cetuximab. A recent study has demonstrated the superiority of frontline therapy with platinum plus 5-flurouracil chemotherapy in combination with the checkpoint inhibitor, pembrolizumab.
- In patients who have not received checkpoint inhibitor therapy previously, the use of nivolumab and pembrolizumab has been shown to improve survival outcomes after failure of first-line chemotherapy.

DISPOSITION

- Survival depends upon location of the tumor, with supraglottic cancers typically having better stage-for-stage 5-yr survival rates compared with glottic cancers.
- Voice rehabilitation, including the use of tracheoesophageal prosthesis, is associated with improved quality of life in patients receiving treatment for laryngeal cancers.
- Patients with metastatic cancers have improved outcomes with introduction of targeted therapies and immunotherapy drugs.
- Multiple molecular targets, including tyrosine kinase receptors (such as epidermal growth factor receptor [EGFR], fibroblast growth factor receptor 1 [FGFR1], and Erb-B2 receptor tyrosine kinase 2 [ERBB2]), oncogenes (cyclin-D1 [CCND1], Harvey rat sarcoma viral oncogene homolog [HRAS]), tumor suppressor genes (tumor protein 53 [TP53], neurofibromin 1 [NF1]), and the phosphoinositide 3-kinase (PI3-K) pathway have been identified, which can potentially be utilized as therapeutic targets.

REFERRAL

To multidisciplinary team consisting of an ENT or head and neck physician, radiation oncologist, and medical oncologist

BASIC INFORMATION

DEFINITION

Laryngitis is an acute or chronic inflammation of the laryngeal mucous membranes.

SYNONYM

Lower respiratory tract infection

ICD-10CM CODES
J04.0 Acute laryngitis
J37.0 Chronic laryngitis

EPIDEMIOLOGY & DEMOGRAPHICS

It is a common illness worldwide in both genders and all age groups, but the diagnosis is imprecise and, therefore, statistics are not readily available with respect to incidence and prevalence.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

ACUTE LARYNGITIS:

- Clinical syndrome characterized by the onset of hoarseness, voice breaks, or episodes of aphonia; may also have accompanying sore throat, cough, nasal congestion, and rhinorrhea
- Usually associated with viral upper respiratory infection
- Larynx with diffuse erythema, edema, and vascular engorgement of the vocal folds, and occasionally mucosal ulceration
- In young children subglottis is often affected, resulting in airway narrowing with marked hoarseness, inspiratory stridor, dyspnea, and restlessness
- Respiratory compromise rare in adults

CHRONIC LARYNGITIS: Characterized by hoarseness or dysphonia persisting for longer than 2 wk.

ETIOLOGY

ACUTE LARYNGITIS:

- Most often caused by viruses so treatment consists of supportive measures as outlined in "Nonpharmacologic Therapy" section.
- Studies evaluating the use of antibiotics (erythromycin, penicillin) in acute laryngitis failed to show objective clinical benefit over placebo so they are not routinely recommended. Antibiotics and other antimicrobials may be indicated in cases in which specific treatable pathogens are identified.
- Avoid decongestants because of their drying effect.
- Guaifenesin may be a useful adjunct as a mucolytic agent.
- In gastroesophageal reflux disease (GERD)-associated laryngitis use acid-suppressive therapy (H_2 blockers, proton pump inhibitors) and nocturnal antireflux precautions.

CHRONIC LARYNGITIS:

- Results from any of the following: Tuberculosis, usually through bronchogenic spread; leprosy, from nasopharyngeal or oropharyngeal spread; syphilis, in secondary and tertiary stages; rhinoscleroma, extending from the nose and nasopharynx; actinomycosis; cryptococcosis; histoplasmosis; blastomycosis; paracoccidioidomycosis; coccidiosis; candidiasis; aspergillosis; sporotrichosis; rhinosporidiosis; parasitic infections including leishmaniasis and Clinostomum infection following raw fresh-water fish ingestion.
- Noninfectious causes of both acute and chronic laryngitis include malignancy, voice abuse (singers), GERD, and chemical or environmental irritants such as cigarettes and allergens. Other causes of inflammatory or granulomatous lesions of the larynx include relapsing polychondritis, Wegener granulomatosis, and sarcoidosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Young children with signs of airway obstruction:
  1. Supraglottitis (epiglottitis)
  2. Laryngotracheobronchitis
  3. Tracheitis
  4. Foreign body aspiration
- In adults with persistent hoarseness, consider noninfectious causes of laryngitis as listed previously
- Table E1 summarizes the classification and definition of infectious illnesses involving the larynx and supraglottic and infraglottic regions

WORKUP

- History and physical examination: Diagnosis is usually apparent.
- Laryngoscopy for severe or persistent cases.
- Laryngeal cultures should be performed if a cause other than acute viral infection is suspected.
- Imaging not indicated unless there is evidence of airway compromise. Obtain plain radiographs of neck, anteroposterior and lateral views, to differentiate laryngitis from acute laryngotracheobronchitis or supraglottitis.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Rest the voice.
- Use an air humidifier.
- Ensure adequate hydration. Avoid alcohol and caffeine because of diuretic effect.

ACUTE GENERAL Rx

- Antibiotics and other antimicrobials should generally not be used. They are indicated only when a specific pathogen is isolated; commonly employed antibacterial agents are macrolides; clarithromycin 500 mg by mouth bid for 5 to 7 days or azithromycin 500 mg followed by 250 mg once daily for 4 to 5 days if the cause of laryngitis is found to be *Mycoplasma pneumoniae* or *Chlamydophila pneumoniae* (the new name for what was formerly known as *Chlamydia pneumoniae*).
- Avoid decongestants because of their drying effect.
- Guaifenesin may be a useful adjunct as a mucolytic agent.
- In GERD-associated laryngitis use acid-suppressive therapy (H_2 blockers, proton pump inhibitors) and nocturnal antireflux precautions.

DISPOSITION

Uncomplicated laryngitis is usually benign, with gradual resolution of symptoms.

REFERRAL

- If symptoms persist for >2 wk, refer to otolaryngologist for laryngoscopy.
- Consider referral to gastroenterologist if GERD is suspected.

PEARLS & CONSIDERATIONS

- Most cases of uncomplicated acute laryngitis are viral in origin, and antibacterial agents should not be routinely administered.
- A recent Cochrane analysis in 2013 found no evidence for the use of empiric antibiotics in adults with laryngitis.
- The most difficult clinical challenge is often convincing patients with acute laryngitis that they do not need and will not benefit from antibacterial agents.

Laryngitis (Patient Information)

AUTHOR: **Glenn G. Fort, MD, MPH**

SUGGESTED READING

Reveiz L, Cardona AF: Antibiotics for acute laryngitis in adults, *Cochrane Database Syst Rev Mar* 28(3):CD004783, 2013.

TABLE E1 Classification and Definition of Infectious Illnesses Involving the Larynx and Supraglottic and Infraglottic Regions

Category	Other Terms	Definitions
Supraglottitis	Epiglottitis	Infection of the epiglottis and/or arytena-epiglottic folds and ventricular bands of the base of the epiglottis, resulting in swelling and upper airway obstruction
Laryngitis		Inflammation of larynx resulting in hoarseness; usually occurs in older children and adults in association with common upper respiratory viral infections
Laryngeal diphtheria	Membranous croup, true croup, diphtheritic croup	Infection involving larynx and other areas of upper and lower airway due to *Corynebacterium diphtheriae,* resulting in gradually progressive obstruction of airway and associated inspiratory stridor
Laryngotracheitis	False croup, virus croup, acute obstructive subglottic laryngitis	Inflammation of larynx and trachea most often caused by infection with parainfluenza and influenza viruses
Laryngotracheobronchitis and laryngo-tracheobronchopneumonitis	Membranous laryngotracheobronchitis, pseudomembranous croup	Inflammation of larynx, trachea, and of bronchi or lung or all three; usually similar in onset to laryngotracheitis, but a more severe illness; bacterial infection frequently has causative role
Bacterial croup	Bacterial tracheitis, membranous croup, membranous tracheitis, membranous laryngotracheobronchitis, pseudomembranous croup	Severe form of laryngotracheitis, laryngotracheobronchitis, or laryngotracheobronchopneumonitis due to bacterial infection
Spasmodic croup	Spasmodic laryngitis, catarrhal spasm of the larynx, subglottic allergic edema	Illness characterized by sudden nighttime onset of inspiratory stridor; associated with mild upper respiratory infection without inflammation or fever but with edema in subglottic region

From Cherry JD et al: *Feigin and Cherry's pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

Lead Poisoning PTG

BASIC INFORMATION

DEFINITION

Lead is a potent, pervasive neurotoxicant. Lead poisoning refers to multisystem abnormalities resulting from excessive lead exposure.

SYNONYM

Plumbism

ICD-10CM CODES

T56.0X1A	Toxic effect of lead and its compounds, accidental (unintentional), initial encounter
T56.0X1D	Toxic effect of lead and its compounds, accidental (unintentional), subsequent encounter
T56.0X1S	Toxic effect of lead and its compounds, accidental (unintentional), sequela
T56.0X2A	Toxic effect of lead and its compounds, intentional self-harm, initial encounter
T56.0X2D	Toxic effect of lead and its compounds, intentional self-harm, subsequent encounter
T56.0X2S	Toxic effect of lead and its compounds, intentional self-harm, sequela
T56.0X3A	Toxic effect of lead and its compounds, assault, initial encounter
T56.0X3D	Toxic effect of lead and its compounds, assault, subsequent encounter
T56.0X3S	Toxic effect of lead and its compounds, assault, sequela
T56.0X4A	Toxic effect of lead and its compounds, undetermined, initial encounter
T56.0X4D	Toxic effect of lead and its compounds, undetermined, subsequent encounter
T56.0X4S	Toxic effect of lead and its compounds, undetermined, sequela

EPIDEMIOLOGY & DEMOGRAPHICS

- Lead poisoning is most common in children ages 1 to 5 yr (17,000 cases/100,000 persons). The highest rates are among blacks, those with low income, and urban children.
- In 1991 the Centers for Disease Control and Prevention (CDC) lowered the definition of a safe blood lead level to <10 mcg/dl of whole blood (a blood lead level of 25 mcg/dl was considered acceptable before 1991).
- It is estimated that >15% of preschoolers in the U.S. have a blood lead level >15 mcg/dl.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Findings vary with the degree of toxicity (Table 1). Examination may be normal in patients with mild toxicity.
- Myalgias, irritability, headache, and general fatigue may be present initially.
- Abdominal cramping, constipation, weight loss, tremor, paresthesias and peripheral neuritis, seizures, and coma may occur with severe toxicity.
- Motor neuropathy is common in children with lead poisoning; learning disorders are also frequent.

ETIOLOGY

Chronic, repeated exposure to paint containing lead, plumbing, storage of batteries, pottery, or lead soldering. Concentration of lead is generally highest in lead-based paint on exterior surfaces. Among interior surfaces, windows are most likely to have the highest lead content. Table 2 summarizes common sources of lead.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Polyneuropathies from other sources
- Anxiety disorder, attention deficit disorder
- Malabsorption, acute abdomen
- Iron-deficiency anemia

WORKUP

Laboratory screening: All U.S. children should be considered to be at risk for lead poisoning and should be screened routinely starting at age 1 yr for low-risk children and age 6 mo for high-risk children.

LABORATORY TESTS

- Venous blood lead level: Normal level, <5 mcg/dl; levels of 50 to 70 mcg/dl, indicative of moderate toxicity; levels >70 mcg/dl, associated with severe poisoning
- Mild anemia with basophilic stippling on peripheral smear
- Elevated zinc protoporphyrin levels or free erythrocyte protoporphyrin level
- An increased body burden of lead with previous high-level exposure in patients with occupational lead poisoning can be demonstrated by measuring the excretion of lead in urine after premedication with calcium ethylenediamine tetraacetic acid (EDTA) or another chelating agent

IMAGING STUDIES

- Imaging studies are generally not necessary.
- A plain abdominal film can visualize lead particles in the gut.
- "Lead lines" may be noted on x-ray films of long bones.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Provide adequate amounts of calcium, iron, zinc, and protein in patient's diet.
- Family education on sources of lead exposure and potential adverse health effects.

ACUTE GENERAL Rx

- The use of chelation in cases of acute lead poisoning is guided by the patient's clinical status and the blood lead level (BLL). For children with blood levels of 10 to 19 mcg/dl, the CDC recommends nonpharmacologic interventions (see "Nonpharmacologic Therapy").
- For children with blood levels between 20 and 44 mcg/dl, the CDC recommendations include case management by a qualified social worker, clinical management, environmental assessment, and lead hazard control. Chelation therapy should be considered in children with refractory blood lead levels. Chelation therapy (Table 3) is indicated in children with blood lead levels >45 mcg/dl.
- Succimer (DMSA) 10 mg/kg PO q8h for 5 days then q12h for 2 wk can be used in patients with levels between 45 and 70 mcg/dl.

TABLE 1 Serum Lead Levels and Symptoms

	Symptoms	
Level (μg/dl)	**Adults**	**Children**
10	None	Decreased IQ
		Decreased hearing
		Decreased growth
20	Increased protoporphyrin	Decreased nerve conduction velocity
	No symptoms	Increased protoporphyrin
30	Increased blood pressure	Decreased vitamin D metabolism
	Decreased hearing	
40	Peripheral neuropathies	Decreased hemoglobin synthesis
	Nephropathy	
	Infertility (men)	
50	Decreased hemoglobin synthesis	Lead colic
70	Anemia	Anemia
		Encephalopathy
		Nephropathy
100	Encephalopathy	Death

IQ, Intelligence quotient.
From Marx JA et al: *Rosen's emergency medicine*, ed 8, Philadelphia, 2014, Saunders.

- Edetate calcium disodium (EDTA) and dimercaprol (BAL) are effective in patients with severe toxicity.
- Use of both EDTA and DMSA is indicated in children with blood levels >70 mcg/dl.
- d-Penicillamine (Cuprimine) can also be used for lead poisoning, but it is not FDA approved for this condition.

TABLE 2 Sources of Lead

Paint chips
Dust
Soil
Parent's or older child's occupational exposure (auto repair, smelting, construction, remodeling, plumbing, gun/bullet exposure, painting, e-scrap)
Glazed ceramics
Herbal remedies (e.g., Ayurvedic medications)
Home remedies including antiperspirants, deodorants (litargirio)
Jewelry (toys or parents')
Stored battery casings (or living near a battery smelter)
Lead-based gasoline
Moonshine alcohol
Mexican candies; Ecuadorian chocolates
Indoor firing ranges
Retained bullet fragments
Imported spices (*svanuri marili, zafron, kuzhambu*)
Lead-based cosmetics (kohl, surma)
Lead plumbing (water)
Imported foods in lead-containing cans
Imported toys
Home renovations
Antique toys or furniture

From Kliegman RM: *Nelson's textbook of pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

CHRONIC Rx

- Reduce exposure, remove any potential lead sources.
- Correct iron deficiency and any other nutritional deficiencies.
- Recheck blood lead level 7 to 21 days after chelation therapy.

DISPOSITION

Patients with mild to moderate toxicity generally improve without any residual deficits. The presence of encephalopathy at diagnosis is a poor prognostic sign. Residual neurologic deficits may persist in these patients. Chelation therapy seems to slow the progression of renal insufficiency in patients with mildly elevated body lead burden.

REFERRAL

If exposure to lead is work related, it should be reported to the Office of the United States Occupational Safety and Health Administration (OSHA). Follow-up testing is mandatory in all patients after an abnormal screening blood lead level.

PEARLS & CONSIDERATIONS

COMMENTS

- Even blood lead concentrations as low as 5 to 10 mcg/dl are inversely associated with children's IQ scores at age 3 and 5 yr. A recent study evaluating long-term ramifications of childhood lead exposure revealed that childhood lead exposure was associated with lower cognitive function and socioeconomic status at age 38 yr, with declines in IQ, and downward social mobility.[1]
- Screening of household members of affected individuals is recommended.
- In children with blood lead levels of >45 mg/dl, treatment with succimer does not improve scores on tests of cognition, behavior, or neuropsychological function.
- Lead toxicity may delay growth and pubertal development in girls.
- Low-level environmental lead exposure may accelerate progressive renal insufficiency in patients without diabetes who have chronic renal disease. Repeated chelation therapy may improve renal function and slow the progression of renal failure.

TABLE 3 Chelators*

Chelator	Dose	Indications	Contraindications
Deferoxamine	15 mg/kg/hr up to 24 hr (titrate up slowly because of hypotension)	Iron level >500 g/dl or systemic symptoms	
Dimercaprol (British anti-Lewisite [BAL])	Lead encephalopathy: 75 mg/m^2 deep IM injection every 4 hr for 5 days in children or 4 mg/kg every 4 hr for adults Arsenic (severe): No established regimen; consider 3 mg/kg IM every 4 hr for 48 hr; then twice daily for 7-10 days Mercury: 5 mg/kg IM first; then 2.5 mg/kg every 12-24 hr	Lead level >70 g/dl or encephalopathy Arsenic: Symptomatic patient with known exposure Mercury: Inorganic	Peanut allergy Organic mercury poisoning
$CaNa_2EDTA$	1500 mg/m^2/day continuous IV infusion 50 mg/kg/day or 1000 mg/m^2/day in 2-4 divided doses for up to 5 days if less severe symptoms	Lead: Given after first dose of BAL for blood lead level above 70 g/dl or encephalopathy	
Succimer (DMSA)	10 mg/kg q8h × 5 days; then q12h for 14 days	Lead level of 45-69 g/dl Arsenic: If tolerated orally for subacute and chronic toxicity Mercury: Acute and chronic	
D-Penicillamine	25 mg/kg q6h × 5 days	Lead level of 45-69 g/dl, succimer not tolerated Arsenic: Only if BAL and DMSA are unavailable Mercury: If BAL and DMSA are unavailable or not tolerated	Penicillin allergy
DMPS (investigational)	5 mg/kg/dose IM q6-8h day 1, q8-12h day 2, q12-24h day 3 and until 24-hr urine is <50 μg/L	Lead (chronic) Arsenic Mercury	

*Indications for chelation and dosing regimens may change. Consult with a toxicologist or poison control center for the most up-to-date recommendations.
BAL, Dimercaprol; *DMPS*, 2,3-Dimercapto-1-propanesulfonic acid; *DMSA*, dimercaptosuccinic acid; *EDTA*, edetate calcium disodium; *IM*, intramuscular; *IV*, intravenous.
From Marx JA et al: *Rosen's emergency medicine*, ed 8, Philadelphia, 2014, Saunders.

BASIC INFORMATION

DEFINITION

Legg-Calvé-Perthes disease (LCPD) is a childhood condition characterized by disruption of the blood supply to the capital femoral epiphysis, leading to avascular necrosis of the femoral head(Fig. E1). The disease is self-limited; the blood supply to the femoral head recovers spontaneously after progressing through phases of infarction, fragmentation, reossification, and remodeling. The classification of LCPD is outlined in Fig. E2.

SYNONYMS

LCPD
Perthes disease
Coxa plana
Capital femoral osteochondrosis
Osteonecrosis of the proximal femoral epiphysis

ICD-10CM CODE
M91.10 Juvenile osteochondrosis of head of femur [Legg-Calvé-Perthes], unspecified leg

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Four to thirty-two cases per 100,000 children. Varies by country. More common in Caucasians, lower socioeconomic status, less densely populated areas, and people living farther from the equator.
PREDOMINANT SEX: Male:female ratio of 5:1
PREDOMINANT AGE: 4 to 8 yr old

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Initial symptom: A limp that can be painful or painless.
- Pain referred down the anterior hip and medial thigh.
- Positive roll test: With the patient in the supine position, rolling of the affected extremity into internal and external rotation elicits guarding.
- Limited abduction and internal rotation of the hip. Flexion and extension of the hip are usually spared.
- No history of trauma.
- Condition is bilateral in 10% to 20% of patients.

ETIOLOGY

Unknown, but suspected to be multifactorial. Likely a combination of genetic factors that confer susceptibility to vascular compromise and environmental factors (like subclinical trauma) that trigger the disease.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS (TABLE E1)

Unilateral disease:
- Transient synovitis
- Sickle cell disease
- Septic arthritis
- Neoplastic process
- Spondyloepiphyseal dysplasia tarda

Slipped capital femoral epiphysis

BILATERAL DISEASE

- Multiple epiphyseal dysplasia
- Sickle cell disease
- Juvenile idiopathic arthritis

WORKUP

Diagnosis is usually based on physical examination findings and radiographic evaluation.

IMAGING STUDIES

- Plain x-ray (AP and frog-leg lateral views) can be used to diagnose and follow disease progression.
- Contrast-enhanced MRI is the most sensitive for early LCPD.
- Technetium bone scan (Fig. E3) can help confirm the diagnosis in early cases. There is a correlation between size of the uptake defect and prognosis.
- Dynamic pneumoarthrography shows the relationship between the femoral head and the acetabulum, which can aid surgical planning.

TREATMENT

ACUTE GENERAL Rx

- The ultimate goal of treatment is to contain the femoral head inside the acetabulum to protect the vulnerable segment of bone from deforming forces.
- Nonoperative management includes non–weight-bearing status, bracing, range-of-motion exercises, and NSAIDs for pain control.
- Surgical intervention may be required in refractory cases, usually femoral or pelvic osteotomies.

DISPOSITION

- One of the most important prognostic factors is femoral head shape. Excursion of the femoral head is linked to future degenerative arthritis.
- Factors that portend a favorable outcome include younger age of onset, less extensive epiphyseal involvement, and male gender.
- Factors associated with a poor prognosis include obesity, stiffness with progressive loss of hip range of motion, adduction contracture, and a longer duration of disease.

REFERRAL

Refer to a pediatric orthopedist when the diagnosis is suspected

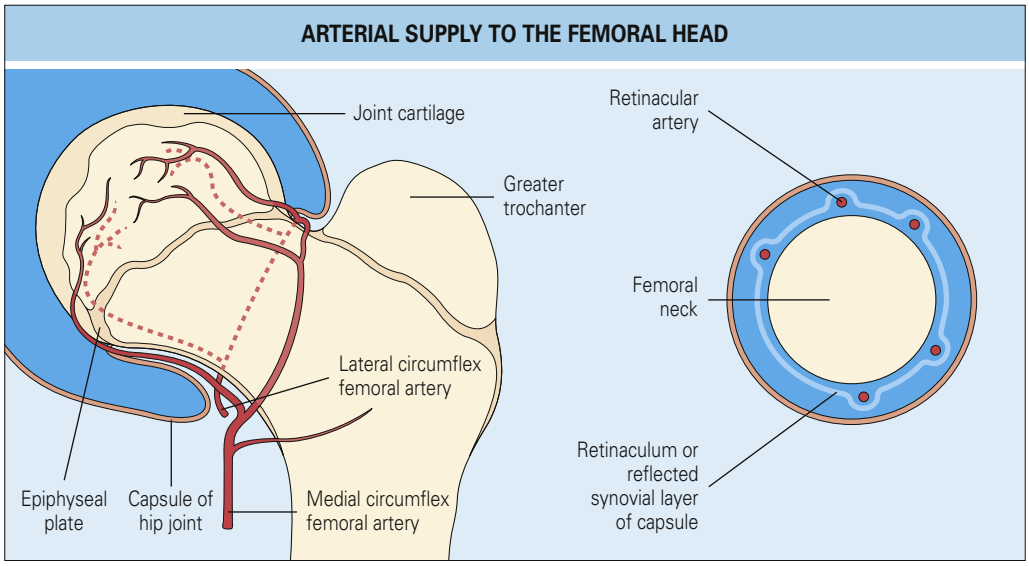

FIG. E1 Normal blood supply to the femoral head in a 4-yr-old child. A blockage of this blood supply, which is yet not fully understood, leads to Legg-Calvé-Perthes disease. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

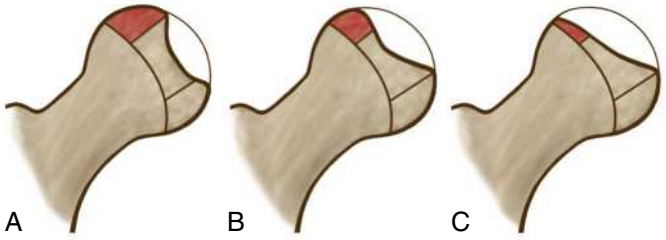

FIG. E2 Lateral pillar classification for Legg-Calvé-Perthes disease. A, There is no involvement of the lateral pillar. **B,** More than 50% of the lateral pillar height is maintained. **C,** Less than 50% of the lateral pillar height is maintained. (From Kliegman, RM: *Nelson Textbook of Pediatrics*, ed 21, Philadelphia, 2020, Elsevier.)

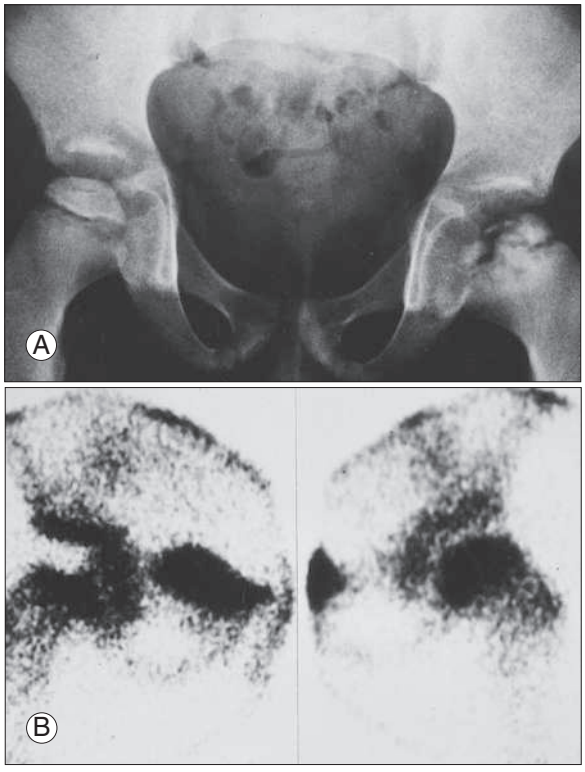

FIG. E3 Pelvic radiograph and technetium bone scintiscan for an 8-yr-old with Legg-Calvé-Perthes (LCP) disease. (A) The child has early involvement of the right hip, with relatively subtle changes apparent on the radiograph. **(B)** The bone scintiscan, however, shows complete blood loss in the right femoral head, consistent with osteonecrosis. The left hip shows classic, more advanced stages of LCP disease (in the revascularization phase), with return of normal blood flow visible on the scintiscan. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

TABLE E1 Differential Diagnosis of Legg-Calvé-Perthes Disease

Other Causes of Avascular Necrosis

- Sickle cell disease
- Other hemoglobinopathies (e.g., thalassemia)
- Chronic myelogenous leukemia
- Steroid medication
- Sequela of traumatic hip dislocation
- Treatment of developmental dysplasia of the hip
- Septic arthritis

Epiphyseal Dysplasias

- Multiple epiphyseal dysplasia
- Spondyloepiphyseal dysplasia
- Mucopolysaccharidoses
- Hypothyroidism

Other Syndromes

- Osteochondromatosis
- Metachondromatosis
- Schwartz-Jampel syndrome
- Trichorhinophalangeal syndrome
- Maroteaux-Lamy syndrome
- Martsolf syndrome

From Kim HKW, Herring JA: Legg-Calvé-Perthes disease. In Herring JA, editor: *Tachdjian's pediatric orthopaedics*, ed 5. Philadelphia, 2014, WB Saunders, Box 17.6, p. 613. In Kliegman, RM: *Nelson Textbook of Pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

PEARLS & CONSIDERATIONS

LCPD is an idiopathic, self-limited condition characterized by avascular necrosis of the skeletally immature femoral head. The etiology of LCPD remains controversial. Treatment recommendations vary widely and continue to evolve. A subset of patients will require surgical intervention; therefore, prompt referral to a pediatric orthopedist is warranted.

Legionnaires Disease

BASIC INFORMATION

DEFINITION

Pneumonia caused by *Legionella pneumophila*

SYNONYM

Legionella pneumonia

ICD-10CM CODE

A48.1 Legionnaires' disease

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE: Rough estimates of 18 to 36 cases per 100,000, mostly sporadic cases, occasional community outbreaks due to contaminated fresh water sources. Nosocomial outbreaks have been reported.
PREDOMINANT SEX AND AGE: Male gender with twofold increased risk, age >50
RISK FACTORS: Chronic heart disease, smoking, end-stage renal disease, immunosuppression, cancer. No person-to-person transmission

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute respiratory illness similar to other forms of community-acquired pneumonia.
- Hypoxia, cough, physical exam with localizing chest findings.
- A febrile prodrome with myalgia, anorexia, and headaches can occur, which may be confused with influenza.
- Gastrointestinal symptoms such as diarrhea and abdominal pain are common.

ETIOLOGY

Legionella pneumophila, atypical agent. Grows in warm water sources and can cause outbreaks

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Clinically indistinguishable from other typical and atypical pneumonias

WORKUP

Similar to other pneumonias. CURB 65 or PSI may be used to stratify patients according to severity.

LABORATORY TESTS

- Legionella urinary antigen highly sensitive for Legionella serotype 1 (80% of Legionella strains).
- Additional lab abnormalities such as liver function tests, hyponatremia, elevated creatine kinase, coagulopathy are commonly seen.

IMAGING STUDIES

CXR (Fig. E1) with focal or diffuse consolidation, indistinguishable from other pneumonias

TREATMENT

NONPHARMACOLOGIC THERAPY

Supportive therapy: Oxygen, may require intubation for severe hypoxia, fluid management in case of diarrhea

ACUTE GENERAL Rx

- Antibiotic coverage for atypical pneumonia. Azithromycin or levofloxacin are recommended. Treatment duration similar to other forms of community-acquired pneumonia, with the exception of severely immunosuppressed patients who are treated for up to 21 days.
- Table 1 summarizes preferred therapy for Legionnaire disease.

DISPOSITION

- Mild cases managed as outpatient are likely under-diagnosed due to lack of specific testing.
- Recognized as cause of severe pneumonia with high rates of ICU admission.

REFERRAL

- Pulmonologist/infectious disease specialist in severe cases.
- Identified cases should be reported to public health authorities for prompt recognition of outbreaks.

PEARLS & CONSIDERATIONS

COMMENTS

Pontiac fever is an acute systemic illness caused by Legionella without specific pneumonia features. Local outbreaks have been reported.

PREVENTION

Prompt recognition of clusters to identify water source is pivotal to contain an outbreak.

PATIENT & FAMILY EDUCATION

To be recognized as potential public health problem. No risk for transmission to other family members.

Pneumonia, Bacterial (Related Key Topic)

AUTHOR: **Sebastian G. Kurz, MD**

TABLE 1 Preferred Therapy for Legionnaires Disease

Clinical Condition	First Choices	Dosage*,†	Second Choices	Dosage*,†
Mild pneumonia inpatient or outpatient, not immunocompromised	Azithromycin *or*	500 mg 1×/day for 3-5 days	Doxycycline	200 mg load, then 100 mg 2×/day for 10-14 days
	Levofloxacin *or*	500 mg 1×/day for 7-10 days	Erythromycin	500 mg 4×/day for 10-14 days
	Ciprofloxacin *or*	500 mg 2×/days for 7-10 days		
	Moxifloxacin *or*	400 mg 1×/day for 7-10 days		
	Clarithromycin	500 mg 2×/day for 10-14 days		
Moderate to severe pneumonia or immunocompromised‡	Azithromycin *or*	500 mg 1×/day for 5-7 days	Ciprofloxacin *or*	750 mg 2×/day for 14 days
			Moxifloxacin *or*	400 mg 1×/day for 14 days
	Levofloxacin	500 mg 1×/day for 7-10 days 750 mg 1×/day for 5-7 days	Erythromycin *or*	750-1000 mg IV 4×/day for 3-7 days, then 500 mg 4×/day for a total course of 21 days
			Clarithromycin	500 mg IV 2×/day for 3-7 days, and then 500 mg 2×/day for a total course of 21 days

*Dosage adjustments have to be made for renal insufficiency for some of these drugs. Patients with mild disease may be treated entirely with oral therapy, whereas for severely ill patients parenteral therapy is advised until improvement is seen and oral absorption is sufficient.
†Therapy duration may need to be considerably longer for patients with lung abscesses, empyema, endocarditis, or extrathoracic infection.
‡Severely immunocompromised patients may require courses of therapy at the high end of the duration ranges given, or even longer. Close clinical follow-up is required to detect possible relapse after antibiotics have been discontinued.

BASIC INFORMATION

DEFINITION

Leishmaniasis is a vector-borne infectious disease caused by a heterogeneous group of obligate intracellular protozoan parasites belonging to the genus *Leishmania* and resulting in a variety of different clinical syndromes. Leishmaniasis parasites mostly are transmitted to humans through sand fly bites.

SYNONYMS

Kala-azar
Old World leishmaniasis
New World leishmaniasis

ICD-10CM CODES

B55.9	Leishmaniasis, unspecified
B55.0	Visceral leishmaniasis
B55.1	Cutaneous leishmaniasis
B55.2	Mucocutaneous leishmaniasis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: ~2 million total new cases and 500,000 visceral cases occur each yr with almost 400 million people at risk for the disease. It is endemic in nearly 100 countries.

- Can be classified geographically into New World versus Old World disease (Fig. E1).
- Infection can be divided into cutaneous, mucocutaneous, visceral disease.
- Different *Leishmania* species are associated with different patterns of disease.
- Incubation period: From 1 wk to many mo for cutaneous and mucosal leishmaniasis; 2 to 6 mo (range is 10 days to yrs) for visceral leishmaniasis.
- Mode of transmission: By the female sand fly vector (mainly of the genera *Phlebotomus* in the Old World and *Lutzomyia* in the New World) in the majority of cases, but it also can be spread via shared needles, blood transfusions, organ transplants, vertically from the mother to fetus, or sexually.
- The reservoir for the parasite consists of canines, rodents, and humans.
- Cutaneous leishmaniasis had been reported in U.S. military personnel in Iraq (more than 2000 cases from 2001 to 2015).
- Travelers to endemic areas have become infected after <1 wk of exposure.
- Untreated visceral leishmaniasis is almost always fatal.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Cutaneous syndrome:

- Localized cutaneous leishmaniasis: Usually presents as an ulcerative skin lesion at the site of the sand fly bite (Fig. E2), which resolves within several wk or mo, often leaving a residual scar
- Mucosal leishmaniasis–usually caused by *L. braziliensis;* also known as "espundia"
- Leishmaniasis recidivans
- Diffuse cutaneous leishmaniasis visceral syndrome
- Viscerotrophic leishmaniasis: Fever, chronic fatigue, malaise, cough, intermittent diarrhea, and abdominal pain. Signs include adenopathy, hepatosplenomegaly, hyperpigmentation of skin, petechiae, jaundice, edema, and ascites
- Post–kala-azar dermal leishmaniasis: Generalized cutaneous rash that is often papular or nodular; severe forms with desquamation of skin and mucosa

ETIOLOGY

- Old World parasite: *Leishmania tropica, L. major, L. aethiopica, L. donovani, L. infantum.*
- New World parasite: *L. braziliensis and L. mexicana complex, L. chagasi, L. b. guyanensis, L. b. panamensis.*
- *L. chagasi* has recently been found to be identical to *L. infantum.*
- More than 20 distinct species of *Leishmania* have been described.
- After the host has been inoculated by the bite of the sand fly, the parasites in promastigote stage are phagocytized by macrophages in the dermis and transform into amastigotes,

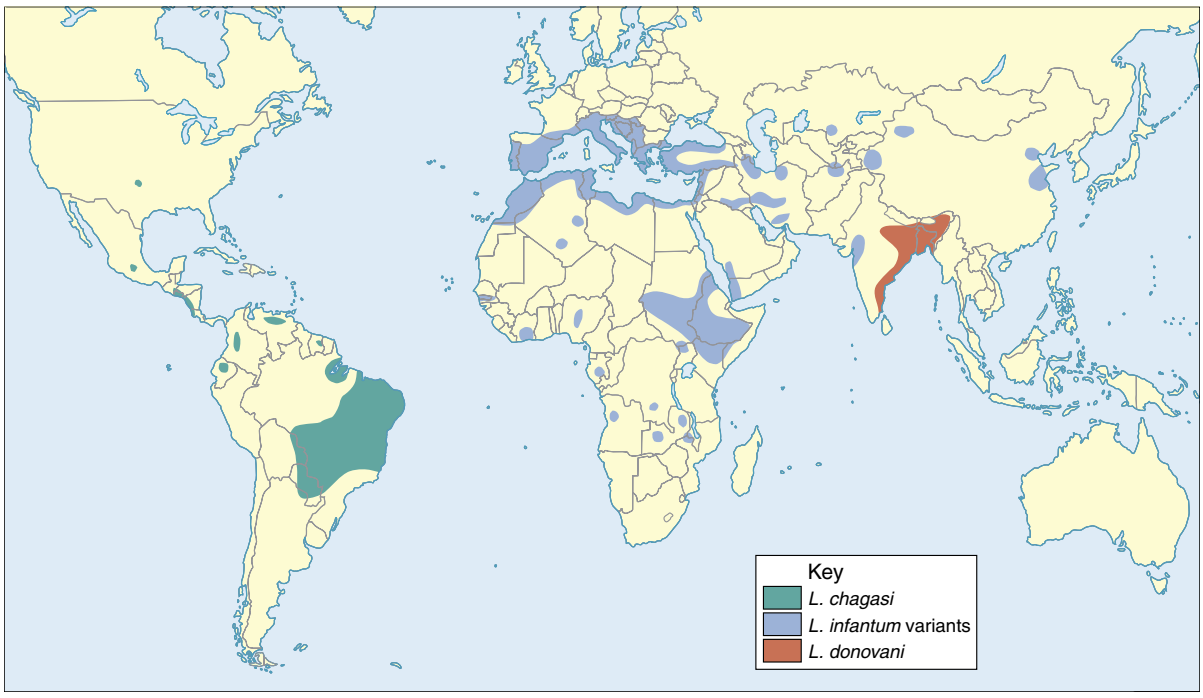

FIG. E1 Epidemiology of visceral leishmaniases (VL). VL caused by parasites of the *Leishmania donovani–Leishmania infantum* complex occurs in the Mediterranean littorals, the Middle East, adjacent parts of the former Soviet Union, the Sudan, East Africa, the Indian subcontinent, China, and South America *(Leishmania chagasi).* An arid, warm environment provides ideal ecologic conditions for the breeding of many species of sand fly. Zoonotic kala-azar due to *L. infantum* and *L. chagasi* is commonly associated with dry, rocky hill country, where cases typically are scattered. In India, *L. donovani* is essentially an anthroponosis. This type of kala-azar may occur in severe epidemic fashion, as can kala-azar in the Sudan. (From Hoffman R: *Hematology, basic principles and practice*, ed 6, Philadelphia, 2013, Saunders.)

FIG. E2 Cutaneous leishmaniasis. An erythematous, crusted plaque in a 4-yr-old child. (Courtesy William Burrows, M.D. In Paller AS, Mancini, AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

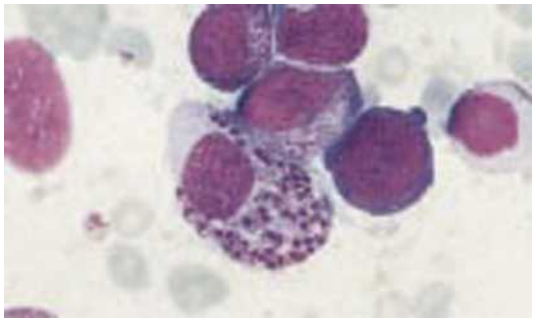

FIG. E3 *Leishmania infantum* in macrophage from bone marrow. Although typically found in macrophages as shown here, isolated extracellular amastigotes from disrupted host cells are commonly seen in such preparations. (From Hoffman R: *Hematology, basic principles and practice*, ed 6, Philadelphia, 2013, Saunders.)

which replicate by simple binary division, rupture the cell and invade other reticuloendothelial cells.

DX DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Malaria
- African trypanosomiasis
- Brucellosis
- Enteric fever
- Bacterial endocarditis
- Generalized histoplasmosis
- Chronic myelocytic leukemia
- Hodgkin disease and other lymphomas
- Sarcoidosis
- Hepatic cirrhosis
- Tuberculosis

WORKUP

- Full thickness punch biopsy of a skin lesion
- On biopsy specimen can perform culture and histology
- PCR: SMART Leish PCR, RT-PCR
- Bone marrow bx for visceral disease
- Splenic aspirate often done in resource-poor settings

LABORATORY TESTS

- CBC: Anemia, neutropenia, thrombocytopenia, and eosinopenia
- LFTs: Hypergammaglobulinemia, hypoalbuminemia, and hyperbilirubinemia
- Elevated BUN and creatinine
- Specific diagnosis confirmed by intracellular amastigote (Fig. E3) in Giemsa-stained impression smears or sectioned tissue or culture performed in NMN (Novy, MacNeal, Nicolle) or Schneider drosophila medium
- Serologic diagnosis: ELISA, direct agglutination tests, and K39 ELISA are limited by the fact they cannot detect past from present infection, and there may be cross-reaction between visceral and cutaneous leishmaniasis.
  1. Serology is not effective for diagnosis of cutaneous leishmaniasis.
- Montenegro skin test: Not in use in the U.S.
- PCR is one of the most sensitive diagnostic tests for cutaneous leishmaniasis. Examples include SMART Leish PCR and RT-PCR. These tests are also excellent for species detection.

RX TREATMENT

NONSPECIFIC OR SUPPORTIVE CARE

- Nutritional diet
- Antimicrobial agents for concurrent infections
- Blood transfusions
- Iron and vitamins

SPECIFIC ANTILEISHMANIAL THERAPY:

Visceral leishmaniasis

- Liposomal amphotericin B (AmBisome) in various regimens is the preferred drug for visceral leishmaniasis
- Pentavalent antimonials: Sodium stibogluconate (Pentostam) IV/IM and meglumine antimoniate IV/IM (Glucantime) may be used, but they can have significant cardiotoxicity and cause a clinical pancreatitis, and in some geographic areas (e.g., in Asia, northern India, and Nepal) a resistance has emerged.
- Miltefosine (2.5 mg/kg/day orally in two divided doses for 28 days, but patient must weigh at least 30 kg) is an effective oral choice for cutaneous, mucosal, and visceral disease. Teratogenic in animals, so cannot be used in pregnancy.

Extraintestinal leishmaniasis

- Pentavalent antimony or liposomal amphotericin B
- Miltefosine

Cutaneous leishmaniasis (mild disease)

- Paromomycin ointment BID × 10 days, rest 10 days, then 10 more days
- Paromomycin cream (15%)
- Cryotherapy with liquid nitrogen or laser therapy
- Intralesional antimony with Pentostam or Glucantime

Cutaneous leishmaniasis (moderate disease)

- Miltefosine
- Sodium stibogluconate (Pentostam)
- Meglumine antimonate (Glucantime)
- Fluconazole 200 mg PO qd × 6 wk
- Ketoconazole 600 mg PO qd × 30 days
- Amphotericin B

DISPOSITION

Follow-up examination is important for early detection and treatment relapse.

REFERRAL

To infectious disease experts for accurate diagnosis and management

PEARLS & CONSIDERATIONS

COMMENTS

- Prevention by reservoir control: Destruction of animal reservoir hosts, mass treatment of humans in kala-azar–prevalent areas.
- Prevention by vector control: Includes use of bed nets and screens, insecticide spraying in domestic and peridomestic areas.
- Vaccines are in various stages of development and clinical trials. None are licensed or commercially available at this time.
- Co-infection with HIV can lead to more severe disease and/or atypical presentations and requires more intense therapy as well as antiretroviral therapy.

BASIC INFORMATION

DEFINITION

Lemierre syndrome refers to a jugular vein suppurative thrombophlebitis preceded by a pharyngitis and is often associated with a bacteremia with organisms of the oral flora and subsequent septic emboli. The most common pathogen is *Fusobacterium necrophorum*.

SYNONYMS

Postanginal sepsis
Necrobacillosis

ICD-10CM CODE
I80.8 Phlebitis and thrombophlebitis of other sites

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 0.6 to 3.6 cases per million overall but increases to 14.4 cases per million in ages 15 to 24 yr, and cases seem to be increasing.
PEAK INCIDENCE: In one study of 114 patients with Lemierre syndrome, the median age was 22 yr.
RISK FACTORS: Cases appear to be more common in the 15 to 24 yr age group due to involution of tonsillar tissue predisposing this age group to infections in tonsillar crypts.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- A diagnosis of Lemierre syndrome can be made with the following criteria:
  1. Recent pharyngeal infection followed 4 to 5 days later by high fever
  2. Complication of septic emboli: Lung (most frequent: Over 90%), joint, muscle
  3. Thrombosis of the internal jugular vein or findings of positive blood cultures with *F. necrophorum*
- Pharyngeal infection can be tonsillitis, pharyngitis, or common sore throat. Rarer presentations include neck swelling, odontogenic infections, central nervous system (CNS) infections.

ETIOLOGY

The infection begins as a localized oropharyngeal infection, which then spreads to involve the lateral pharyngeal space and then the structures of the carotid sheath, eventually causing an ipsilateral septic thrombophlebitis of the internal jugular vein and then septic emboli from the thrombus (Fig. E1).

MICROBIOLOGY

- Fusobacterium: *Fusobacterium necrophorum* is the most common isolated organism and is an anaerobic gram-negative rod that is part of the oral flora and causes up to 10% of cases of throat infection. Its detection in blood culture should prompt consideration of this syndrome. Other possible Fusobacteria include *F. nucleatum*
- Streptococcus: Includes *Streptococcus pyogenes*
- Others: *Eikenella corrodens, Porphyromonas asaccharolytica*

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Viral pharyngitis
- Epstein-Barr virus
- Group A Streptococcal pharyngitis
- Peritonsillar abscess
- Retropharyngeal abscess

WORKUP

Consists of a clinical suspicion of a patient worsening after a pharyngitis, cultures, and appropriate imaging studies

LABORATORY TESTS

- Complete blood count with differential
- Blood cultures, as patients usually have high fever; Fusobacteria may take 2 to 7 days to grow
- C-reactive protein

IMAGING STUDIES

- High-resolution CT scans with contrast are best to detect the thrombophlebitis of the internal jugular vein and by extension the septic emboli to the lung.
- Ultrasound and MRI can also be used to demonstrate the thrombus in internal jugular vein.

TREATMENT

Antibiotics are the mainstay of treatment, with anticoagulation still a controversial issue.

ACUTE GENERAL Rx

- Fusobacteria can be resistant to penicillin and may produce beta-lactamase enzymes.
- Beta-lactamase resistant beta-lactam antibiotics are considered antibiotics of choice:
  1. Ampicillin-sulbactam: 3 g IV q6h for adults
  2. Piperacillin-tazobactam: 4.5 g IV q6h for adults
- Other effective antibiotics: Carbapenems antibiotics: Meropenem or imipenem.
- Metronidazole offers excellent coverage for *Fusobacterium* but not *Streptococci*.
- Length of therapy in studies ranges from 10 days to 8 wk. Mean duration is 4 wk.
- Anticoagulation is controversial but has been used only with evidence of extension of the clot.

DISPOSITION

Surgery: Accessible abscesses should be drained. Ligation of the affected vein is rarely needed.

PEARLS & CONSIDERATIONS

COMMENTS

- *Fusobacterium necrophorum* produces hemagglutinin, which promotes platelet aggregation that could then yield to thrombus formation.
- Lemierre syndrome is also known as the "forgotten disease" because the antibiotic era dramatically reduced cases, but cases may be rising again due to emphasis on avoiding excess antibiotics.
- Mortality rate is approximately 2%.

RELATED TOPICS

Pharyngitis/Tonsillitis (Related Key Topic)

AUTHOR: **Glenn G. Fort, MD, MPH**

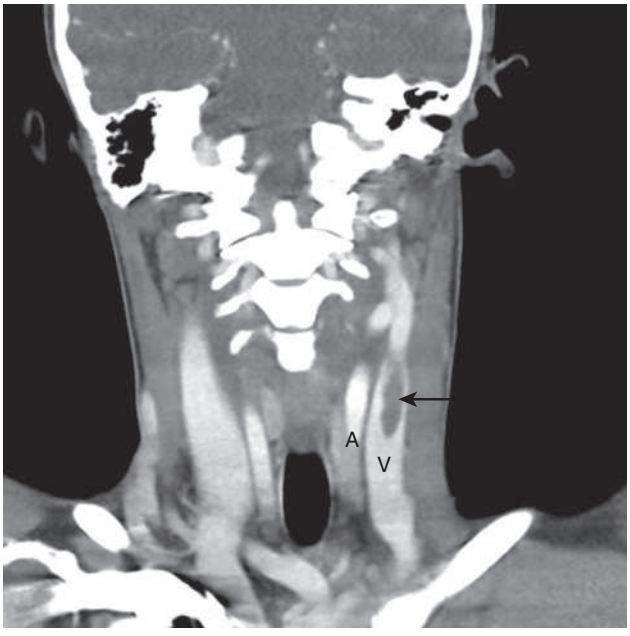

FIG. E1 Coronal computed tomography of the neck with contrast reveals a soft tissue attenuation filling defect in the left internal jugular vein (*black arrow*). BASIC INFORMATION

DEFINITION

Leprosy is a chronic granulomatous infectious disease of humans that primarily affects the skin and peripheral nerves.

SYNONYM

Hansen disease

ICD-10CM CODES

A30.0	Indeterminate leprosy
A30.1	Tuberculoid leprosy
A30.2	Borderline tuberculoid leprosy
A30.3	Borderline leprosy
A30.4	Borderline lepromatous leprosy
A30.5	Lepromatous leprosy
A30.8	Other forms of leprosy
A30.9	Leprosy, unspecified
B92	Sequelae of leprosy

EPIDEMIOLOGY & DEMOGRAPHICS

- The number of cases worldwide has fallen from >5.4 million cases in 1985 to about 211,000 cases in 2017 in 154 different countries, according to the World Health Organization (WHO).
- Nearly 75% of the cases of leprosy are found in India, Brazil, Nepal, Mozambique, Madagascar, and Myanmar (see Fig. E1).
- More than 85% of the cases diagnosed in the United States are found among immigrants.
- Annual incidence in the United States is between 50 and 100 new cases per yr (Fig. E2). In 2014 there were 175 new cases in the U.S., 75% of them from 7 states: Arkansas, California, Florida, Hawaii, Louisiana, New York, and Texas.
- Leprosy is more common in men than women (2:1).
- Leprosy can occur at any age but usually is found in young children.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- A skin lesion: Most common initial presentation
- Sensory loss
- Anhidrosis
- Neuritic pain
- Palpable peripheral nerves
- Nerve damage (most commonly affected nerves are ulnar, median, common peroneal, posterior tibial, radial cutaneous nerve of the wrist, facial, and posterior auricular)
- Muscle atrophy and weakness
- Foot drop
- Claw hand and claw toes
- Lagophthalmos, nasal septal perforation, collapse of bridge of nose, loss of eyebrows resulting in "leonine" facies
- Leprosy can present along a spectrum from simple cutaneous skin lesions (Fig. E3, Fig. E4) with minimal sensory loss to severe extensive skin involvement (Fig. E5), painful neuritis, muscle wasting and contractures, and multiple peripheral nerve damage. Erythema nodosum leprosum (ENL) occurs in half of patients with borderline lepromatous or lepromatous leprosy, 90% of the time within yrs of institution of antibiotic treatment for Hansen disease or during pregnancy. ENL is a circulating immune complex–mediated disease. Skin lesions are erythematous, subcutaneous, and dermal nodules that are

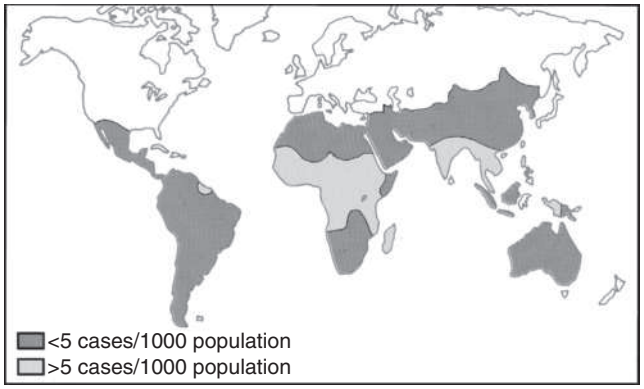

FIG. E1 Geographic distribution of leprosy. (From Souhami RL, Moxham J: *Textbook of medicine,* ed 4, London, 2002, Churchill Livingstone.)

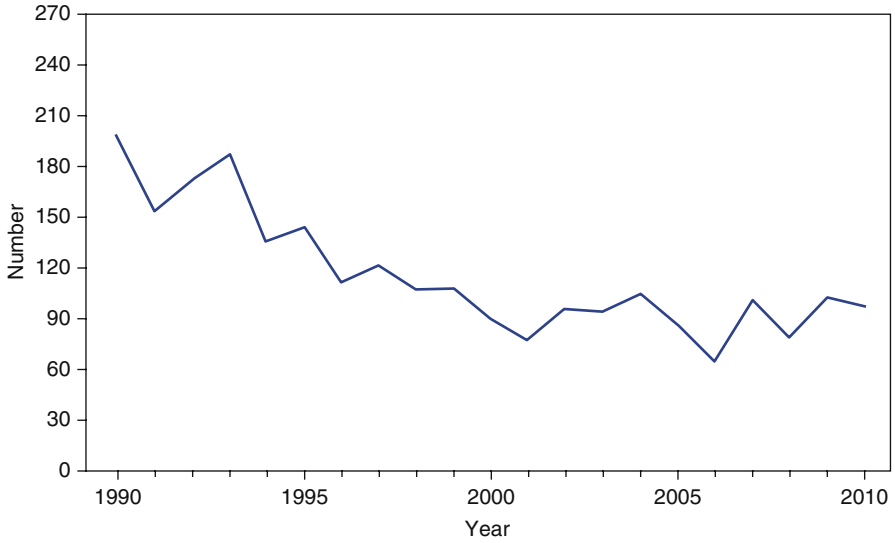

FIG. E2 Hansen disease (leprosy). Number of reported cases by yr—United States, 1990-2010. (From Centers for Disease Control and Prevention: Summary of notifiable diseases—United States, 2010, *MMWR Morb Mortal Wkly Rep* 59:1-111, 2012.)

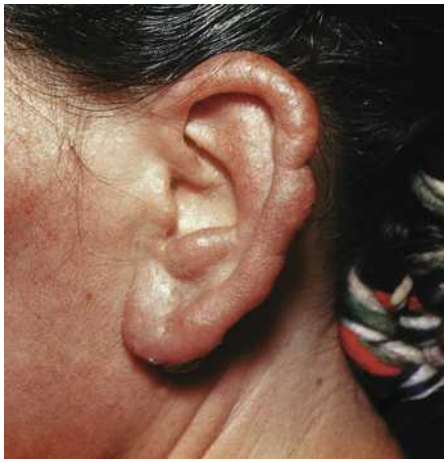

FIG. E3 Lepromatous leprosy, ear involvement. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

FIG. E4 Histoid leprosy. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

FIG. E5 Type 1 reaction in Hansen disease. (Courtesy Curt Samlaska, MD, from James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

FIG. E6 Erythema nodosum leprosum. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

widely distributed (Fig. E6). They do not occur at sites of existing skin lesions
- Lucio phenomenon is an uncommon and unusual reaction that occurs in patients with diffuse lepromatous leprosy (DLL) of the "la bonita" type, most often found in western Mexico, and is often the reason for the initial presentation in affected patients. Purpuric macules evolve to bullous lesions that rapidly ulcerate, especially below the knees (Fig. E7)

ETIOLOGY

- Leprosy is caused by *Mycobacterium leprae,* an obligate intracellular acid-fast rod.
- The mode of transmission is thought to be through nasal secretions. Spread in humans is thought to occur via the respiratory route or entry through broken skin in patients with multibacillary disease or extensive paucibacillary disease.

FIG. E7 Lucio phenomenon, early bullous lesions. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

- Zoonotic transmission from armadillos has been shown in a few case reports. More common in the southern region of the United States such as Louisiana and Texas.
- The majority of people exposed to patients with leprosy do not develop the disease because of their natural immunity. Variants of genes in the *NOD2*-mediated signaling pathway (which regulates the innate immune response) are associated with susceptibility to infection with *M. leprae.*

Dx DIAGNOSIS

- The diagnosis of leprosy (Table E1) relies on a detailed history and physical examination and is established by the demonstration of acid-fast bacilli in skin smears or skin biopsies of the affected sites.
- Leprosy has been classified according to the WHO system into:
  1. Paucibacillary leprosy is defined as <5 skin lesions with no bacilli on skin smear.
  2. Multibacillary leprosy is defined as >5 skin lesions and may be skin-smear positive. This system of classification is designed for ease of use by paraprofessionals.
- Hansen disease may present with a broad spectrum of clinical disease. The Ridley-Jopling system classifies cases based on clinical, bacteriologic, immunologic, and histopathologic features (Table E2) as follows:
  1. Indeterminate leprosy
  2. Tuberculoid leprosy (paucibacillary [few organisms], intense inflammatory reaction (Fig. E8); few, well-demarcated skin lesions)

TABLE E1 Criteria for Classification of Leprosy

Group	Clinical Features	Histologic Features	Lepromin Reaction (Mitsuda)	Bacillary Density
Tuberculoid	• Single or few anesthetic macules or plaques • Borders well defined • Peripheral nerve involvement common	• Epithelioid-lymphocyte granulomas, with or without giant cells, in skin and nerves • No subepidermal clear zone • Bacilli in nerves, but rare	Strongly positive	Rare
Borderline tuberculoid	• Lesions similar to those of tuberculoid, but more numerous • Borders of lesions less distinct • Satellite lesions sometimes present around larger lesions • Peripheral nerve involvement common	• Granulomas similar to those in tuberculoid • Nerves are infiltrated • Bacilli frequently found in nerves	Positive	Scanty
Borderline	• More lesions than in borderline tuberculoid • Borders more vague • Satellite lesions often seen • Peripheral nerve involvement common	• Epithelioid cells and histiocytic infiltrations focalized by lymphocytes • Nerves show increased cellularity • Bacilli readily found in nerves	Negative or weakly positive	Moderate
Borderline lepromatous	• Lesions are numerous and similar to those of borderline • Some nerve damage	• Histiocytic infiltrations show a tendency to evolve toward epithelioid cells and foamy cells • Lymphocytes present • Nerves have less cellular infiltration • Bacilli plentiful in nerves	Negative	Heavy
Lepromatous	• Multiple, nonanesthetic, macular or papular, symmetrically distributed lesions • No neural lesions until late • Late complications of madarosis, leonine facies, testicular damage	• Foamy histiocytes containing large numbers of bacilli • Few or no lymphocytes • Subepidermal clear zone • Numerous bacilli in nerves and perineurium without significant intraneural cellular infiltration	Negative	Very heavy
Indeterminate	Vaguely defined hypopigmented or erythematous macule	• Often indistinguishable from mild nonspecific dermatitis • Lymphocytes and histiocytes around skin appendages and nerves	Weakly positive or negative	Negative or scanty

From Cherry JD et al.: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

TABLE E2 Spectrum of Host-Parasite Relationship in Hansen Disease

1. Indeterminate leprosy
2. Tuberculoid leprosy (paucibacillary [few organisms], intense inflammatory reaction (Fig. E8); few, well-demarcated skin lesions)
3. Borderline tuberculoid leprosy (Fig. E9)
4. Borderline lepromatous leprosy (Fig. E10)
5. Lepromatous leprosy (multibacillary [numerous organisms], inadequate host response; diffuse, poorly organized skin lesions [Fig. E11])
6. This system of classification is more accurate and is used by physicians

Modified from Dr. J. H. Petit, from James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.

FIG. E8 Tuberculoid leprosy. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

3. Borderline tuberculoid leprosy (Fig. E9)
4. Borderline lepromatous leprosy (Fig. E10)
5. Lepromatous leprosy (multibacillary [numerous organisms], inadequate host response; diffuse, poorly organized skin lesions [Fig. E11])
6. This system of classification is more accurate and used by physicians

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of leprosy includes sarcoidosis, rheumatoid arthritis, systemic lupus erythematosus, lymphomatoid granulomatosis, carpal tunnel syndrome, cutaneous leishmaniasis, fungal infections and other causes of hypopigmented, hyperpigmented, and erythematous skin lesions.

WORKUP

Any patient who presents with skin lesions and a sensory or muscle deficit should have a workup for leprosy.

FIG. E9 Borderline tuberculoid leprosy. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

FIG. E10 Borderline lepromatous leprosy. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

LABORATORY TESTS

- *Mycobacterium leprae* cannot be cultured on artificial media. The bacteria proliferate when injected into the footpads of mice or armadillos and can be used for drug-sensitivity testing.
- Serologic tests, including the antibody to phenolic glycolipid 1 (PGL-1) and bacilli detection in tissue using PCR, are available and used for diagnostic confirmation and research epidemiologic studies.
- Lepromin intradermal skin test is not diagnostic and not for commercial use.
- Skin biopsies of active sites are stained for acid-fast bacilli.
- Peripheral nerve biopsy can be done in patients with sensory loss and no skin lesions. Common nerves biopsied are the radial cutaneous nerve of the wrist and the sural nerve of the ankle.

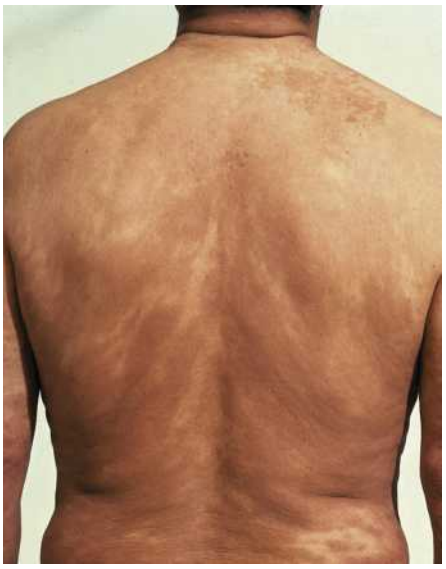

FIG. E11 Lepromatous leprosy. (From James WD et al: *Andrews' diseases of the skin,* ed 12, Philadelphia, 2016, Elsevier.)

IMAGING STUDIES

Radiograph studies are usually of no benefit in the diagnosis or treatment of leprosy.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Physical therapy for patients with upper and lower extremity deformities.
- Proper foot care and footwear to prevent ulcer formation.

ACUTE GENERAL Rx (TABLE E3)

CURRENT STANDARD U.S. REGIMENS (FOR ADULTS): For paucibacillary leprosy:

- Dapsone 100 mg PO q day plus rifampin 600 mg PO q day for 6 mo (World Health Organization regimen). The National Hansen's Disease Program (NHDP) recommends dapsone 100 mg/day plus rifampin 600 mg/day PO for 12 mo.
- For multibacillary leprosy:
- Dapsone 100 mg PO q day plus clofazimine 50 mg/day plus rifampin 600 mg PO q day for 2 yr, (NHPD; WHO recommends 1 yr of therapy).
- An alternative regimen consists of dapsone 100 mg/day plus rifampin 600 mg/day plus minocycline 100 mg/day for 24 mo if clofazimine is refused or unavailable.

CHRONIC Rx

- If relapse occurs, the patient is treated with the same medical regimen; drug resistance is low.
- If relapse is from paucibacillary to multibacillary, the medical regimen for multibacillary should be used for therapy.

DISPOSITION

- Relapse is <1% for multibacillary and just over 1% in paucibacillary cases.
- Patients are initially followed up monthly and, when treatment is completed, every 3 to 6 mo for the next 5 to 10 yr.
- Some patients develop reactions known as erythema nodosum leprosum and reversal reaction, usually during treatment.
  1. Erythema nodosum leprosum results in tender nodules and is treated with thalidomide 100 mg qid, then tapered with response. Cases not responsive to thalidomide are treated with prednisone 60 to 80 mg qday.
  2. Reactive reaction results in the development of new skin lesions with swelling and erythema of existing lesions. Treatment is with prednisone 60 to 80 mg a day then a taper dose. Clofazimine and dapsone are options. Do not use thalidomide.
  3. Other agents used in the treatment of leprosy include ofloxacin, moxifloxacin, minocycline, and clarithromycin.

REFERRAL

- National Hansen's Disease Programs (NHDP) Center in Baton Rouge, Louisiana, and 15 outpatient clinics in the United States offer consultations and treatment. Telephone: 1-800-642-2477.
- Directly observed therapy (DOT), much like DOT for tuberculosis, is highly desirable and should be used if feasible, at least in the first 6 to 12 mo of therapy.
- Any suspected case of leprosy merits an infectious disease consultation. Consultation with orthopedics, podiatry, ophthalmology, physical therapy, plastic surgery, and psychology are all in order for any of the potential sequelae of the disease.

PEARLS & CONSIDERATIONS

COMMENTS

- The risk of transmission is low in patients with leprosy, and therefore no infection control precautions of hospitalized patients are needed.
- Family members and close contacts need to be examined frequently for the development of lesions.
- Dapsone or rifampin prophylaxis is not recommended in the prevention of leprosy.
- BCG vaccination has a 50% efficacy in the prevention of leprosy and may be considered.

Leprosy (Patient Information)

AUTHOR: **Glenn G. Fort, MD, MPH**

TABLE E3 Suggested Dosing Regimens for Leprosy from the World Health Organization[1,2] and National Hansen's Disease Program[3]

Leprosy Classification	Drug	DOSE[d]			Duration
		Age <10 yr	Age 10-14 yr	Age ≥15 yr	
Paucibacillary[a]	Dapsone	1-2 mg/kg/day	1-2 mg/kg/day	100 mg daily	WHO: 6 mo NHDP: 12 mo
	Rifampin	10-20 mg/kg/day	10-20 mg/kg/day	600 mg daily (NHDP) 600 mg monthly (WHO)	
Multibacillary[b]	Dapsone	1-2 mg/kg/day	1-2 mg/kg/day	100 mg daily	WHO: 12 mo NHDP: 24 mo
	Rifampin	10 mg/kg/day	10 mg/kg/day	600 mg monthly (WHO) 600 mg daily (NHDP)	
	Clofazimine[c]	50 mg biweekly + 100 mg monthly (WHO) 1 mg/kg/day (NHDP)	50 mg every other day + 150 mg monthly (WHO) 1 mg/kg/day (NHDP)	50 mg daily (NHDP, WHO) ± 300 mg load monthly (WHO)	
	Minocycline (second line for dapsone or clofazimine)	25 mg monthly if <15 kg; 50 mg monthly if 15-30 kg (WHO) ND (NHDP)	50 mg monthly (WHO) ND (NHDP)	100 mg monthly (WHO) 100 mg daily (NHDP)	Extend multidrug therapy to 2 yr[4]
	Ethionamide (second line for clofazimine)	50-75 mg daily if <15 kg, 150-175 mg daily if 15-30 kg (WHO) ND (NHDP)	275-375 mg daily (WHO) ND (NHDP)	275-375 mg daily	
	Ofloxacin (second line for clofazimine or rifampin)	100 mg monthly if <15 kg, 200 mg monthly if 15-30 kg (WHO) Not recommended (NHDP)	200 mg monthly (WHO) Not recommended (NHDP)	400 mg monthly (WHO) 400 mg daily (NHDP)	

Because the National Hansen's Disease Program may change its recommendations for patient management, clinicians in the United States are advised to seek consultation prior to treating any patient with leprosy (800-642-2477, 225-756-3709). *ND,* No dosing information available; *NHDP,* National Hansen's Disease Program; *WHO,* World Health Organization.

[a]Tuberculoid leprosy, borderline-tuberculoid, and indeterminate

[b]Lepromatous, borderline, and borderline-lepromatous

[c]Higher doses may be used for patients with erythema nodosum leprosum.

[d]Pediatric dosing never should exceed adult maximum. Approximate pediatric dosing,[5] as a percentage of adult dosing, can be estimated at 25% for children <15 kg, 50% if 15 to 30 kg, 75% if 30 to 45 kg, and 100% if >45 kg.

BASIC INFORMATION

DEFINITION

Leptospirosis is a zoonosis caused by the spirochete *Leptospira interrogans.*

SYNONYM

Weil disease

ICD-10CM CODES

A27.9	Leptospirosis, unspecified
A27.0	Leptospirosis icterohemorrhagica
A27.81	Aseptic meningitis in leptospirosis
A27.89	Other forms of leptospirosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- 0.05 cases/100,000 persons
- Significant underestimation because of underreporting
- Hawaii consistently has the highest reported annual incidence rate in the U.S., but outbreaks also have occurred in Puerto Rico

PEAK INCIDENCE: Summer months, into the fall

PREDOMINANT SEX: Male (4:1)

PREDOMINANT AGE: Teenagers and young adults

GENETICS: Neonatal infection can occur.

PHYSICAL FINDINGS & CLINICAL PRESENTATION (SEE TABLE E1, FIG. E1, AND BOX E1)

ANICTERIC FORM:

- Milder and more common presentation of disease
- A self-limited systemic illness with two stages:
  1. Septicemic stage: Presents abruptly with fevers, headache, severe myalgias, rigors, prostration, and sometimes circulatory collapse; conjunctival suffusion is common; skin rash, pharyngitis, lymphadenopathy, hepatomegaly, splenomegaly
  2. Immune stage: Heralded by the production of antibodies, occurs a few days after first stage with similar symptoms and may include kidney disease, jaundice, pneumonitis, hemorrhage, cardiac arrhythmias, headache, and lethargy; hallmark is aseptic meningitis

ICTERIC LEPTOSPIROSIS (WEIL SYNDROME):

- Denotes severe cases, with symptoms of hepatic, renal, and vascular dysfunction
- Biphasic course: Persistence of fever, jaundice, and azotemia
- Complications: Oliguria or anuria, hemorrhage, hypotension, vascular collapse

ETIOLOGY

Caused by a spirochete, *L. interrogans*

- Infects a variety of animals, including most mammals.
- Specific serotypes associated with different hosts—*L. pomona* in livestock, *L. canicola* in dogs, and *L. icterohaemorrhagiae* in rodents.
- Organism penetrates skin or mucous membranes through exposure to animal urine or infected water.
- The most important reservoir for the bacteria is rats.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Bacterial meningitis
- Viral hepatitis
- Malaria
- Dengue fever
- Hanta virus
- Influenza
- Legionnaires' disease

WORKUP

Culture of blood, CSF, and urine:

- Organism can be isolated from blood or CSF during first 10 days of illness.
- Urine should be cultured after first wk and for up to 30 days after onset of illness.
- Serology: MAT (microscopic agglutination test) is considered the gold standard but only available in reference labs. An ELISA is also available as a screening test and a PCR is available in reference labs.

LABORATORY TESTS

- Normal or elevated WBCs, at times with leukemoid reactions up to 70,000/mm^3
- Elevated transaminases or bilirubin
- Anemia, azotemia, hypoprothrombinemia in those with icteric illness
- Elevated CK in first phase
- Meningitis in both phases, but aseptic in second phase

IMAGING STUDIES

Chest x-ray may reveal interstitial nonlobar infiltrates.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Supportive
- Observation for dehydration, hypotension, renal failure, hemorrhage

ACUTE GENERAL Rx

- Severe illness: IV penicillin G 1.5 million units IV q6h (children: 250,000 to 400,000 units/kg IV qd in four to six divided doses) or ceftriaxone 1 to 2 g q24h (children: 80 to 100 mg/kg IV once a day) or doxycycline 100 mg IV q12h (children ≥8: 2 mg/kg per day in two equally divided doses). Treatment should last 7 days.

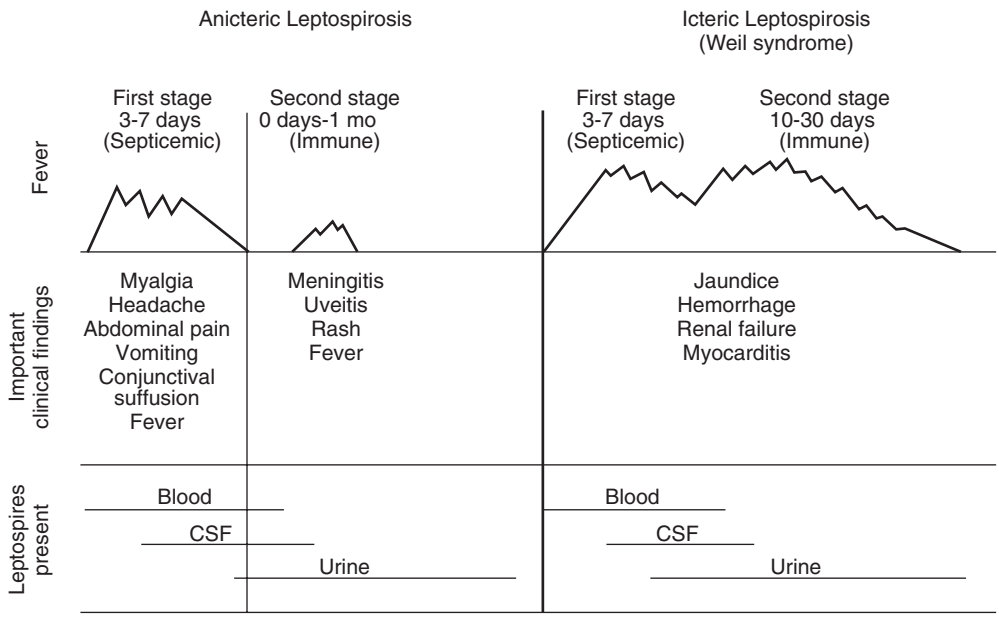

FIG. E1 Clinical course of leptospirosis: Anicteric and icteric disease. *CSF*, Cerebrospinal fluid. (From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.)

BOX E1 Pathophysiology of Specific Clinical Findings in Leptospirosis

Hemolytic Anemia, Jaundice, and Hepatic Injury
- Presence of a hemolysin in the supernate of leptospiral cultures
- Cloned hemolysin of *L. interrogans* serovar Lai demonstrated cell membrane pore-forming activity in vitro
- Thrombocytopenia, depletion of serum prothrombin, depletion of host vitamin K
- Capillary injury, perhaps by toxin
- Hemorrhage of skin or mucosal surfaces and, rarely, gastrointestinal or into a vital organ
- Hepatic manifestations, including jaundice, most likely are the result of hepatocellular injury
- Hemolysis possibly contributing to jaundice
- One or more toxins by leptospires or release of various products after lysis possibly injuring hepatocytes

Renal Injury
- Tubular epithelial cell necrosis, acute vasculitis, segmental thickening of basement membrane, and interstitial edema
- Infiltrates of lymphocytes, monocytes, plasma cells, and neutrophils
- Cells lining the lumen of the renal tubules distended, disorganized, and containing hyaline, granular, epithelial, and bile casts
- Glomeruli showing mesangial hyperplasia, focal fusion of foot processes, swelling of the epithelium in Bowman capsule, and thickening of the basement membrane
- Renal potassium wasting by increased secretion of aldosterone and cortisol
- Tubulointerstitial nephritis, the most common lesion associated with chronic infection
- Leptospires demonstrated in the liver, renal tubules, and interstices of the renal cortex
- Leptospires evading the renal immune system, including absence of complement, downregulation of antigens, delayed lymphocyte infiltration, and delayed colonization of renal tubules
- Impaired renal blood flow leading to nephropathy
- Host response to infection possibly inducing damage as B cells and T cells induce inflammation in the liver and kidneys via a TLR-independent pathway

Pulmonary Involvement
- Pulmonary lesions generally the result of hemorrhage rather than acute inflammation
- Leptospires visualized directly in lung parenchyma
- Alveolar septal deposition of immunoglobulin and complement

Cardiovascular Findings
- Hypovolemia or hypotension from dehydration, bleeding, or third spacing
- Vascular collapse seen with adrenal insufficiency secondary to hemorrhage
- Hypoperfusion, focal hemorrhagic myocarditis, acute coronary arteritis, pericarditis, aortitis, cardiac arrhythmias, congestive heart failure, hypertension, hypovolemia, electrolyte imbalance, or uremia
- Epicardium, endocardium, and myocardium all possibly involved

Ocular Involvement
- Possibly direct *Leptospira*-mediated injury to eye structures, but suggestion that cross-reacting antibodies play a role in *Leptospira*-associated recurrent uveitis

Nervous System Findings
- Meningeal reaction occurs only after the development of antibody; leptospiral meningitis suggested to be a reflection of an antigen-antibody reaction
- Uncommon features of leptospirosis include encephalitis, myelitis, radiculitis, and peripheral neuritis
- Neurologic manifestations attributed to subarachnoid, peripapillary, and subdural hemorrhages

Musculoskeletal Findings
- Myalgia an early clinical feature concurrent with leptospirosis septicemic stage, correlating with the timing of the histologic changes in muscle that often quickly resolve
- Muscle pain that subsides after leptospiral agglutinin titers develop
- Bone involvement in leptospirosis not a significant feature

Other
- No characteristic lesions noted in the adrenal glands, lymph nodes, spleen, gastrointestinal tract, pancreas, ureter, or bladder
- Interstitial edema with monocytic and lymphocytic infiltrates found in testicular tissue associated with impaired spermatogenesis

TLR, Toll-like receptor.
From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

- Mild illness: Doxycycline 100 mg PO bid for 7 days or amoxicillin 25 to 50 mg/kg in three equally divided doses for 7 days or azithromycin 500 mg PO qd for 3 days (children: 10 mg/kg orally on day one then 5 mg/kg per day for 2 days).
- For children ≦8 and pregnant females: Azithromycin or amoxicillin preferred.
- Vitamin K administration if hypoprothrombinemia present.
- Possible Jarisch-Herxheimer reaction when treated with penicillin.

DISPOSITION

- In anicteric leptospirosis, antibiotics can decrease severity and duration of symptoms.
- Icteric leptospirosis, even with supportive therapy, may have a mortality as high as 10%.

REFERRAL

- If more than mild disease
- If no response to treatment

PROPHYLAXIS

- Travelers at increased risk for infection may be given weekly chemoprophylaxis with doxycycline 200 mg once/wk, beginning 1 to 2 days before and continuing throughout the period of exposure.

BASIC INFORMATION

DEFINITION

Rectal pain, described as a dull ache or pressure high in the rectum, typically worse when sitting

SYNONYMS

Levator spasm
Puborectalis syndrome
Chronic proctalgia
Pelvic tension myalgia
Levator syndrome
Proctodynia

ICD-10CM CODE
K59.4 Anal Spasm

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Unknown
PREVALENCE: 6.6%, by survey
PREDOMINANT SEX AND AGE: Unknown
PEAK INCIDENCE: Unknown
RISK FACTORS: Middle age (30 to 60), Women
GENETICS: Unknown

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Diagnostic Criteria for Levator Ani Syndrome:

1. Chronic or recurrent rectal pain or aching
2. Episodes last 30 min or longer
3. Tenderness during traction on the puborectalis
4. Exclusion of other causes of rectal pain, such as inflammatory bowel disease, intramuscular abscess and fissure, thrombosed hemorrhoids, prostatitis, coccygodynia, and major structural alterations of the pelvic floor
5. Criteria fulfilled for the last 3 mo with symptom onset at least 6 mo before diagnosis

ETIOLOGY

Unclear, but hypothesized to be secondary to spasm of the pelvic floor muscles and elevated anal resting pressures. Alternative hypothesis of dyssynergic defecation as the cause

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Proctalgia fugax
- Unspecified anorectal pain
- Inflammatory bowel disease
- Intramuscular abscess and fissure
- Thrombosed hemorrhoids
- Prostatitis
- Coccygodynia and major structural alterations of the pelvic floor

Differentiation among the three anorectal pain disorders (levator ani syndrome, proctalgia fugax, and unspecified) can be confusing. There is a great deal of overlap in the conditions, which are distinguished by the duration of pain and presence of rectal tenderness.

- Levator ani syndrome: Episodes last more than 30 min; presence of rectal tenderness between episodes
- Proctalgia fugax: Episodes last less than 30 min; no rectal tenderness between episodes
- Unspecified: Does not fit into the above categories

WORKUP

Often can be diagnosed by history and presenting symptoms. Consider additional testing (e.g., stool studies, sigmoidoscopy, ultrasonography, and MRI) to exclude alternative diagnosis.

LABORATORY TEST

Stool studies if concerned about alternative diagnosis

IMAGING STUDIES

- Sigmoidoscopy
- Ultrasonography
- MRI if concerned about alternative diagnosis

TREATMENT

NONPHARMACOLOGIC THERAPY

- Combination of digital massage of the levator ani muscles, sitz baths, and biofeedback
- Massage consists of teaching patients twice a day, after sitz bath, to insert a finger into the anal sphincter and rotate the finger back and forth with as much force as tolerable.
- Biofeedback consists of teaching patients proper straining methods followed by effective pelvic floor relaxation while being monitored by an intra-anal electromyography probe. This is followed by counseling sessions to help patients identify possible triggers for the pain and effective strategies to avoid or cope with these triggers.

ACUTE GENERAL Rx

Muscle relaxants (methocarbamol, diazepam, cyclobenzaprine); best used in combination with massage, sitz baths, and biofeedback

CHRONIC Rx

Same as acute treatment

COMPLEMENTARY AND ALTERNATIVE MEDICINE

- Electrogalvanic stimulation: Found inferior to the above combination treatment
- Botulinum toxin injections into the levator ani muscles: Results similar to placebo injections

DISPOSITION

Outpatient treatment

REFERRAL

- Biofeedback therapy
- Behavioral counseling

PEARLS & CONSIDERATIONS

COMMENTS

Given the nature of the syndrome and pain, patients may be hesitant to discuss their concerns. Furthermore, the nature of treatment therapies may discourage compliance.

PREVENTION

None known

Lichen Planus PTG

BASIC INFORMATION

DEFINITION

Lichen planus (LP) refers to an idiopathic inflammatory disease manifesting with a papular skin eruption characteristically found over the flexor surfaces of the extremities, genitalia, and mucous membranes.

SYNONYMS

Lichen
Lichen planus et atrophicus
LP

ICD-10CM CODES

L43	Lichen planus
L43.0	Hypertrophic lichen planus
L43.1	Bullous lichen planus
L43.9	Lichen planus, unspecified
L43.8	Other lichen planus

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: One in every 100 new patients seen in dermatology clinics in the United States is diagnosed with LP.
PREVALENCE: 440 cases/100,000 persons
PREDOMINANT SEX: Found equally between males and females (1:1)
PREDOMINANT AGE: Usually found in people between the ages of 30 and 60 yr
PREDISPOSING FACTORS:

- Associated with other autoimmune disorders (e.g., primary biliary cirrhosis, myasthenia gravis, ulcerative colitis, diabetes)
- Associated with hepatitis C infection
- Drug-induced form affects any area of the body surface (e.g., beta-blocker, methyldopa, penicillamine, quinidine, nonsteroidal antiinflammatory drugs, angiotensin-converting enzyme inhibitors, sulfonylurea agents)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Lichen planus often manifests with pruritic, flat-topped violaceous papules but the clinical presentation varies depending on the area involved.

History:

- Usually starts on an extremity and may remain localized or spread to involve other areas over a 1- to 4-mo period
- Pruritic

Physical findings:

- Anatomic distribution:
  1. Flexor surface of wrists, forearms, shins, and upper thighs
  2. Neck and back area
  3. Nails (5% to 10% of patients)
  4. Scalp (lichen planopilaris)
  5. Oral mucosa, buccal mucosa, tongue, gingiva, and lips; oral lichen planus can cause extensive desquamative gingivitis
  6. Vulva (Fig. E1), penis (Fig. E2)

Genital mucosa:

- Lesion configuration:
  1. Linear
  2. Annular (more common)
  3. Reticular pattern noted on oral mucosa and genital area
- Lesion morphology:
  1. Papules most common presentation (flat, smooth, shiny) (Fig. E3)
  2. Hypertrophic
  3. Follicular
  4. Vesicular
- Color:
  1. Dark red, bluish red, purplish-violaceous color is noted in cutaneous LP (Fig. E4).
  2. Individual lesions characteristically have white lines visible (Wickham striae) (Fig. E5).
  3. Oral and genital LP has a reticular network of white lines that may be raised or annular in appearance (Fig. E6).

- Scalp lesions may result in alopecia.
- The plaques of lichen planus may be hypertrophic but show the characteristic violaceous coloration and intense hyperpigmentation (Fig. E7).

ETIOLOGY

Lichen planus is characterized by an immunologic reaction mediated by CD8+ T cells. These cells induce keratinocytes to undergo apoptosis. Although the inflammatory reaction is believed to be autoimmune, the antigen targeted by these effector T lymphocytes is unknown.

FIG. E1 Lichen planus of the vulva with a white, lacelike pattern and erythema. (From Crum CP et al: *Diagnostic gynecologic and obstetric pathology*, ed 3, Philadelphia, 2018, Elsevier.)

FIG. E2 Lichen planus of the penis. (From Swartz MH: *Textbook of physical diagnosis, history and examination,* ed 7, Philadelphia, 2014, Saunders.)

FIG. E3 Flat-topped, purple, polygonal papules of lichen planus. (From Morelli JG: Diseases of the epidermis. In Kliegman RM et al [eds]: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, Saunders.)

FIG. E4 Shiny, flat-topped, polygonal, violaceous papules of lichen planus. Note the Wickham striae (linear, whitish-gray streaks) on the surface. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, 2016, Elsevier.)

Dx DIAGNOSIS

- Clinical history and physical findings usually establish the diagnosis of LP.
- Skin biopsy (deep shave or punch biopsy of the most developed lesion) can be performed to confirm the diagnosis.

DIFFERENTIAL DIAGNOSIS

- Drug eruption, psoriasis, Bowen disease, leukoplakia, candidiasis, lupus rash, secondary syphilis, seborrheic dermatitis, chronic graft-versus-host disease
- Table E1 summarizes variants of lichen planus

WORKUP

If the diagnosis is questionable, a skin biopsy is performed.

LABORATORY TESTS

Laboratory tests are not specific for the diagnosis of LP. Lipid panels screening is useful since increases in serum triglycerides and decreases in HDL cholesterol are common in patients with LP.

IMAGING STUDIES

Imaging studies are not helpful in diagnosing LP.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoid scratching.
- Use mild soaps and emollients after bathing to prevent dryness.

GENERAL Rx

FOR CUTANEOUS LP:

- Topical steroids (e.g., triamcinolone acetonide 0.1%, fluocinonide 0.05%, clobetasol propionate 0.05% cream or ointment) with occlusion used twice daily
- Acitretin 30 mg/day PO for 8 wk
- Systemic prednisone 30 to 60 mg/day as a starting dose and tapered to 15 to 20 mg/day maintenance for 6 wk can be used for widespread lesions
- Intradermal steroid triamcinolone acetonide 5 mg/ml can be tried for thick hyperkeratotic lesions
- Hydroxyzine 25 mg PO q6h can be used for pruritus
- Phototherapy: PUVA or narrow-band ultraviolet B therapy: 2 or 3 times per wk, for a total of 12 sessions (i.e., one cycle)

FOR ORAL LP:

- Topical steroid fluocinonide in an adhesive base used six times/day for 9 wk
- Topical calcineurin in steroid-unresponsive cases
- Topical or systemic retinoids 0.1% retinoic acid in an adhesive base or gel
- Etretinate 75 mg/day for 2 mo

DISPOSITION

- Spontaneous remissions of cutaneous LP occur in >65% of cases within the first year.
- Spontaneous remission of oral LP usually occurs by 5 yr.
- Approximately 10% to 20% of patients will have recurrence.

REFERRAL

To dermatologist if diagnosis is unclear

! PEARLS & CONSIDERATIONS

COMMENTS

- LP can be remembered as purple, planar, pruritic, polygonal, papules, and plaques (six Ps).
- Lesions can develop at the site of prior skin injury (Koebner phenomenon).
- Although there is an increased risk of squamous cell carcinoma in chronic lesions of mucosal LP, transformation to skin cancer is uncommon.

Lichen Planus (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

FIG. E5 A and **B,** Lichen planus. Note the fine, reticulated white scales. (Swartz MH: *Textbook of physical diagnosis, history and examination,* ed 7, Philadelphia, 2014, Saunders.)

FIG. E6 Oral lichen planus. Wickham striae on the buccal mucosa. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, 2016, Elsevier.)

FIG. E7 Lichen planus. The plaques of lichen planus may be hypertrophic but show the characteristic violaceous coloration and intense hyperpigmentation. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, 2016, Elsevier.)

TABLE E1 Variants of Lichen Planus

Variant Type	Characteristics
Bullous	Bullae develop on existent LP lesions
LP pemphigoides	LP + bullous pemphigoid with autoimmune reactivity, usually against type XVII collagen (bullous pemphigoid 180 antigen)
Actinic	Onset during spring, summer; primarily sun-exposed surfaces (face, neck, dorsum of arms and hands); often annular configuration; most common in children and young adults
Annular	Occur in 10% of patients, often scattered amid typical lesions of LP
Hypertrophic	Thick, pruritic, hyperkeratotic plaques, especially on the legs and dorsal regions of the feet; persistent
Atrophic	May represent a resolving phase in which larger plaques become centrally depressed with residual hyperpigmentation
Hemorrhagic/purpuric	Shows nonblanching component on diascopy
Linear	LP occurring spontaneously along the lines of Blaschko; presumably reflects somatic mosaicism
Erosive/ulcerative	Intensely painful ulcerations on the palms and soles; chronic lesions may evolve into squamous cell carcinoma; erosive lesions may occur on mucosal surfaces
LP/lupus erythematosus	Overlapping features of lupus and LP; lesions are usually acral and patients may show high titers of ANA
Lichen planopilaris	Follicular LP; keratotic plugs surrounded by violaceous erythema, especially on scalp but can affect any hair-bearing area; usually results in cicatricial alopecia

ANA, Anti-nuclear antibodies; *LP,* lichen planus.
From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, 2016, Elsevier.

Lichen Sclerosus

BASIC INFORMATION

DEFINITION

Lichen sclerosus (LS) is a chronic inflammatory condition of the skin usually affecting the vulva, penis, perianal area, and groin.

SYNONYMS

Lichen sclerosus et atrophicus
Kraurosis vulvae
Balanitis xerotica obliterans
LS

ICD-10CM CODE
L90.0 Lichen sclerosus et atrophicus

EPIDEMIOLOGY & DEMOGRAPHICS

- Most common in postmenopausal women and men between ages 40 and 60 yr.
- More common in females (female:male ratio of 5:1). It affects 1.7% of the general adult female population.
- Can occur in children (usually prepubertal girls with involvement of the vulva and perineum).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Erythema may be the only initial sign. A characteristic finding is the presence of ivory-white atrophic lesions on the involved area.
- Close inspection of the affected area will reveal the presence of white-to-brown follicular plugs on the surface (dells).
- When the genitals are involved, the white, parchment-like skin assumes an hourglass configuration around the introital and perianal area ("keyhole" distribution; Fig. E1, Fig. E2). Inflammation, subepithelial hemorrhages, and chronic ulceration may develop.
- In males, lesions are atrophic and may be hypopigmented or depigmented, resembling vitiligo. Phimosis and paraphimosis are common complications in uncircumcised males with LS.
- Lesions may be surrounded by an erythematous to violaceous halo.
- Dyspareunia, genital bleeding, and anal bleeding are common.
- Pruritus may be a prominent symptom.

ETIOLOGY

Unknown. There may be an autoimmune association and a genetic familial component.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Localized scleroderma (morphea)
- Cutaneous discoid lupus erythematosus
- Atrophic lichen planus
- Psoriasis
- Lichen simplex chronicus
- Vulvar intraepithelial neoplasm
- Extramammary Paget disease
- Table E1 summarizes the differential diagnosis of common vulvar mucocutaneous disorders

WORKUP

Diagnosis is based on close examination of the lesions for the presence of ivory-white atrophic lesions and typical location.

LABORATORY TESTS

- Punch or deep shave biopsy can be used to confirm the diagnosis.
- Autoantibodies to extracellular matrix protein 1 (ECM-1) are present in 80% of LS patients and the ECM-1 titer correlates with disease activity.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Attention to hygiene and elimination of irritants or excessive bathing with harsh soaps.
- Cryotherapy and photodynamic therapy can be used in refractory cases.

GENERAL Rx

- Application of clobetasol propionate 0.05% topically bid for up to 4 wk is usually effective. Repeat courses of corticosteroids may be necessary because of the chronic nature of this disorder. Continual application of topical steroids may lead to atrophy of the vulva.
- There is no substantial evidence that use of topical sex hormones (e.g., topical testosterone [2%]) is effective in genital lichen sclerosus.
- Lubricants (e.g., Nutraplus cream) are useful to soothe dry tissues.
- Hydroxyzine 25 mg at bedtime is effective in decreasing nocturnal itching.
- Use of intralesional steroids, etretinate, and surgical management is usually reserved for refractory cases.

DISPOSITION

- The disease persists in approximately one third of patients.
- Most prepubertal girls improve spontaneously at menarche.
- Squamous cell carcinoma can develop within the lesions in 3% to 10% of older patients; therefore periodic examination and biopsy of suspicious areas are indicated.

PEARLS & CONSIDERATIONS

COMMENTS

- Prepubertal lichen sclerosus may be confused with sexual abuse in prepubertal girls and may lead to false accusations and investigations.
- Pregnancy leads to improvement and often complete resolution of lesions, suggesting a hormonal component to etiology of lesions.

FIG. E1 Lichen sclerosus with stenosis of the introitus, fissuring in the posterior fourchette, and perianal involvement producing the "keyhole appearance." (Fishe BK and Margesson LJ: Genital skin disorders: Diagnosis and treatment. In Disaia PJ et al: *Clinical gynecologic oncology*, ed 9, Philadelphia, 2017, Elsevier.)

FIG. E2 A, Clinical appearance of lichen sclerosus. Note the atrophy of the labium minus. **B,** Lichen sclerosus with a prominent hourglass appearance. (From Crum CP et al: *Diagnostic gynecologic and obstetric pathology*, ed 3, Philadelphia, 2018, Elsevier.)

- Lichen sclerosus of the vulva (kraurosis vulvae) usually occurs after menopause and is generally chronic. It can be painful and interfere with sexual activity.
- Lichen sclerosus of the penis (balanitis xerotica obliterans) is seen more commonly in uncircumcised males. It affects the glans and prepuce and may lead to stricture if it encroaches into the urinary meatus.

Lichen Simplex Chronicus

BASIC INFORMATION

DEFINITION

Lichen simplex chronicus (LSC) is neurodermatitis manifesting with localized areas of thickened, hyperplastic scaly skin due to prolonged and severe scratching in patients with no underlying dermatologic condition.

SYNONYMS

LCS
Neurodermatitis from rubbing
Circumscribed neurodermatitis

ICD-10CM CODE
L28.0 Lichen simplex chronicus

EPIDEMIOLOGY & DEMOGRAPHICS

PEAK INCIDENCE: Between 35 and 50 yr old
PREVALENCE: Increased in patients with underlying anxiety disorders
PREDOMINANT SEX AND AGE:
- Sex: Females > males (2:1)
- Age: Adults over 60

RISK FACTORS: Anxiety disorders, dry skin, insect bites

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients present with profound pruritus and localized scaly plaques with accentuated skin markings said to resemble tree bark.
- Lichenified circumscribed plaques. Trauma from rubbing and scratching accounts for persistence of the plaque.
- Commonly involved areas include hands and wrists, back and sides of neck (Fig. E1), anterior tibias, anogenital areas (Fig. E2), the scalp, the upper eyelid, the orifices of both ears, and ankles.

ETIOLOGY

- Neurodermatitis due to long-term chronic rubbing and scratching more vigorously than a normal pain threshold would allow, resulting in thickened and leathery skin.
- Common triggers are excess dryness of skin, heat, sweat, and psychological stress. It can also accompany other conditions such as obsessive-compulsive disorder, the fungal infections candidiasis or tinea cruris, or psoriasis, lichen sclerosus, and neoplasia, leading to squamous cell hyperplasia.
- Other causes include atrophic dermatitis and insect bites. Rare cases have shown links to lithium use, hair dye containing PPD, and long-term exposure to vehicle pollution.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Lichen planus
- Psoriasis
- Atopic dermatitis
- Insect bite
- Nummular eczema
- Contact dermatitis
- Stasis dermatitis

WORKUP

Patient history and skin examination. Skin biopsy when diagnosis is unclear or persistent symptoms.

LABORATORY TESTS

- Not generally necessary.
- Biopsy reveals hyperkeratosis, acanthosis, and mild to moderate lymphohistiocytic inflammatory infiltrate with prominent lichenification.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Patient education is essential to break the itch-scratch cycle and facilitate treatment of any underlying dermatitis.
- Psychotherapy.

ACUTE GENERAL Rx

- Cessation of pruritus is the goal. Antihistamine hydroxyzine 25 mg at bedtime is effective in decreasing nocturnal itching. Moisturizers are also helpful
- High-potency topical corticosteroids can be used initially but not indefinitely because of potential for steroid-induced atrophy
- Steroid-containing tape may be effective in providing both occlusion and antiinflammatory effect
- Intralesional corticosteroids
- Anxiolytics, SSRIs
- Oral doxepin (an antidepressant and anxiolytic)
- Mirtazapine
- Tropical calcineurin inhibitor for vulvar lichenification
- Cyclosporin A
- Topical tacrolimus, 0.1% ointment, can be used for sensitive skin, face
- Botulinum intradermal injections
- Alitretinoin, 30 mg daily for 3 mo, has shown some clinical improvement in case studies but needs further investigation as a potential Rx

CHRONIC Rx

Constant irritation of the skin must be avoided. Keeping skin moisturized, covering to prevent scratching, or filing nails may be necessary.

DISPOSITION

Psychological intervention improves recovery. Regular follow-up visits facilitate long-term management.

REFERRAL

Refer to a psychologist for psychological evaluation and consultation, and a dermatologist in resistant cases.

PEARLS & CONSIDERATIONS

- Significant scratching may occur during nocturnal hours.
- The involved area is always at a site that is easily reached for scratching.
- Chronic scratching can also cause keratinocyte necrosis and the development of amyloid in the papillary dermis, called lichen amyloidosis.

COMMENTS

Patients may be at increased risk for scarring of the skin, changes in skin pigmentation, and bacterial and fungal infections of the involved skin.

PREVENTION

Prevent future incidences by continued therapy, stress management, and avoidance of common triggers and accompanying conditions.

AUTHORS: **Fred F. Ferri, MD,** and **Heather Ferri, DO**

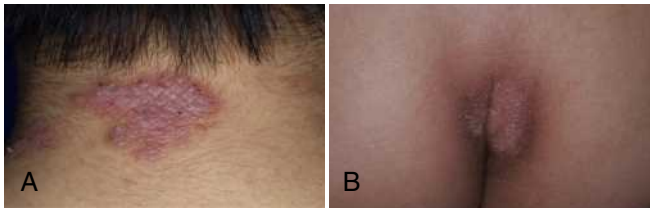

FIG. E1 (**A** and **B**) Lichen simplex chronicus. Localized plaques of dermatitis that result from repeated scratching and rubbing of the involved area. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence*, ed 5, 2016, Elsevier.)

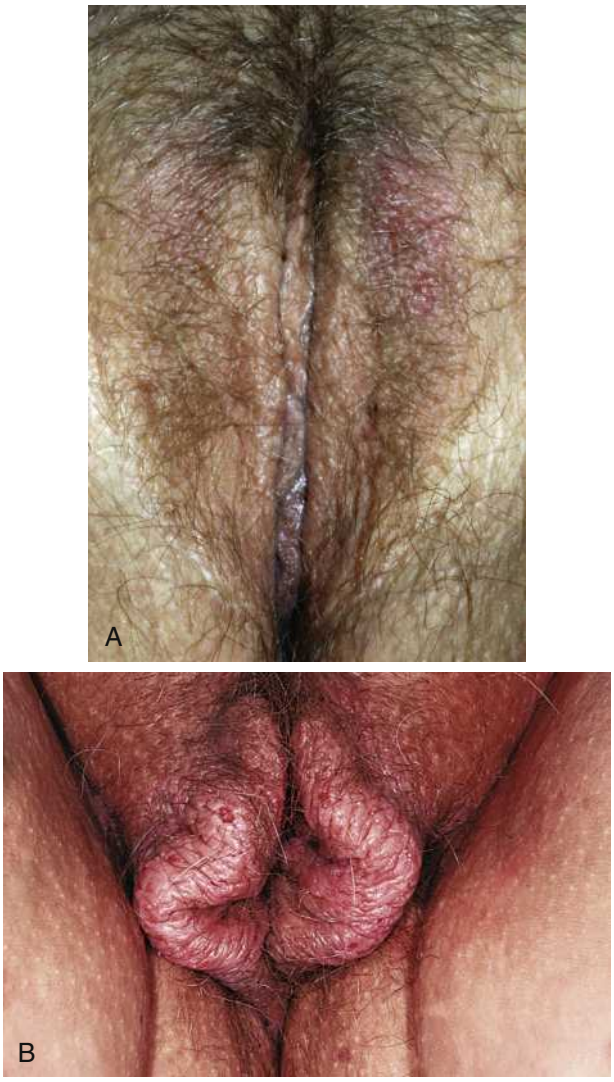

FIG. E2 A, Lichen simplex chronicus is characterized clinically by thickening of the mucosa, lending a leathery appearance that often is discolored (as in this case). **B,** Lichen simplex chronicus with pronounced changes associated with itch-scratch cycle. (From Crum CP et al: *Diagnostic gynecologic and obstetric pathology*, ed 3, Philadelphia, 2018, Elsevier.)

BASIC INFORMATION

DEFINITION

Listeriosis is a systemic infection caused by the gram-positive aerobic bacterium *Listeria monocytogenes.* The range of clinical syndromes varies from gastroenteritis to life-threatening meningitis and tends to be more severe in immunocompromised patients and in patients who are pregnant.

SYNONYMS

Listerial infection
Granulomatosis infantisepticum

ICD-10CM CODES

A32	Listeriosis
A32.0	Cutaneous listeriosis
A32.11	Listeria meningitis
A32.81	Oculoglandular listeriosis
A32.89	Other forms of listeriosis
P37.2	Neonatal (disseminated) listeriosis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- *Listeria* meningitis: About 0.7 cases/100,000 persons (fourth most common cause of community-acquired bacterial meningitis in adults)
- In pregnant women: 3.0 cases per 100,000 population
- In general population: 0.29 confirmed cases per 100,000 persons in 2009 to 2011 in the United States, but 1.3 per 100,000 cases in persons over the age of 65
- Approximately 800 lab-confirmed cases are reported in the U.S. annually

PREDOMINANT SEX: Pregnant women are more susceptible to *Listeria* bacteremia, accounting for up to one third of reported cases.

PREDOMINANT AGE:

- Pregnant women
- Immunocompromised patients of any age
- Elderly patients are susceptible even in the absence of recognized immunocompromised states

GENETICS: Congenital infection:

- With transplacental transmission, syndrome termed *granulomatosis infantisepticum* in neonate
- Characterized by disseminated abscesses in multiple organs, skin lesions, and conjunctivitis
- Mortality: 33% to 100%

Neonatal infection:

- Infant becoming ill after 3 days of age; mother invariably asymptomatic
- Clinical picture is of sepsis of unknown origin

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Infections in pregnancy
  1. More common in third trimester
  2. Usually present with fever and chills without localizing symptoms or signs of infection
- Meningoencephalitis
  1. More common in neonates and immunocompromised patients, but up to 30% of adults have no underlying condition
  2. In neonates: Poor appetite with or without fever possibly the only presenting signs
  3. In adults: Presentation often subacute, with low-grade fever and personality change as only signs
  4. Focal neurologic signs seen without demonstrable brain abscess on CT scan
- Cerebritis/rhombencephalitis
  1. Headache and fever may be only presenting complaints
  2. Progressive cranial nerve palsies, hemiparesis, seizures, depressed level of consciousness, cerebellar signs, respiratory insufficiency may also be seen
- Focal infections
  1. Ocular infections (purulent conjunctivitis) and skin lesions (granulomatosis infantisepticum) as a result of inadvertent inoculation by laboratory and veterinary personnel
  2. Others: Arthritis, prosthetic joint infections, peritonitis, osteomyelitis, organ abscesses, cholecystitis

ETIOLOGY

- Listeria is a gram-positive rod that acts as a facultative intracellular parasite that helps protect the cell from host innate and adaptive immune responses. The primary habitat for the bacterium is soil and decaying vegetable matter.
- Listeria is a hardy organism that can withstand a wide range of conditions including refrigeration (can grow at standard refrigerated temperature of 40 degrees Fahrenheit), freezing, heat, and relatively high levels of acid, salinity and alcohol.
- Incubation period is between 11 and 70 days, with a mean of 31 days.
- Direct invasion of skin and eye has been documented, but most cases involve GI tract at the level of the intestine, with Listeria crossing the mucosal barrier by active endocytosis of the bacteria by endothelial cells. Once in the bloodstream, the organism can disseminate to any site, with a predilection for CNS and placenta.
- Organism's intracellular life cycle explanatory of:
  1. Importance of cell-mediated immunity in host defense
  2. Increased infection in neonates, pregnant women, and immunocompromised hosts

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Meningitis caused by other bacteria, mycobacteria, or fungi
- CNS sarcoidosis
- Brain neoplasm or abscess
- Tuberculous and fungal (especially cryptococcal) meningitis
- Cerebral toxoplasmosis
- Lyme disease
- Sarcoidosis

LABORATORY TESTS

- Cultures of blood and other appropriate body fluids
- Variable CSF findings, but neutrophils usually predominate
- Organisms uncommonly seen on Gram stain and may be difficult to identify morphologically
- Monoclonal antibodies, polymerase chain reaction, and DNA probe techniques to detect *Listeria* in foods

IMAGING STUDIES

- If focal cerebral involvement suspected: CT scan or MRI
- MRI most sensitive for evaluation of brainstem and cerebellum

TREATMENT

Empiric therapy should be administered when diagnosis is suspected because overall mortality is 23%.

ACUTE GENERAL Rx

- Drugs of choice: Meningitis, meningoencephalitis and bacteremia
  1. IV ampicillin 2 g IV q 4 hr for adults. Children: 300 mg/kg per day IV in 4 to 6 divided doses. Infants 8 days to 1 mo: 150 to 200 mg/kg per day divided in four doses. For infants ≤7 days: 100 mg/kg per day divided in two doses for infants weighing <2000 g and 150 mg/kg per day divided in three doses for infants weighing more than 2000 g.
  2. IV penicillin 12 to 24 million U/day in divided doses in adults.
- Continuation of therapy for 2 wk for bacteremia; 2 to 4 wk for meningitis.
- Alternative (if penicillin allergic): Trimethoprim/sulfamethoxazole (10 to 20 mg/kg based on trimethoprim component) IV per day divided every 6 to 12 hr or meropenem: 1 gram IV q 8 hrs if PCN allergy not IgE mediated.
- Gentamicin IV added to provide synergy in meningitis or endocarditis patients of any age (adults: 3 mg/kg per day IV in three divided doses and for children and infants will depend on age and weight).
- For febrile gastroenteritis: In immunocompetent hosts, spontaneous resolution occurs in less than 2 days, so no treatment is required. In immunocompromised, elderly, or pregnant patients: Amoxicillin 500 mg po TID x3 to 5 days or Bactrim DS: 1 tablet po BID x3 to 5 days

CHRONIC Rx

Relapses reported, especially in immunocompromised hosts, after 2 wk of therapy.

REFERRAL

Infectious disease consultation for all patients

PEARLS & CONSIDERATIONS

COMMENTS

- Foodborne cases have been linked to various products in recent years: Coleslaw, soft cheeses, unpasteurized milk and milk products, vegetables, undercooked chicken, hot dogs, luncheon meats, refrigerated smoked seafood, caramel apples, cantaloupes, and so on.
- Complete decontamination of food products is difficult because *Listeria* is resistant to pasteurization and refrigeration.
- Immunocompromised states include glucocorticoid use, anti-TNF therapies, malignancies (hematologic and solid), AIDS, end-stage renal disease, iron overload, collagen vascular diseases, liver disease, and alcoholism.

BASIC INFORMATION

DEFINITION

Liver abscess is a necrotic infection of the liver usually classified as pyogenic or amebic.

SYNONYMS

Pyogenic hepatic abscess
Amebic hepatic abscess

ICD-10CM CODE
K75.0 Abscess of liver

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Incidence of pyogenic liver abscess is 2.3 cases per 100,000 population.
PREVALENCE (WORLDWIDE): Amebic liver abscess is more common than pyogenic liver abscess.
PREVALENCE (IN U.S.): Pyogenic liver abscess is more common than amebic liver abscess.
PREDOMINANT SEX AND AGE: More common in men than women; male/female ratio of 2:1; most common in fourth to sixth decades of life.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Fever, chills, and sweats
- Weakness/malaise
- Anorexia with weight loss
- Nausea, vomiting, and diarrhea
- Cough with pleuritic chest pain
- Right upper quadrant abdominal pain
- Hepatomegaly
- Splenomegaly
- Jaundice
- Pleural effusions, rales, and friction rubs may be present
- Most abscesses occur on the right lobe of the liver

ETIOLOGY

- Pyogenic liver abscess is usually polymicrobial (*Klebsiella pneumoniae* [43%], *Escherichia coli* [33%], *Streptococcus* spp. [37%], *Pseudomonas aeruginosa, Proteus* spp., *Bacteroides* spp. [24%], *Fusobacterium* spp., *Actinomyces* spp., gram-positive anaerobes, and *Staphylococcus aureus*).
- Pyogenic liver abscess occurs from:
  1. Biliary disease with cholangitis (accounts for approximately 40% to 60%).
  2. Gallbladder disease with contiguous spread to the liver.
  3. Diverticulitis or appendicitis with spread via the portal circulation.
  4. Hematogenous spread via the hepatic artery, though uncommon; if a solitary organism is isolated, a distant source of hematogenous seeding should be sought.
  5. Penetrating wounds.
  6. Cryptogenic.
  7. Infection by way of portal system (portal pyemia).
  8. No causes found in approximately half of cases.
  9. Incidence increased in patients with diabetes and metastatic cancer.
  10. Table 1 summarizes underlying etiology and bacteriology of liver abscesses.
- Amebic hepatic abscess is caused by the parasite *Entamoeba histolytica*. Amebiasis is usually due to fecal-oral contamination and invades the intestinal mucosa, gaining entry into the portal system to reach the liver. Amebic abscess occurs in 3% to 7% of patients with amebiasis.
- A comparison of pyogenic and amebic liver abscess is summarized in Table 2.

Box 1 describes pearls for amebic liver abscesses. The abscess is usually solitary (85%) and in the right lobe (72%).

DIAGNOSIS

The diagnosis of liver abscess requires a high index of suspicion after a detailed history and physical examination. Imaging studies and microbiologic, serologic, and percutaneous techniques (e.g., aspiration) confirm the presence of a liver abscess.

TABLE 1 Underlying Etiology and Bacteriology

Etiology	Bacteriology
Biliary, benign	*Escherichia coli* *Klebsiella* spp. *Enterococcus*
Biliary, malignant	*Pseudomonas* spp. Multiply resistant GN aerobes VRE Yeast
Diverticulitis/appendicitis	GN aerobes *Bacteroides fragilis*
Severe cholecystitis	See Biliary, benign *Clostridium perfringens* *Bacteroides* spp.
Subcutaneous abscess	*Staphylococcus* spp. MRSA
Endocarditis	*Enterococcus* spp. *Staphylococcus* spp.
Cryptogenic	Anaerobes

GN, Gram-negative; *MRSA*, methicillin-resistant *Staphylococcus aureus*; *VRE*, Vancomycin-resistant *Enterococcus*.
From Cameron, JL, Cameron AM: *Current surgical therapy*, ed 10, Philadelphia, 2011, Saunders.

DIFFERENTIAL DIAGNOSIS

- Cholangitis
- Cholecystitis
- Diverticulitis
- Appendicitis
- Perforated viscus
- Mesentery ischemia
- Pulmonary embolism
- Pancreatitis

WORKUP

- The workup of a liver abscess should focus on differentiating between amebic and pyogenic causes.
- Features suggesting an amebic cause include travel to an endemic area, single abscess rather than multiple abscesses, subacute onset of symptoms, and absence of conditions predisposing to pyogenic liver abscess, as highlighted under "Etiology."
- Laboratory studies are not specific but are useful as adjunctive tests.
- Imaging studies cannot differentiate between the two, and bacteriologic cultures may be sterile in 50% of the cases.

LABORATORY TESTS

- Complete blood count: Leukocytosis
- Liver function tests: Alkaline phosphatase is most commonly elevated (95% to 100%); aspartate transaminase (AST) and alanine transaminase (ALT) elevated in 50% of cases; elevated bilirubin (28% to 30%); decreased albumin
- Prothrombin time (INR): Prolonged (70%)
- Blood cultures: Positive in 50% of cases
- Aspiration (50% sterile)
- Stool samples for *E. histolytica* trophozoites (positive in 10% to 15% of amebic liver abscess cases)
- Serologic testing for *E. histolytica* should be done on all patients, but it is important to remember that it does not differentiate acute from old infections

IMAGING STUDIES

- Ultrasound (80% to 100% sensitivity in detecting abscesses) shows round or oval hypoechogenic mass (Fig. E1, *A*).

TABLE 2 Comparisons of Pyogenic and Amebic Liver Abscess

Parameter	Pyogenic Liver Abscess	Amebic Liver Abscess
Number	Often multiple	Usually single
Location	Either lobe of liver	Usually right hepatic lobe, near the diaphragm
Presentation	Subacute	Acute
Jaundice	Mild	Moderate
Diagnosis	US or CT ± aspiration	US or CT and serology
Treatment	Drainage (if technically feasible) + IV antibiotics (see text)	Metronidazole, 750 mg 3 times daily for 7-10 days orally or IV; or tinidazole, 2 g orally for 3 days, followed by iodoquinol, 650 mg orally 3 times daily for 20 days; diloxanide furoate, 500 mg orally 3 times daily for 10 days; or aminosidine (paromomycin) 25-35 mg/kg/day orally in 3 divided doses for 7-10 days

CT, Computed tomography; *IV*, intravenous; *US*, ultrasonography.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

BOX 1 Pearls for Amebic Liver Abscesses

- Only 10%-20% of patients with amebic liver abscess have a history of diarrhea.
- Treat the intestinal infection to prevent relapse of amebic liver abscess. Failure to use luminal amebicidal agents after metronidazole in cases of amebic abscess results in a 10% relapse rate.
- Failure to show response to antiamebic medication requires evaluation for polymicrobial infection with bacteria.
- Amebic abscess usually responds clinically to antimicrobial therapy in 3 to 7 days, although imaging takes several mo to show resolution.
- Percutaneous drainage is rarely required.

From Cameron, JL, Cameron AM: *Current surgical therapy*, ed 10, Philadelphia, 2011, Saunders.

- CT scan is more sensitive in detecting hepatic abscesses and contiguous organ extension and is the imaging study of choice (Fig. E1, *B,* and Fig. E2).
- Chest x-ray: Abnormal in 50% of the cases, may reveal elevated right hemidiaphragm, subdiaphragmatic air-fluid levels, pleural effusions, and consolidating infiltrates.
- Most liver abscesses are single; however, multiple liver abscesses can occur with systemic bacteremia.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- The management of pyogenic liver abscess differs from that of amebic liver abscess.
- Medical management is the cornerstone of therapy in amebic liver abscess, whereas early intervention in the form of surgical therapy or catheter drainage and parenteral antibiotics is the rule in pyogenic liver abscess greater than 3 cm. Smaller abscesses (<3 cm) can generally be treated with broad-spectrum antibiotics.

ACUTE GENERAL Rx

- Percutaneous drainage under CT or ultrasound guidance is essential in the treatment of pyogenic liver abscesses.
- Aspiration of hepatic amebic abscesses is not required unless there is no response to treatment or a pyogenic cause is being considered.
- Empiric broad-spectrum antibiotics are recommended initially until culture results are available. Common choices include:
  1. Metronidazole (500 mg IV q8h) plus ceftriaxone or levofloxacin.
  2. Monotherapy with a beta-lactam/beta-lactamase inhibitor, such as piperacillin/tazobactam (4.5 g q6h), ticarcillin-clavulanate (3.1 g q4h), or ampicillin-sulbactam (3 g q6h).
  3. Monotherapy with a carbapenem, such as imipenem (500 mg IV q6h), meropenem (1 g q8h), or ertapenem (1 g daily).
  4. Duration of antibiotic treatment is usually 4 to 6 wk with IV antibiotics used for the first 1 to 2 wk or until a favorable clinical response, followed thereafter with oral antibiotics (e.g., metronidazole 500 mg PO q8h plus ciprofloxacin 500 mg PO q12h).
  5. Third-generation cephalosporins should not be used as single agents for empiric therapy because of risk of the emergence of beta-lactamase-producing bacteria.
- Antibiotic coverage for amebic liver abscesses includes:
  1. Metronidazole 750 mg PO tid for 10 days or tinidazole.
  2. Eradication of the coexistent intestinal infection with paromomycin for 10 days.

CHRONIC Rx

- If fever persists for 2 wk despite percutaneous drainage and antibiotic therapy as outlined under "Acute General Rx," or if there is failure of aspiration or failure of percutaneous drainage, surgery is indicated.
- In patients not responding to intravenous antibiotics and percutaneous drainage, hepatic artery antibiotic infusion can be considered.
- In patients with evidence of metastatic disease that is causing biliary obstruction, a gastroenterology consultation for endoscopic retrograde cholangiopancreatography and stenting should be considered.

DISPOSITION

- Most patients with pyogenic liver abscesses defervesce within 2 wk of treatment with antibiotics and drainage.
- No randomized controlled studies have evaluated the optimal duration of antibiotic therapy for pyogenic liver abscess. Typical duration of antibiotic therapy is at least 4 to 6 wk.
- Pyogenic liver abscess cure rates using percutaneous drainage and antibiotics have been reported to be between 88% and 100%.
- Mortality rate of untreated pyogenic liver abscess is nearly 100%.
- Most patients with amebic liver abscesses defervesce within 4 to 5 days of treatment.
- Amebic liver abscess mortality rate is <1% unless complications occur (see "Comments").
- Follow-up imaging should be used to monitor response to therapy; continue treatment until CT scan shows complete or near-complete resolution of cavity.

REFERRAL

Infectious disease, gastroenterology, interventional radiology, and general surgical consultations are recommended in any patient with hepatic abscess.

PEARLS AND CONSIDERATIONS

COMMENTS

- Complications of pyogenic and amebic liver abscesses include:
  1. Pleuropulmonary extension, resulting in empyema, abscess, and fistula formation
  2. Peritonitis
  3. Purulent pericarditis
  4. Sepsis
- Amebic liver abscesses complicate amebic colitis in nearly 10% of cases.

FIG. E1 **A**, Amebic abscess. Sonogram demonstrates a hypoechogenic mass in the right lobe of the liver with a more hypoechoic surrounding rim. **B**, Computed tomography scan demonstrates a low-attenuation mass in the right lobe of the liver with a prominent halo. (From Kuhn JP et al: *Caffrey's pediatric diagnostic imaging*, vol 2, ed 10, Philadelphia, 2004, Mosby.)

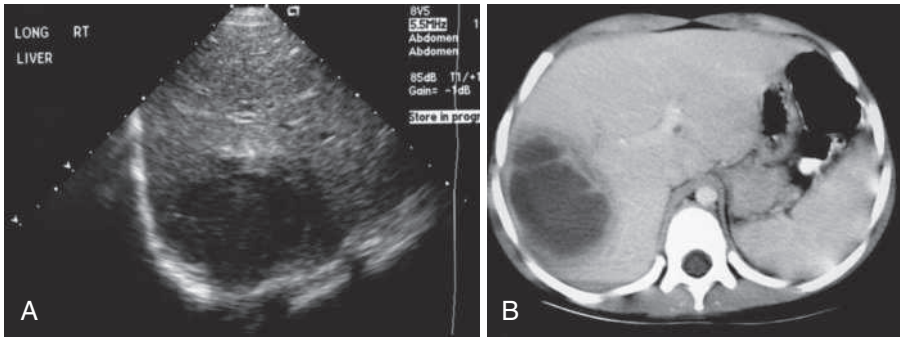

FIG. E2 **Pyogenic liver abscess.** A liver abscess containing *Escherichia coli* has irregular septations and contains a few bubbles of air (*arrows*). Because of the multiple loculations, this abscess did not respond to a percutaneous catheter for drainage and required surgical debridement. (From Webb WR, Brant WE, Major NM: *Fundamentals of body CT*, ed 4, Philadelphia, 2015, Saunders.)

Liver Transplantation

BASIC INFORMATION

DEFINITION

Liver transplantation is surgery to remove a diseased liver and replace it with a donated whole or partial healthy liver. Liver transplantation is a treatment option for acute liver failure, end-stage liver disease, and primary hepatic malignancy. Box E1 summarizes indications for liver transplantation.

ICD-10CM CODE
Z94.4 Liver transplant status

EPIDEMIOLOGY & DEMOGRAPHICS

- Cirrhosis remains the twelfth-leading cause of death for adults in the U.S., with a death rate of 9.2 cases per 100,000 people.
- Accounts for 1.1% of total deaths in the U.S.
- Hepatocellular carcinoma is a primary cancer originating in the liver. Hepatocellular carcinoma is responsible for more than 12,000 deaths a yr in the U.S. and is the highest rising malignancy in the U.S. It is more common in men than women and in those of African descent than whites.

INCIDENCE: Number of patients on liver transplant list exceeds 15,000
PREVALENCE: 6000 liver transplants are performed annually in the U.S.
GENETICS: Genetic factors that may induce end-stage liver failure include hemachromatosis, Wilson disease, alpha-1 antitrypsin deficiency, glycogen storage disease, tyrosinemia

RISK FACTORS

- Viral hepatitis (hepatitis B and C)
- Alcoholic liver disease or Laennec cirrhosis (most common cause of liver transplantation in 2017)
- Nonalcoholic steatohepatitis (NASH)
- Autoimmune liver disease (autoimmune hepatitis, cholestatic liver disease, primary biliary cholangitis, primary sclerosing cholangitis, neonatal sclerosing cholangitis, biliary atresia, Caroli disease, TPN-induced cholestasis)
- Genetics (hemachromatosis, Wilson disease, alpha-1 antitrypsin deficiency, glycogen storage disease, tyrosinemia)
- Vascular liver disease (Budd-Chiari syndrome)
- Hepatocellular carcinoma
- Acute liver failure (drug-induced liver failure [paracetamol/acetaminophen or APAP, non-APAP acute viral hepatitis [acute hepatitis B], Epstein-Barr virus, cytomegalovirus, herpes simplex virus, human immunodeficiency virus) (Box E2)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Cirrhosis alone does not warrant transplantation. Transplantation is considered when a patient presents with manifestations of compromised hepatic function such as portal hypertension or a manifestation of compromised hepatic function. Complications of portal hypertension include esophageal varices, hepatic encephalopathy, ascites, spontaneous bacterial peritonitis, hepatopulmonary syndrome.
- Physical findings and clinical presentation that warrant liver transplantation in patients with end-stage liver disease are recurrent variceal hemorrhage, intractable ascites, spontaneous bacterial peritonitis, refractory encephalopathy, severe jaundice, portal venous thrombosis, worsening hepatic synthetic dysfunction, sudden deterioration, and fulminant hepatic failure.

ETIOLOGY

The etiology of a liver transplant is from end-stage liver disease that has resulted in cirrhosis scarring. The most common are chronic hepatitis C virus (30%), alcoholic cirrhosis (18%), fatty liver disease including NASH, primary liver cancer, acute or chronic hepatitis B virus, bile duct disease, genetic disease, and autoimmune liver disease.

DIFFERENTIAL DIAGNOSIS

Differential diagnosis of acute liver decompensation in patients diagnosed with end-stage liver disease include eclampsia, preeclampsia, and sepsis with multiorgan failure.

WORKUP

- Patients with end-stage liver disease requiring a transplant are accessed by using the MELD-Na score (Model for End-Stage Liver Disease-Na). The MELD-Na score measures the severity of chronic liver disease and can predict mortality within 3 mo of surgery in patients who received a transjugular intrahepatic portosystemic shunt (TIPS) procedure. The score prioritizes who is in need of a transplant as soon as possible.
- MELD-Na score testing includes: Serum bilirubin, serum creatinine, international normalization ratio for prothrombin time, and serum sodium
- MELD-Na = [[3.78 × ln [serum bilirubin (mg/dl)] + 11.2 × ln [INR] + 9.57 × ln [serum creatinine (mg/dl)] + 6.43]] + 1.59 (135-Na)
  1. Maximum and minimum Na of 135 and 120 mmol/L, respectively
- 40 or more: 71.3% mortality
- 30 to 39: 52.6% mortality
- 20 to 29: 19.6% mortality
- 10 to 19: 6.0% mortality (MELD ≥15 warrants liver transplantation workup for waitlist)
- <9: 1.9% mortality

LABORATORY TESTS

MELD score testing: Serum bilirubin, serum creatinine, serum sodium, and the international normalization ratio for prothrombin time.

IMAGING STUDIES

- Abdominal US, CT, or MRI to screen for hepatocellular carcinoma.
- Patients with underlying cirrhosis should be screened for hepatocellular carcinoma with abdominal US every 6 to 12 mo.

TREATMENT

Patients with decompensated liver disease, end-stage liver disease, hepatocellular carcinoma

BOX E1 Indications for Liver Transplantation

- Acute liver failure
- Complications of cirrhosis
  - Ascites
  - Chronic GI blood loss due to portal hypertensive gastropathy
  - Encephalopathy
  - Liver cancer
  - Refractory variceal hemorrhage
  - Synthetic dysfunction
- Liver-based metabolic conditions with systemic manifestations
  - α_1-Antitrypsin deficiency
  - Familial amyloidosis
  - Glycogen storage disease
  - Primary oxaluria
  - Tyrosinemia
  - Urea cycle enzyme deficiencies
  - Wilson disease
- Systemic complications of chronic liver disease
  - Hepatopulmonary syndrome
  - Portopulmonary hypertension

GI, Gastrointestinal.
From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, WB Saunders.

BOX E2 Absolute Contraindications to Liver Transplantation

- AIDS
- Active alcoholism or substance abuse
- Advanced cardiac or pulmonary disease
- Anatomic abnormality that precludes liver transplantation
- Cholangiocarcinoma
- Extrahepatic malignancy
- Fulminant hepatic failure with sustained ICP >50 mm Hg or CPP <40 mm Hg
- Hemangiosarcoma
- Persistent nonadherence
- Uncontrolled sepsis

AIDS, Acquired immune deficiency syndrome; *ICP,* intracranial pressure; *CPP,* cerebral perfusion pressure (CPP = mean arterial pressure minus ICP).
From Feldman M et al [eds]: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, WB Saunders.

within Barcelona with a MELD >15 warrant evaluation at a liver transplant center for further workup and possible registration for the liver transplant waitlist. Allocation for liver transplantation is prioritized by a patient's acuity of illness determined by a patient's MELD-Na score.

LIVING DONOR OR DECEASED DONOR LIVER TRANSPLANTATION

Living donor:

- The scarcity of cadaveric organs has prompted some centers to use living donors, which guarantees transplantation but entails a risk to the donor. Donor compatibility is based on candidates who are family members or close friends of the recipient. The donor must be aged 18 to 60, have compatible blood type with the recipient, be the same physical size or larger, and in excellent health with no history of uncontrolled high blood pressure, liver disease, diabetes, or heart disease. Donor risk includes wound infections, hernia, abdominal bleeding, bile leakage, narrowing of the bile duct, intestinal problems including blockages and tears, organ impairment or failure that leads to the need for transplantation, and death.

Deceased donor:

- Orthotopic liver transplantation is effective for nonresectable early hepatocellular carcinoma, acute liver failure, and end-stage liver disease.

HEPATOCELLULAR CARCINOMA PATIENTS EVALUATED BY THE MILAN AND UCSF CRITERIA

- UCSF criteria: Criteria for liver transplant are as follows: single tumor <6.5 cm, maximum of 3 total tumors with none >4.5 cm, and cumulative tumor size <8 cm, or exceeded UCSF criteria.
- Acute liver failure:
  1. In the case of acute liver failure, the patient is evaluated for liver transplantation based on the "Kings College Criteria," which is based on:
     a. pH <7.3
        OR, in a 24-hour period, all 3 of:
     b. INR >6 (PT >100s) + Cr >300 mmol/L + grade III or IV encephalopathy
  2. Patients who fulfill these criteria and do not have underlying chronic liver disease should be referred to liver transplant centers for urgent evaluation.
- Pretransplant care: Pretransplantation treatment is focused on testing the patients' ability to handle stress of the surgery, immunosuppression, and posttransplantation care. This is achieved by extensive cardiopulmonary evaluation, screening for occult infection or cancer, and psychosocial evaluation. Additional testing includes ABO-Rh blood typing; liver biochemical and function tests (alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, bilirubin, international normalized ratio [INR]); complete blood count with differential; creatinine clearance; serum alpha-fetoprotein; calcium and vitamin D levels; serologies for cytomegalovirus, Epstein-Barr virus, varicella, HIV, hepatitis A, hepatitis B, hepatitis C, rapid plasma regain; urinalysis; and urine drug screen.
- Posttransplant care: The primary goal is to prevent posttransplant rejection of the donated liver. This is accomplished with immunosuppression of the immune system with corticosteroids, calcineurin inhibitors such as tacrolimus (FK-506, Prograf), mycophenolate mofetil (CellCept, Myfortic), mTOR inhibitors (Sirolimus; everolimus), antibodies that remove T cells from the circulation (Thymoglobulin, OKT-3).

REFERRAL

Gastroenterologist and liver transplant team

PROGNOSIS

Average survival rate is 92% after 1 yr and 75% to 85% after 5 yr.

PEARLS & CONSIDERATIONS

COMMENTS

- Cirrhosis alone does not warrant transplantation. Liver transplantation is considered when a patient has suffered either an end-stage liver disease or a manifestation of compromised hepatic function.
- Liver transplantation is always a last option, as the overall determining factor is the number of donor livers available at any time.

PREVENTION

Nongenetic factors such as lifestyle modification and hepatitis B vaccination to avoid developing end-stage liver disease.

PATIENT & FAMILY EDUCATION

Patients who have a genetic predisposition to developing end-stage liver disease from having hemochromatosis, Wilson disease, alpha-1 antitrypsin deficiency, glycogen storage disease, and tyrosinemia would be advised to have genetic screening of immediate family members.

BASIC INFORMATION

DEFINITION

Long QT syndrome (LQTS) is a disorder of myocardial repolarization characterized by a prolongation of the QT interval on the ECG associated with an increased risk of developing life-threatening ventricular arrhythmias, most commonly torsades de pointes (a specific type of polymorphic ventricular tachycardia), which may lead to ventricular fibrillation and sudden cardiac death (SCD). This syndrome may be either genetic or acquired.

SYNONYMS

LQTS
Congenital forms:
Jervell and Lange-Nielsen syndrome (associated with deafness)
Romano-Ward syndrome (associated with normal hearing)

ICD-10CM CODE
I45.81 Long QT syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

- Congenital LQTS is thought to account for >3000 deaths in childhood per yr in the United States.
- Prevalence is felt to be 1:2000 of apparently healthy white young births. It may be higher because this is based on genetic testing of infants in whom the QTc was in excess of 470 and 460 milliseconds, respectively (Schwartz, 2009).
- Presence of LQTS has been shown in all racial groups. Review of data from the US portion of the international LQTS registry found a lower incidence but higher severity of QT prolongation among African Americans.
- Incidence of LQTS is thought to be between 1:2500 and 1:10,000 in the general population, although it has been difficult to estimate due to incomplete penetrance. Congenital form associated with deafness is autosomal recessive (Jervell and Lange Nielsen syndrome) and is less common than the autosomal dominant form as well as more severe.
- Congenital form associated with normal hearing (Romano-Ward syndrome) is autosomal dominant. Although inheritance of LQTS is autosomal dominant, female predominance has often been observed and has been attributed to an increased susceptibility to cardiac arrhythmias in women. LQTS is more likely to express itself before puberty in males and after puberty in females.
- At least 17 different LQTS genes have been identified to date.
- Mortality rate is estimated to be about 1% per yr.
- Multiple mutations causing congenital LQTS have been described. The most common types of LQTS are described in Table 1.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Many episodes are stress mediated.
- Palpitations, presyncope.
- Syncope caused by ventricular tachycardia.
- SCD.
- Seizure.
- Family history of LQTS, but a family history of SCD has not been proved to be a risk factor for SCD in patients with LQTS.
- Abnormal ECG (prolonged QT) in asymptomatic relatives of known case.
- Prolonged QTc interval on ECG (QTc should be >460 ms in women and >440 ms in men). Notably, 20% to 25% genotype positive LQTS may have normal QTc on resting ECG.
- In case of congenital LQTS, the presentation of syncope or SCD is typically triggered by exercise and swimming in LQT1 patients, in LQT2 patients by emotion, pregnancy, or noise, and patients with LQT3 are at highest risk of events when at rest or asleep.

ETIOLOGY

- Cardiac repolarization abnormality
- Congenital cause (hundreds of mutations on more than 10 genes have been identified)
- Most of the gene mutations affect function of ion channels leading to prolonged repolarization (i.e., sodium and potassium channels resulting in either increased Na^+ influx or decreased K^+ efflux). These mutations prolong depolarization and predispose the patient to torsades de pointes
- Acquired causes:
  1. Drugs: Dofetilide, ibutilide, bepridil, quinidine, procainamide, sotalol, amiodarone, ranolazine, disopyramide, phenothiazines and antiemetic agents (droperidol, domperidone), tricyclic antidepressants, antipsychotics (quetiapine, ziprasidone, iloperidone), citalopram, antihistamines, quinolones, azithromycin, astemizole or cisapride given with ketoconazole or erythromycin, clarithromycin, and antimalarials, particularly among patients with asthma or those using potassium-lowering medications; also common in patients receiving methadone
  2. Hypokalemia, hypomagnesemia, hypocalcemia (especially in patients with malabsorption syndrome)
  3. Liquid protein diet
  4. Central nervous system lesions
  5. Ischemia
  6. Hypothyroidism

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- See "Syncope."
- Brugada syndrome, arrhythmogenic right ventricular dysplasia, and LQTS are major causes of genetic sudden death syndromes (Fig. 1).

TABLE 1 Common Types of Long QT (LQT) Syndrome

	LQT1	LQT2	LQT3
Pathophysiology			
Gene	*KCNQ1 (KvLQT1)*	*KCNH2 (HERG)*	*SCN5A*
Protein	$K_v7.1$	$K_v11.1$	$Na_v1.5$
Ionic current	Decreased I_{Ks}	Decreased I_{Kr}	Increased late I_{Na}
Clinical Presentation			
Incidence of cardiac events	63%	46%	18%
Incidence of SCD	4%	4%	4%
Arrhythmia triggers	Emotional/physical stress (swimming, diving)	Emotional stress, arousal (alarm clock, telephone), rest, postpartum period	Sleep/rest
ECG	Broad-based T wave	Low-amplitude, bifid T wave	Long isoelectric ST segment
QT response to exercise	Attenuated QTc shortening and an exaggerated QTc prolongation during early and peak exercise	Normal QT during exercise but with exaggerated QT hysteresis	Supernormal QT shortening
Management			
Exercise restriction	+++	++	?
Response to beta blockers	+++	+++	?
Potassium supplement	+	++	+
Left cervicothoracic sympathectomy	++	++	++
Response to mexiletine	+	+	++

FIG. 1 Sinus rhythm electrocardiogram findings in three genetic sudden death syndromes. A, QT prolongation during sinus rhythm in a patient with long QT syndrome. **B,** ST elevation in V_1 and V_2 in a patient with Brugada syndrome. **C,** T wave inversion in V_1-V_3 in a patient with arrhythmogenic right ventricular dysplasia. (From Goldman L, Schafer AI: *Goldman's Cecil medicine,* ed 24, Philadelphia, 2012, Saunders.)

Diagnostic criteria for the congenital LQTS as per 2013 HRS Guidelines:

LQTS is diagnosed:

- In the presence of an LQTS risk score ≥3.5 in the absence of a secondary cause for QT prolongation and/or
- In the presence of an unequivocally pathogenic mutation in one of the LQTS genes or
- In the presence of a QT interval corrected for heart rate using Bazett formula (QTc) ≥500 ms in repeated 12-lead electrocardiogram (ECG) and in the absence of a secondary cause for QT prolongation
- LQTS can be diagnosed in the presence of a QTc between 480 and 499 ms in repeated 12-lead ECGs in a patient with unexplained syncope in the absence of a secondary cause for QT prolongation and in the absence of a pathogenic mutation

LQTS Risk Score (Schwartz 2011):

ECG Criteria	
QTc >480 ms	3 points
QTc 460-480 ms	2 points
QTc 450-460 ms (males)	1 point
QTc 4th minute of recovery from exercise stress test >480 ms	1 point
Torsade de pointes	2 points
T-wave alternans	1 point
Notched T wave in three leads	1 point
Bradycardia	0.5 point
History	
Syncope with stress	2 points
Syncope without stress	1 point
Congenital deafness	0.5 point
Definite family history of long QT	1 point
Unexplained cardiac death in first-degree relative <30 yr	0.5 point

Total score: 1 point: Low probability of LQTS. 1.5 to 3 points: Intermediate probability of LQTS. ≥ 3.5 points high probability.

WORKUP

Cardiology referral is recommended for all cases.

Genetic analysis is an essential step for risk stratification of patients with congenital prolonged QT and is important for identification of potential mutation carriers within the proband family. There is evidence for gene-specific triggers of events and therapeutic efficacy. Molecular screening should become part of the routine clinical management of LQTS.

In relatives of known patients with LQTS or in young patients with syncope:

- Stress test may prolong the QT interval or cause T-wave alternans.
- Valsalva maneuver: May prolong the QT interval or cause T-wave alternans.
- Prolonged ECG monitoring with various stimulations aimed at increasing catecholamines and assess for QT prolongation (perform in a setting that can provide resuscitation with α- and β-antagonists readily available).
- Epinephrine-induced prolongation of the QT interval (epinephrine infusion QT stress test).
- Genetic analysis:
  1. *LQT1* locus of *KCNQ1* potassium channel gene.
  2. *LQT2* locus of *KCNH2* potassium channel gene.
  3. *LQT3* locus of *SCN5A* sodium channel gene.
  4. These three variants account for >90% of all genotyped LQTS patients, whereas the remaining genes are responsible for a minority of cases.
- Risk stratification for each genetic variant on the basis of gender and QTc: Groups are defined on the basis of the probability of the first cardiac event (syncope, cardiac arrest, or sudden death) before the age of 40 yr or before therapy. Specific mutations, depending on type, location, and degree, may confer a high risk even if the ECG abnormalities are mild. Clinically, QT interval duration was the strongest predictor of risk for cardiac events; a QTc exceeding 500 ms identifies patients with the highest risk.
  1. High risk (>50% of cardiac event): QTc ≥500 ms and LQT1 or LQT2, or male with LQT3.
  2. Moderate risk (30% to 50%): QTc <500 ms in male with LQT3 or in female with LQT2 or LQT3, and female with LQT3 with QTc ≥500 ms.
  3. Low risk (<30%): QTc <500 ms and LQT1 or male LQT2 with QTc <500 ms.
  4. Prophylactic treatment should be considered in all patients with moderate or high risk for cardiac events based on the above risk stratification scheme (Table 2).

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Focuses on exclusion of triggers of life-threatening arrhythmia—there are gene-specific triggers for symptoms:
  1. *LQT1* patients experience 90% of lethal events under physical and emotional stress. Swimming and diving should be avoided or performed under supervision.
  2. *LQT2* patients are at highest risk during arousal or emotions, also during sleep and at rest but not at all during exercise; avoid sudden or excessive acoustic stimuli, especially during sleep (e.g., avoid telephone and/or alarm clock in the proximity)—as opposed to *LQT3* patients, in whom 80% of the events occur at rest or while asleep.
- Previously, all patients with LQTS have been instructed to avoid competitive sports. More recently, low-risk, genetically confirmed LQTS with borderline QTc prolongation, without prior cardiac symptoms and no familial history of SCD are thought to be safe to participate in competitive sports where AED and BLS personnel is available. ICD implantation solely for the purpose of participating in sports is deemed inappropriate. For athletes with ICD implanted for another indication, returning to a low level of exertion is deemed reasonable, and a higher level of exertion may be considered after extensive discussion of potential risks.

TABLE 2 Cardiac Event Risk Stratification Scheme Based on Genes, Gender, and QTc

	QTc <500 ms		QTc ≥550 ms	
Genetic Subtype	**Male**	**Female**	**Male**	**Female**
LQT1	Low	Low	High	High
LQT2	Low	Intermediate	High	High
LQT3	Intermediate	Intermediate	High	Intermediate

Probability of the first cardiac event (syncope, cardiac arrest, or sudden death) before the age of 40 yr or before therapy. High = >50%, Intermediate = 30%-50%, Low = <30%.

TABLE 3 Management of Patients with Long QT Syndrome

Type of Syndrome	Management	Indication
Congenital	Beta-blockers	Asymptomatic patients, symptomatic patients (who do not have bronchospasm)
	Cervicothoracic sympathectomy	Refractory symptoms, especially in pediatric patients
	Cardiac pacing	Refractory symptoms associated with bradycardia, pauses
	Implantable cardioverter-defibrillator	Cardiac arrest, refractory syncope, prophylaxis for moderate- to high-risk patients for cardiac events
Acquired	Elimination of causative drug or condition	All patients
	Magnesium sulfate	Nonsustained ventricular tachycardia, torsades de pointes (even with a normal serum magnesium concentration)
	Administration of potassium (to keep serum K^+ >4.5 mEq/L)	Serum K^+ <4.5 mEq/L
	Maneuvers to increase heart rate (cardiac pacing, isoproterenol)	Bradycardia, arrhythmias refractory to magnesium sulfate

K^+, Potassium.
Adapted from Crawford MH et al [eds]: *Cardiology*, ed 2, St Louis, 2004, Mosby.

- Implantation of an implantable cardioverter-defibrillator (ICD) is recommended according to the ACC/AHA guidelines for patients with a good functional status for more than 1 yr and the following conditions (Table 3):
  1. Survivors of cardiac arrest (class 1).
  2. Patients with syncope or ventricular tachycardia while receiving β-blockers (class IIa).
  3. Prophylaxis of SCD with use of β-blocker in patients with characteristics that suggest high risk (such as *LQT2* and *LQT3, QTc >500 ms*) (class IIb).

PHARMACOLOGIC

- With few exceptions (mostly borderline QTc and LQT1 males aged >25 to 30 yr), all mutation carriers should be treated because of the risk of SCD during first cardiac event. All symptomatic patients should be treated as well.
- Beta-blockers, chiefly propranolol and nadolol, are an initial therapy of choice—there are differential responses to β-blocker therapy among different genetic variants; especially effective among LQT1 patients. Studies showed the efficacy of β-blockers with an overall mortality <2% over a mean follow-up exceeding 5 yr.
- In patients with LQT3, mexiletine shortens the QTc and can be given with a β-blocker for recurrent arrhythmias.
- In the 20% to 30% of patients who continue to have symptoms on a β-blocker, the main options are either left cardiac sympathetic denervation (LCSD) or the prophylactic implantation of an ICD.
- In patients with frequent ICD shocks or in those with high risk for SCD where ICD placement cannot be performed, cardiac pacing and/or LCSD may be indicated.
- In patients with recurrent syncope and/or aborted cardiac arrest despite combined ICD and β-blocker, LCSD as adjunctive therapy can be performed.
- Correctable factors including electrolyte disorder—hypokalemia and hypomagnesemia—and avoidance of precipitating drugs that may further prolong the QT interval is mandatory. A complete list of drugs that can potentially prolong QT may be found at www.crediblemeds.org.
- For patients with acquired form and torsades de pointes, IV magnesium and atrial or ventricular pacing are initial choices.
- Table 3 summarizes management of patients with LQTS.

PROGNOSIS

- In carefully treated patients, mortality is around 0.5% to 1% over 20 yr.
- The timing and frequency of syncope, QTc prolongation, and gender are predictive of risk for aborted cardiac arrest and SCD during adolescence. Higher risk is present in those with one or two or more episodes of syncope in the last 10 yr compared with those with no syncopal episodes, those with QTc >530 ms, and males aged 10 to 12 yr.

PEARLS & CONSIDERATIONS

COMMENTS

- Family history should be assessed for a history of sudden death and other deaths that may have occurred as manifestations of LQTS (e.g., sudden infant death, drowning, and loss of consciousness while driving).
- Propranolol and nadolol are considered superior to metoprolol for prevention of arrhythmias in LQTS.

Lumbar Disk Syndrome

BASIC INFORMATION

DEFINITION

- Lumbar disk syndrome is an all-encompassing term that describes a spectrum of degenerative disk diseases ranging from isolated axial disk pain to disk protrusion and extrusion. Causes are usually secondary to degenerative changes (spondylosis), which can lead to a tear in the annulus fibrosis of a intervertebral disk and allow for the nucleus pulposis (the disk's contents) to herniate. Acute disk herniation (often due to a traumatic event) or gradual arthritic changes of the lumbar spine may lead to nerve root compression that results in lower-extremity pain, sensory changes, or weakness. Massive disk protrusion can sometimes lead to paralysis in the lower extremity, as well as to bowel and bladder dysfunction, a condition termed *cauda equina syndrome.* Cauda equina syndrome is considered a surgical emergency, and the patient must undergo emergent discectomy to relieve the pressure on the nerves.
- Low back pain can also be classified on the basis of symptom duration. Acute back pain is defined as lasting <4 wk, subacute back pain 4 to 12 wk, and chronic back pain lasts >12 wk.

SYNONYMS

Lumbago
Sciatica
Low back pain (LBP)
Radiating leg pain

ICD-10CM CODES	
M51.26	Other intervertebral disc displacement, lumbar region
M48.06	Spinal stenosis, lumbar region
G83.4	Cauda equina syndrome
M47.817	Spondylosis without myelopathy or radiculopathy, lumbosacral region

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- Low back pain is a leading cause of disability worldwide.
- At least one episode in 80% of adults during their lifetime.
- LBP is responsible for more than 3.5 million visits to U.S. emergency departments annually.

PREDOMINANT SEX: Male:female ratio is roughly 2:1

PREDOMINANT AGE: Herniation: 30 to 50 yr

RISK FACTORS: Smoking, obesity, weight-bearing sports (weightlifting, hammer throw), male, family history, and certain work activities that involve repeated lifting. Common degenerative causes of low back pain are summarized in Table E1.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Overlapping clinical syndromes that may result:
  1. Mild herniation without nerve root compression and no leg symptoms
  2. Herniation with nerve root compression and radicular-type leg symptoms
  3. Cauda equina syndrome
  4. Diskitis
  5. Epidural abscess
  6. Chronic degenerative disease with or without leg symptoms
  7. Spinal stenosis
- Presentation and Symptoms:
  1. Low back pain, often worsened by activity or coughing and sneezing
  2. Local lumbar or lumbosacral tenderness
  3. Paresthesias, usually unilateral in the affected nerve's distribution (Fig. E1)
  4. Restricted low back motion
  5. Increased pain on bending toward affected side or flexion
  6. Weakness and reflex changes (L4—knee jerk and quadriceps, L5—extensor hallucis longus, S1—ankle jerk and toe walking) (Table E2)
  7. Sensory examination usually not helpful
  8. Lumbar stenosis can produce symptoms that are often misinterpreted as being vascular (pseudoclaudication). Pseudoclaudication usually recovers quickly with sitting or spine flexion (vascular disease is unaffected by spine position and is typically associated with atrophic skin changes and diminished pulses)
  9. Positive straight leg raising test if nerve root compression is present

ETIOLOGY

Multifactorial: Most commonly trauma and degenerative changes

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Soft tissue strain or sprain
- Tumor
- Stenosis
- Vascular claudication
- Degenerative arthritis of hip
- Insufficiency fracture of hip or pelvis

Section II describes the differential diagnosis of common low back pain syndromes. Red flags for potentially serious underlying causes of low back pain are described in Table E3.

WORKUP

In most cases the diagnosis can be established on a clinical basis alone.

IMAGING STUDIES

- Imaging is not warranted for most patients with acute low back pain. The American College of Physicians guideline for imaging in patients with low back pain recommends initial imaging in patients with major risk factors for cancer, patients with suspected spinal infection, patients with signs of cauda equina syndrome, and patients with severe neurologic deficits.
- Plain roentgenograms may be indicated within the first few weeks for persistent pain; they are usually normal in soft disk herniation, but with chronic degenerative disk disease loss of height of the disk space and osteophyte formation can occur.
- MRI (Fig. E2) may be indicated in patients whose symptoms do not resolve or when other spinal pathology may be suspected.
- Electrodiagnostic studies may confirm the diagnosis or rule out peripheral nerve disorders.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Short course (3 to 5 days) of limited physical activity for acute disk herniation with leg pain.
- Physical therapy for modalities plus a careful gradual exercise program. Physical

TABLE E1 Common Degenerative Causes of Low Back Pain*

	Muscle Strain	Spondylolisthesis	Herniated Disk	Osteoarthritis	Spinal Stenosis
Age (yr)	20-60	20-40	20-60	>40	>50
Pain pattern					
Initial location	Back	Back	Leg > back	Back > leg	Leg > back
Onset	Acute	Insidious	Acute	Insidious	Insidious
Standing	+	+	–	+	+
Sitting	–	–	+	–	–
Flexion	+	–	+	–	–
Extension	–	+	–	+	+
Straight-leg raise	–	–	+	–	–
Plain radiograph	–	+	–	+	+

*+ denotes presence of finding or pain with movement; – denotes absence of finding or pain with movement.
From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.

therapists generally use the McKenzie method.
- Lumbosacral corset brace during rehabilitation process in conjunction with exercise program is beneficial in only a minority of cases.

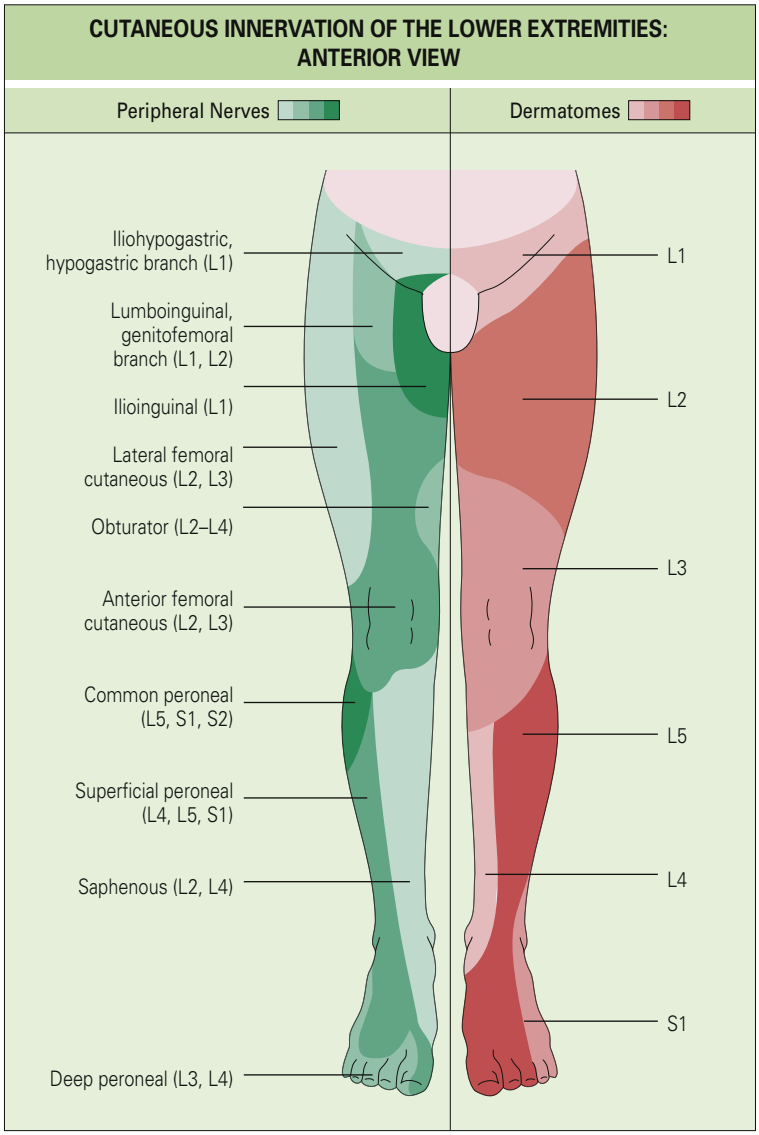

FIG. E1 Cutaneous sensory innervation. Anterior view of the lower extremities illustrating skin areas supplied by nerve roots (*right*) and peripheral nerves (*left*). (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

- Percutaneous electrical nerve stimulation may be beneficial in selected patients with chronic back pain.
- Acupuncture is modestly effective.
- A recent trial of spinal manipulation therapy (SMT) and home exercise with advice (HEA) for subacute and chronic back-related leg pain revealed that SMT plus HEA was more effective than HEA alone after 12 wk, but at 52 wk the benefit was sustained only for global improvement, satisfaction, and medication use and not for self-reported low-back pain, disability, and general health status.

ACUTE GENERAL Rx

- NSAIDs.
- Muscle relaxants for sedative effect are commonly used; however, trials have shown that among patients with acute, nontraumatic, nonradicular LBP presenting to the emergency department, adding cyclobenzaprine or oxycodone/acetaminophen to naproxen alone did not improve functional outcomes or pain at 1-wk follow-up. These findings do not support use of these additional medications in this setting.
- Analgesics provide only modest benefit.
- Injection therapy for low back pain and sciatica has limited clinical benefit and is generally not recommended. Epidural steroid injection for leg symptoms only in selected patients.
- Surgical management can be considered if the symptoms do not improve after conservative treatment. Patients with predominantly radiating leg pain or leg symptoms tend to benefit more from surgery than those with isolated low back pain.

DISPOSITION

- Almost all lumbar disk syndromes improve with time.
- Recurrent episodes usually respond to medical management.
- Recovery from the rare paralytic event is often incomplete.

REFERRAL

- For orthopedic or neurosurgical consultation for intractable pain or significant neurologic deficit
- Emergency referral for cauda equina syndrome
- Table E4 summarizes indications for surgical referral

TABLE E2 Symptoms and Signs of Common Root Compression Syndromes Produced by Lumbar Disk Prolapse

Root Lesion	Pain	Sensory Loss	Motor Weakness	Reflex Lost	Other Signs
S1	From buttock down back of thigh and leg to ankle and foot	Sole of foot and posterior calf	Plantar flexion of ankle and toes	Ankle jerk	Diminished straight leg raising
L5	From buttock to lateral aspect of leg and dorsum of foot	Dorsum of foot and anterolateral aspect of lower leg	Dorsiflexion of foot and toes	None	As above
L4	Lateral aspect of thigh to medial side of calf	Medial aspect of calf and shin	Dorsiflexion and inversion of ankle; extension of knee	Knee jerk	Positive femoral stretch test

From Ballinger A: *Kumar & Clark's essentials of clinical medicine*, ed 6, Edinburgh, 2012, Saunders.

TABLE E3 Red Flags for Potentially Serious Underlying Causes of Low Back Pain

Spinal Fracture
- Significant trauma
- Prolonged glucocorticoid use
- Age >50 yr

Infection or Cancer
- History of cancer
- Unexplained weight loss
- Immunosuppression
- Injection drug use
- Nocturnal pain
- Age >50 yr

Cauda Equina Syndrome
- Urinary retention
- Overflow incontinence
- Fecal incontinence
- Bilateral or progressive motor deficit
- Saddle anesthesia

Spondyloarthritis
- Severe morning stiffness
- Pain improves with exercise, not rest
- Pain during second half of night
- Alternating buttock pain
- Age <40 yr

From Firestein GS et al: *Kelley's textbook of rheumatology,* ed 9, Philadelphia, 2013, Saunders.

FIG. E2 MRI showing a prolapsed L5/S1 disk. (From Carr A, Hamilton W: *Orthopedics in primary care,* ed 2, Philadelphia, 2005, Saunders.)

TABLE E4 Indications for Surgical Referral

Disk Herniation
- Cauda equina syndrome (emergency)
- Serious neurologic deficit
- Progressive neurologic deficit
- Greater than 6 wk of disabling radiculopathy (elective)

Spinal Stenosis
- Serious neurologic deficit
- Progressive neurologic deficit
- Persistent and disabling pseudoclaudication (elective)

Spondylolisthesis
- Serious or progressive neurologic deficit

From Firestein GS et al: *Kelley's textbook of rheumatology*, ed 9, Philadelphia, 2013, Saunders.

PEARLS & CONSIDERATIONS

Red flags suggesting a more serious condition as a cause of the back pain include:
- Fever
- History of malignancy
- Pain at rest
- Incontinence
- Sudden worsening in level of pain
- Weight loss
- Significant motor loss, especially if associated with saddle anesthesia

COMMENTS

- Surgery is most consistently helpful when leg pain (not back pain) predominates.
- No substantial benefit has been shown with oral steroids, traction, epidural corticosteroid injections, or lumbar support.
- Clinicians should only consider opioids in patients who have failed other treatments and only if potential benefits outweigh the risks for individual patients.

BASIC INFORMATION

DEFINITION

A lung abscess is an infection of the lung parenchyma resulting in a necrotic cavity containing pus.

SYNONYM

Pulmonary abscess

ICD-10CM CODES

J85.1	Abscess of lung with pneumonia
J85.2	Abscess of lung without pneumonia
A06.5	Amebic lung abscess

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: Has decreased over the last 30 yr as a result of antibiotic therapy.

- Lung abscess in patients age 50 and over is associated with primary lung neoplasia in 30% of the cases.
- Lung abscesses commonly coexist with empyemas (pus in the pleural space).

RISK FACTORS (SEE TABLE 1):

- Alcohol-related problems
- Seizure disorders
- Cerebrovascular disorders with dysphagia
- Drug abuse
- Esophageal disorders (e.g., scleroderma, esophageal carcinoma)
- Poor oral hygiene
- Obstructive malignant lung disease
- Bronchiectasis

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Symptoms are generally insidious and prolonged, occurring for weeks to months
- Fever, chills, and sweats
- Cough
- Sputum production (purulent with foul odor)
- Pleuritic chest pain
- Hemoptysis
- Dyspnea
- Malaise, fatigue, and weakness
- Tachycardia and tachypnea
- Dullness to percussion, whispered pectoriloquy, and bronchophony
- Amphoric breath sounds (low-pitched sound of air moving across a large open cavity)

ETIOLOGY

- The most important factor predisposing to lung abscess is aspiration.
- Following aspiration as a major predisposing factor is periodontal disease.
- Lung abscess is rare in an edentulous person.
- Approximately 90% of lung abscesses are caused by anaerobic microorganisms (peptostreptococci, microaerophilic streptococci such as *Streptococcus milleri, Bacteroides* species, *Fusobacterium nucleatum, Prevotella*). Pulmonary actinomycosis will also generate lung abscess.
- In most cases anaerobic infection is mixed with aerobic or facultative anaerobic organisms *(S. aureus, E. coli, K. pneumoniae, P. aeruginosa).*
- Parasitic organisms including *Paragonimus westermani* and *Entamoeba histolytica.*
- Fungi including *Aspergillus, Cryptococcus, Histoplasma, Blastomyces,* and *Coccidioides* spp.
- Immunocompromised hosts may become infected with *Aspergillus,* mycobacteria, *Nocardia, Legionella micdadei,* and *Rhodococcus equi.*
- Lung necrosis caused by community strains of Methicillin-resistant *Staphylococcus aureus* (MRSA) (USA 300 strain) in young adults or adolescents after acute influenza was initially reported in 2002 and can be quite fulminant.

DIAGNOSIS

Lung abscess may be primary or secondary.

- *Primary lung abscess* refers to infection from normal host organisms within the lung (e.g., aspiration, pneumonia).
- Secondary lung abscess results from other preexisting conditions (e.g., endocarditis, underlying lung cancer, pulmonary emboli).

Lung abscess may be acute or chronic.

- Acute lung abscess is present if symptoms are of less than 4 to 6 wk.
- Chronic lung abscess is present if symptoms last longer than 6 wk.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis is similar to that for cavitary lung lesions:

- Bacterial (anaerobic, aerobic, infected bulla, empyema, actinomycosis, tuberculosis)
- Fungal (histoplasmosis, coccidioidomycosis, blastomycosis, aspergillosis, cryptococcosis, Zygomycetes)
- Parasitic (amebiasis, echinococcosis)
- Malignancy (primary lung carcinoma, metastatic lung disease, lymphoma, Hodgkin disease)
- Granulomatosis with polyangiitis, sarcoidosis, endocarditis, and septic pulmonary emboli

WORKUP

- The workup of a patient with lung abscess attempts to elicit a primary or a secondary cause.
- Blood tests are not specific in diagnosing lung abscesses.
- Most diagnoses are made from imaging studies; however, to diagnose a specific cause bacteriologic studies are needed.

LABORATORY TESTS

- CBC with leukocytosis
- Bacteriologic studies:
  1. Sputum Gram stain and culture (commonly contaminated by oral flora)
  2. Percutaneous transtracheal aspiration
  3. Percutaneous transthoracic aspiration
  4. Fiberoptic bronchoscopy using bronchial brushings or bronchoalveolar lavage is the most widely used intervention when trying to obtain diagnostic bacteriologic cultures
- Blood cultures on some occasions (<30%) may be positive
- If an empyema is present, obtaining empyema fluid via thoracentesis may isolate the organism

IMAGING STUDIES

- Chest x-ray makes the diagnosis of lung abscess showing the cavitary lesion with an air-fluid level.
- Lung abscesses are most commonly found in the posterior segment of the right upper lobe.
- Chest CT scan can localize and size the lesion and assist in differentiating lung abscesses from other pathologic processes (e.g., tumor, empyema, infected bulla) (Fig. 1).

TREATMENT

NONPHARMACOLOGIC THERAPY

- Oxygen therapy
- Postural drainage
- Respiratory therapy maneuvers

ACUTE GENERAL Rx

- Piperacillin/tazobactam 3.375 g IV q6h in aspiration pneumonia with lung abscess.
- Ceftriaxone 1 to 2 g IV q24h plus metronidazole: 500 mg IV q8h.
- Clindamycin is more effective for anaerobic lung abscess than penicillin alone. Dose: 900 mg IV q8h until improved, then 300 to 600 mg PO q6h.
- Penicillin 1 to 2 million units IV q4h until improvement (afebrile, decreased phlegm production, followed by penicillin VK 500 mg

TABLE 1 Risk Factors for Aspiration Pneumonia and Lung Abscess

Increased bacterial inoculum	Periodontal disease, gingivitis, tonsillar or dental abscess, drugs that decrease gastric acidity
Impairment of consciousness	Drugs, alcohol, general anesthesia, metabolic encephalopathy, coma, shock, cerebrovascular accident, cardiopulmonary arrest, seizures, surgery, trauma
Impairment of cough and gag reflexes	Vocal cord paralysis, intratracheal anesthesia, endotracheal tube, tracheostomy, myopathy, myelopathy, other neurologic disorders
Impairment of esophageal function	Diverticula, achalasia, strictures, disorders of gastrointestinal motility, neoplasm, tracheoesophageal fistula, pseudobulbar palsy
Emesis	Nasogastric tube, gastric dilation, ileus, intestinal obstruction

From Cohen J, Powderly WG: *Infectious diseases*, ed 2, St Louis, 2004, Mosby.

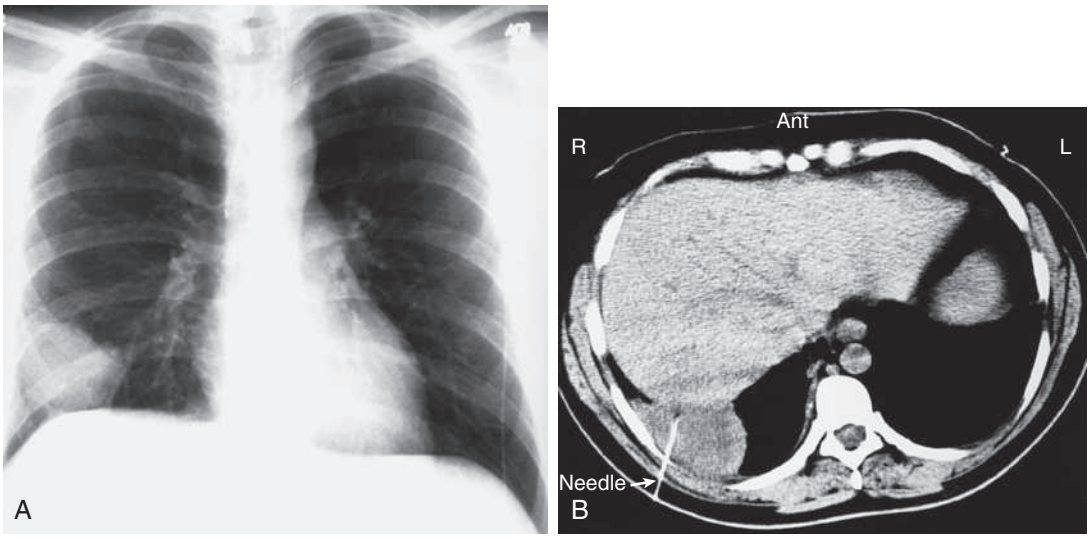

FIG. 1 Lung abscess. On a chest radiograph, a lung abscess may look to be a solid rounded lesion **(A),** or, if it has a connection with the bronchus, there may be an air-fluid level in a thick-walled cavitary lesion. CT scanning **(B)** can be used to localize the lesion and to place a needle for drainage and aspiration of contents for culture. (From Mettler FA [ed]: *Primary care radiology,* Philadelphia, 2000, Saunders.)

PO q6h for 2 to 3 wk but often up to 6 to 8 wk) can be given with metronidazole doses of 7.5 mg/kg IV q6h followed by PO 500 mg bid to qid dosing as an alternative to clindamycin.
- Penicillin should not be used alone because many mouth flora anaerobes now produce penicillinase enzymes. Metronidazole should not be used alone because it is not active against microaerophilic streptococci and some anaerobic cocci.
- Other alternatives are ampicillin/sulbactam and carbapenems such as ertapenem and meropenem.

CHRONIC Rx

- Bronchoscopy to assist with drainage and/or diagnosis is indicated in patients who fail to respond to antibiotics or if there is suspected underlying malignancy.
- Surgery is indicated on rare occasions (<10%) in patients with complications of lung abscess (see "Comments").

DISPOSITION

- More than 95% of patients are cured with the use of antibiotics alone
- Complications of lung abscesses include:
  1. Empyema
  2. Massive hemoptysis
  3. Pneumothorax
  4. Bronchopleural fistula
  5. Hepatobronchial fistula
  6. Brain abscess
  7. Bronchiectasis
- Mortality is low in community-acquired lung abscess (2.5%)
- Hospital-acquired lung abscess carries a high mortality rate (65%)

REFERRAL

If lung abscess is present, consultation with pulmonary and infectious disease specialist is recommended. An interventional radiologist also may be able to perform drainage and obtain cultures.

PEARLS & CONSIDERATIONS

COMMENTS

- Refractory cases are usually the result of:
  1. Large cavity size (>6 cm)
  2. Recurrent aspiration
  3. Thick-walled cavities
  4. Underlying lung carcinoma
  5. Empyema formation
- Necrotizing pneumonia is similar to a lung abscess but differs in size (<2 cm in diameter) and number (usually multiple suppurative cavitary lesions)

BASIC INFORMATION

DEFINITION

A primary lung neoplasm is a malignancy arising from lung tissue. The different types are non–small cell lung cancer (NSCLC, 85% of all lung cancers; squamous cell carcinoma, adenocarcinoma, and large cell carcinoma) and small cell lung cancer (SCLC, 15% of all lung cancers).

ADENOCARCINOMA: Represents 35% to 40% of lung carcinomas; frequently located in midlung and periphery; initial metastases are to lymphatics; frequently associated with peripheral scars; adenocarcinoma is described as preinvasive, minimally invasive, or invasive.

SQUAMOUS CELL: Represents 20% to 30% of lung cancers; central location; metastasis by local invasion; frequent cavitation and obstructive phenomena.

SMALL CELL: Represents 15% of lung carcinomas; central location; metastasis through lymphatics; associated with lesion of the short arm of chromosome 3; high cavitation rate.

LARGE CELL: Represents 10% to 15% of lung carcinomas; frequently located in the periphery; metastasis to central nervous system and mediastinum; rapid growth rate with early metastasis.

LEPIDIC-PREDOMINANT PATTERN (BRONCHOALVEOLAR): Represents 5% of lung carcinomas; frequently located in the periphery; may be bilateral; initial metastasis through lymphatic, hematogenous, and local invasion; no correlation with cigarette smoking; cavitation rare.

SYNONYM

Lung cancer

ICD-10CM CODES

C34.10	Malignant neoplasm of upper lobe, unspecified bronchus or lung
C34.11	Malignant neoplasm of upper lobe, right bronchus or lung
C34.12	Malignant neoplasm of upper lobe, left bronchus or lung
C34.2	Malignant neoplasm of middle lobe, bronchus or lung
C34.30	Malignant neoplasm of lower lobe, unspecified bronchus or lung
C34.31	Malignant neoplasm of lower lobe, right bronchus or lung
C34.32	Malignant neoplasm of lower lobe, left bronchus or lung
C34.80	Malignant neoplasm of overlapping sites of unspecified bronchus and lung
C34.81	Malignant neoplasm of overlapping sites of right bronchus and lung
C34.82	Malignant neoplasm of overlapping sites of left bronchus and lung
C34.90	Malignant neoplasm of unspecified part of unspecified bronchus or lung
C34.91	Malignant neoplasm of unspecified part of right bronchus or lung
C34.92	Malignant neoplasm of unspecified part of left bronchus or lung

EPIDEMIOLOGY & DEMOGRAPHICS

- Lung cancer is responsible for >30% of cancer deaths in males and >25% of cancer deaths in females. It has been the most common cancer in the world since 1985 and is the leading cause of cancer-related death in both sexes.
- Tobacco smoke is implicated in 90% of cases; of these, secondhand smoke is responsible for approximately 20% of cases.
- In the U.S., there were an estimated 228,150 new cases of lung cancer and 142,670 deaths from lung cancer in 2019. Worldwide 1.6 million tumor-related deaths are attributed annually to lung cancer.
- From 1990 through 2013 the percentage of patients with non–small cell lung cancer who never smoked rose from 8% to 16%, raising concerns about environmental carcinogens.
- Coincident with the decrease in smoking rates, the incidence of new cases and the rate lung cancer deaths in the U.S. continue to decrease. However, death rates among African Americans continue to be disproportionately higher.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Weight loss, fatigue, fever, anorexia, dysphagia
- Cough, hemoptysis, dyspnea, wheezing
- Chest, shoulder, and bone pain
- Paraneoplastic syndromes (see Table 1):
  1. Lambert-Eaton myasthenic syndrome: Myopathy involving proximal muscle groups
  2. Endocrine manifestations: Hypercalcemia, ectopic adrenocorticotropic hormone secretion, syndrome of inappropriate excretion of adrenocorticotropic hormone (SIADH)
  3. Neurologic: Subacute cerebellar degeneration, peripheral neuropathy, cortical degeneration
  4. Musculoskeletal: Polymyositis, clubbing, hypertrophic pulmonary osteoarthropathy
  5. Hematologic or vascular: Migratory thrombophlebitis, marantic thrombosis, anemia, thrombocytosis, or thrombocytopenia
  6. Cutaneous: Acanthosis nigricans, dermatomyositis
- Pleural effusion (10% of patients), recurrent pneumonias (from obstruction), localized wheezing
- *Superior vena cava syndrome:*
  1. Obstruction of venous return of the superior vena cava is most commonly caused by bronchogenic carcinoma or metastasis to paratracheal nodes
  2. The patient usually reports headache, nausea, dizziness, visual changes, syncope, and respiratory distress
  3. Physical examination reveals distention of thoracic and neck veins, edema of face and upper extremities, facial plethora, and cyanosis
- *Horner syndrome:* Constricted pupil, ptosis, facial anhidrosis caused by spinal cord damage between C8 and T1 as a result of a superior sulcus tumor (bronchogenic carcinoma of the extreme lung apex)
- *Pancoast tumor:* A superior sulcus tumor (Fig. 1) associated with ipsilateral Horner syndrome and shoulder pain

ETIOLOGY

- Tobacco abuse: The molecular pathology of smoking-related lung cancer is illustrated in Fig. E2. The chance of developing lung cancer for a 40-pack-yr persistent smoker is 20 times that of someone who never smoked.
- Environmental agents (e.g., radon) and industrial agents (e.g., ionizing radiation, asbestos, nickel, uranium, vinyl chloride, chromium, arsenic, coal dust).
- Lung cancer susceptibility and risk increased in inherited cancer syndromes caused by germline mutations in p53, retinoblastoma, and epidermal growth factor receptor *(EGFR)* genes.
- Fig. E3 illustrates the multistep cellular carcinogenesis in lung cancer.

TABLE 1 Paraneoplastic Syndromes Associated with Bronchogenic Carcinoma

Syndrome	Cell Type	Mechanism
Hypertrophic pulmonary osteoarthropathy and clubbing	All types	Unknown
Hyponatremia	SCLC most common; may be any type	SIADH, ectopic antidiuretic hormone production by tumor
Hypercalcemia	Usually squamous cell	Bone metastases, osteoclast-activating factor, parathyroid hormone–like hormone, prostaglandins
Cushing syndrome	Usually SCLC	Ectopic ACTH production
Lambert-Eaton myasthenic syndrome	Usually SCLC	Voltage-sensitive calcium channel antibodies in >75%; affects presynaptic neuronal calcium channel activity
Other neuromyopathic disorders	SCLC most common; may be any type	Antineuronal nuclear antibodies, also known as anti-Hu; others unknown
Thrombophlebitis	All types	Unknown

ACTH, Adrenocorticotropic hormone; *SCLC,* small cell lung cancer; *SIADH,* syndrome of inappropriate secretion of antidiuretic hormone.

Adapted from Andreoli TE et al: *Andreoli and Carpenter's Cecil essentials of medicine,* ed 8, Philadelphia, 2010, Saunders.

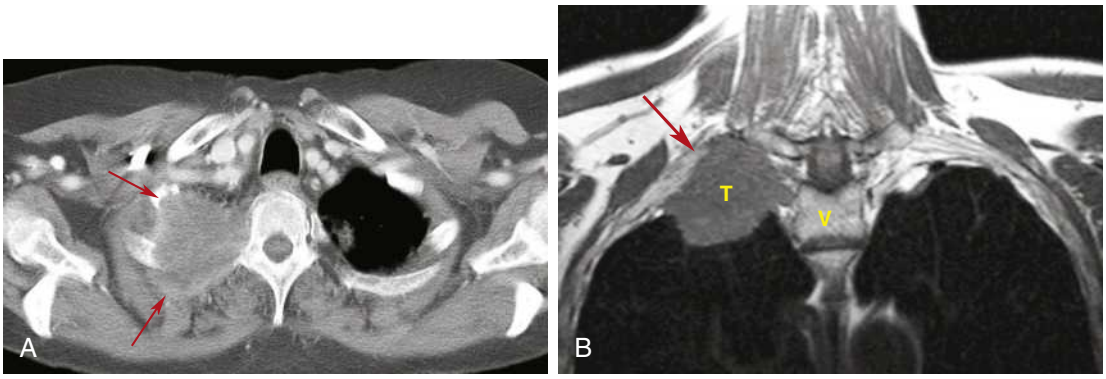

FIG. 1 Pancoast tumor with chest wall invasion. A, On computed tomography, a right apical mass is associated with invasion of the chest wall and rib destruction *(arrows)* . Although the tumor appears to contact the vertebral body, it appears intact. **B,** Coronal magnetic resonance imaging shows the relationship of the tumor (*T*) to the vertebral body (*V*) and the brachial plexus (*arrow*), which appears to be involved. (From Webb WR et al: *Fundamentals of body CT*, ed 4, Philadelphia, 2015, Elsevier.)

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Pneumonia
- Tuberculosis (TB)
- Metastatic carcinoma to the lung
- Lung abscess
- Granulomatous disease
- Carcinoid tumor
- Sarcoidosis
- Benign lesions that simulate thoracic malignancy:
  1. Lobar atelectasis: Pneumonia, chronic inflammatory disease, allergic bronchopulmonary aspergillosis
  2. Multiple pulmonary nodules: Septic emboli, Wegener granulomatosis, sarcoidosis, rheumatoid nodules, fungal disease, multiple pulmonary atrioventricular fistulas
  3. Mediastinal adenopathy: Sarcoidosis, lymphoma, primary TB, fungal disease, silicosis, pneumoconiosis, drug-induced (e.g., phenytoin, trimethadione)
  4. Pleural effusion: Congestive heart failure, pneumonia with parapneumonic effusion, TB, viral pneumonitis, ascites, pancreatitis, collagen-vascular disease

WORKUP

- The workup generally includes chest CT, positron-emission tomographic (PET) scan, and tissue biopsy. Molecular testing for treatable oncogenic alterations should be performed to further classify NSCLC. This includes testing for mutations in the gene encoding epidermal growth factor receptor (eGFR) and in BRAF v600e, searching for translocations in the genes encoding anaplastic lymphoma kinase (ALK) and rat osteosarcoma (ROS1), and assessing expression of programmed death-ligand-1 (PD-L1).[1] Common immunohistochemical markers used in the diagnosis of lung tumors are summarized in Table 2. Table 3 describes common molecular alterations in lung tumors.
- Additional lab tests include CBC, serum chemistry studies.
- Diagnosis and staging of lung cancer should be performed simultaneously to minimize invasive testing.

LABORATORY TESTS

Various modalities are available to obtain a tissue diagnosis:

- Biopsy of any suspicious lymph nodes (e.g., supraclavicular or mediastinal node)
- Flexible fiberoptic bronchoscopy: Brush and biopsy specimens are obtained from any visualized endobronchial lesions. The use of a gene-expression classifier has a high sensitivity across different lesion sizes, locations, stages, and cell type of lung cancer. The combination of the classifier plus bronchoscopy has a sensitivity of >85%. In intermediate-risk patients with a nondiagnostic bronchoscopic examination, a negative classifier score provides support for a more conservative diagnostic approach[2]
- Transbronchial needle aspiration: Done with a special needle passed through the bronchoscope; this technique is useful to sample mediastinal masses or paratracheal lymph nodes
- Transthoracic fine-needle aspiration biopsy with fluoroscopic or CT scan guidance to evaluate peripheral pulmonary nodules
- Endobronchial ultrasound (EBUS) guided biopsy and staging is now routinely used to evaluate suspected mediastinal and hilar nodes
- Mediastinoscopy and anteromedial sternotomy in suspected tumor involvement of the mediastinum
- Pleural biopsy in patients with pleural effusion
- Thoracentesis of pleural effusion and cytologic evaluation of the obtained fluid may confirm diagnosis

IMAGING STUDIES

- Chest x-ray (Fig. 4): The radiographic presentation often varies with the cell type. Presence of pleural effusion, lobar atelectasis, and mediastinal adenopathy can occur in any cell type.
- CT scan of the chest (Fig. 5) can evaluate mediastinal and pleural extension. The chest CT should include liver and adrenal glands (common sites of metastases). CT or MRI of brain should be considered in a patient presenting with neurologic symptoms (e.g., headaches, vision disturbances).
- PET with ^{18}F-fluorodeoxyglucose (^{18}FDG-PET) (Fig. E6) is superior to CT in detecting mediastinal and distant metastases in NSCLC. It is useful for preoperative staging of NSCLC.
- The use of PET-CT (Fig. E7) for preoperative staging of NSCLC reduces both the total number of thoracotomies and the number of futile thoracotomies.

STAGING

After confirmation of diagnosis, patients should undergo staging:

- In NSCLC, the TNM staging system is used. Table 4 summarizes TNM stage groups. Both stage I (no lymph node involvement) and stage II (ipsilateral bronchopulmonary/ hilar lymph nodes or T_3 tumor) include localized tumors for which surgical resection is the preferred treatment. Stage III is subdivided into III_A (potentially resectable) and II_B/III_C (unresectable). Stage IV indicates metastatic disease with stage IV_A referring to intrathoracic metastases or pleural involvement or single extra-thoracic metastasis. stage IV_B includes tumors with multiple extra-thoracic metastases
- In SCLC, the staging system developed by the Veterans Administration Lung Cancer Study Group is used. It contains two stages:
  1. Limited-stage disease: Confined to the regional lymph nodes and to one hemithorax (excluding pleural surfaces), which can be included in a single radiation portal

TABLE 2 Common Immunohistochemical Markers Used in the Diagnosis of Lung Tumors

Diagnosis	Positive Immunohistochemical Markers
Squamous cell carcinoma	Cytokeratin (CK) cocktail (e.g., AE1/AE3)
	p63
	p40
	CK5/6
	CK7 in up to 30%
Adenocarcinoma including adenocarcinoma in situ or minimally invasive adenocarcinoma, nonmucinous	CK cocktail
	CK7
	TTF-1
	Napsin A
In situ and invasive mucinous adenocarcinoma	CK cocktail
	CK7
	CK20
	cdx-2
	TTF-1 rare
Large cell neuroendocrine carcinoma	CK cocktail
	TTF-1
	CD56
	Chromogranin A
	Synaptophysin
Carcinoid tumor	CK cocktail
	TTF-1 (weaker than in high-grade neuroendocrine tumors)
	CD56
	Chromogranin A
	Synaptophysin
Atypical carcinoid tumor	CK cocktail (tends to be patchy)
	TTF-1 (weaker than in high-grade neuroendocrine tumors)
	CD56
	Chromogranin A
	Synaptophysin
Common differential diagnoses:	
• Colonic adenocarcinoma	CK20+/CK7–
• Lung, breast, pancreatobiliary, upper gastrointestinal adenocarcinoma	CK7+/CK20–
• Urothelial carcinoma	CK7+/CK20+
• Prostatic adenocarcinoma	CK7–/CK20–
• Mesothelioma	Calretinin, WT1, CK5/6
• Malignant melanoma	S-100, HMB-45, Melan-A

From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

2. Extensive-stage disease: Spread beyond the confines of limited-stage disease

- Pretreatment staging procedures for lung cancer patients, in addition to complete history and physical examination, generally include the following tests:
  1. Chest radiograph (posteroanterior and lateral), ECG
  2. Laboratory evaluation: Complete blood count, complete metabolic panel; arterial blood gases and pulse oximetry in selected cases
  3. Pulmonary function studies
  4. CT scan of chest and PET scan: Trials have shown a reduction in futile thoracotomies for patients with suspected NSCLC who undergo preoperative assessment with PET in addition to conventional workup
  5. Mediastinoscopy or anterior mediastinotomy in patients being considered for possible curative lung resection
  6. Biopsy of any accessible suspect lesions
  7. CT scan to include liver and brain
  8. Bone marrow aspiration and biopsy only in selected patients with small cell carcinoma of the lung. In the absence of an increased lactate dehydrogenase or cytopenias, routine bone marrow examination is not recommended
  9. Newer technologies in preoperative staging include endoscopic bronchial ultrasonography and esophageal ultrasonography to guide biopsies; however, cervical mediastinoscopy is standard criterion in preoperative nodal staging (sensitivity >93%, specificity >95%)

TABLE 3 Examples of Common Molecular Alterations in Lung Tumors

Diagnosis	Common Molecular Alterations
Squamous preneoplasia	LOH—3p, 9p21, 8p21–23, aneuploidy, methylation
Atypical adenomatous hyperplasia	LOH—3p, 9p, aneuploidy
	K-ras codon 12 mutation
Adenocarcinoma	p53 mutation
	p16 mutation/inactivation
	K-Ras (42%); smokers more common
	EGFR overexpression (40%)
	EGFR mutation
	Her2/neu, COX-2 overexpression
Squamous cell carcinoma	p53 mutation
	p16 inactivation
	Allelic loss 3p
	EGFR overexpression (80%)
Large cell carcinoma	K-Ras, p53, loss p16
Large cell neuroendocrine carcinoma	p53
	bcl-2 overexpression
	Rb mutation
	3p21, FHIT, 3p22–24, 5q21,9p21
Small cell carcinoma	Rb mutation (80+%)
	p53 mutation 50%–80%
	BCL-2 expression
	3p21, FHIT, 3p22–24, 5q21,9p21

COX-2, Cyclooxygenase 2; *EGFR,* epidermal growth factor receptor; *LOH,* loss of heterozygosity.
From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- Nutritional support
- Avoidance of tobacco and other substances toxic to the lungs
- Supplemental oxygen

ACUTE GENERAL Rx

NON–SMALL CELL CARCINOMA:

- Surgical resection is standard in patients with operable NSCLC (stage I or II) who are surgical candidates. Lobectomy is the best standard surgical approach. Lesser resections may be necessary in patients with marginal pulmonary reserve. Video-assisted thoracic surgery (VATS) decreases morbidity and shortens the hospital stay.
  1. Surgical resection is indicated in patients with limited disease (not involving mediastinal nodes, ribs, pleura, or distant sites). This represents approximately 15% to 30% of diagnosed cases. Stereotactic ablative radiotherapy is a

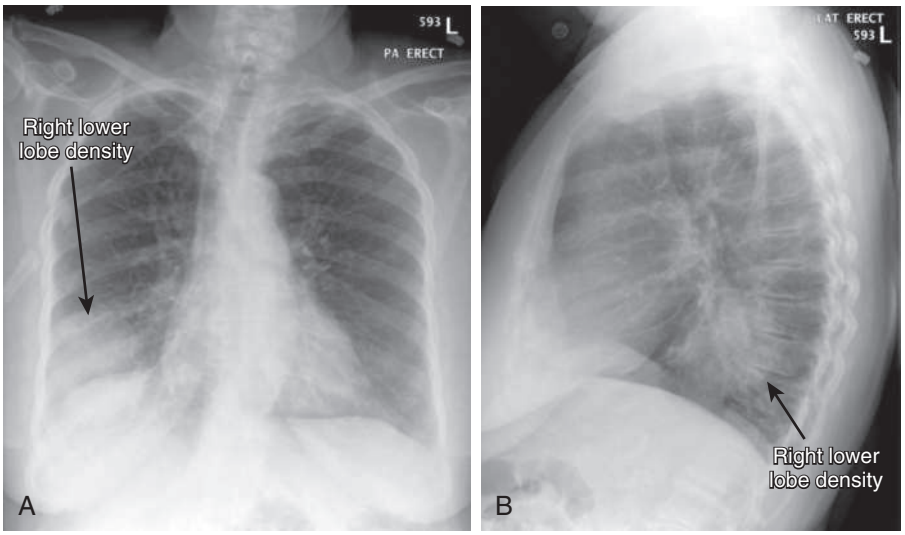

FIG. 4 Lung neoplasm, primary. Lung mass presenting with hemoptysis. **A,** Posterior-anterior (PA) chest x-ray. **B,** Lateral chest x-ray. This 83-yr-old female presented with hemoptysis of a quarter-sized clot. Her posterior-anterior chest x-ray shows a rounded right lower lobe density. On the lateral view, this is visible in the retrocardiac space. This density measures 7.6 cm in diameter. Pneumonia, neoplasm, or abscess could have this appearance on chest x-ray. Computed tomography was performed to further delineate the pathology (see Fig. 5). (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

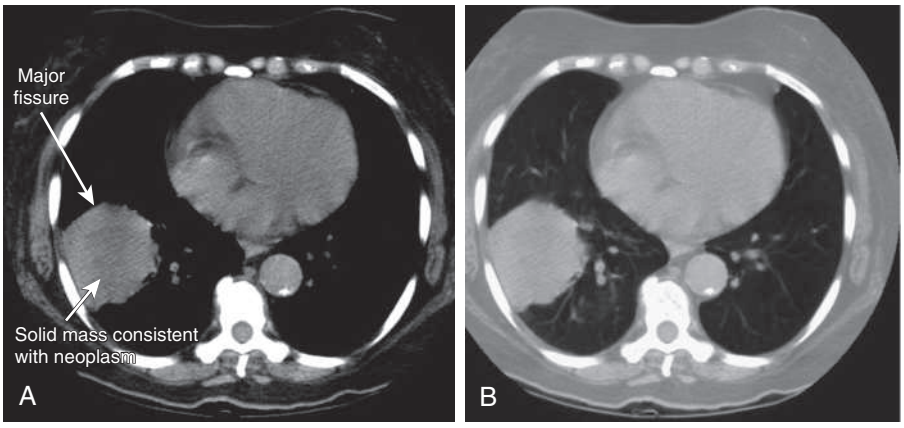

FIG. 5 Lung neoplasm, primary. Lung mass presenting with hemoptysis. Same patient as in Fig. 4. Noncontrast computed tomography was performed (contrast was withheld as a consequence of the patient's renal dysfunction) and shows a 6 by 6 cm round lesion abutting the oblique fissure (also called the major fissure) and lateral chest wall. **A,** Soft tissue windows. **B,** Lung windows. On soft tissue windows, the center appears slightly darker, indicating lower density that may represent central necrosis. If IV contrast had been given, an area of necrosis would have failed to enhance. Infection or infarction is technically possible, but a pulmonary neoplasm is the most likely explanation for this lesion. Biopsy showed this to be a moderately differentiated squamous cell carcinoma. (From Broder JS: *Diagnostic imaging for the emergency physician,* Philadelphia, 2011, Saunders.)

reasonable option for patients with localized NSCLC who are not surgical candidates. Multimodality treatment guidelines are summarized in Table 5.

2. Preoperative evaluation includes cardiac status and pulmonary function assessment. Pneumonectomy is possible if the patient has a preoperative FEV_1 = 2 L or if the maximal voluntary ventilation is >50% of predicted capacity. Individuals with FEV_1 >1.5 L are suitable for lobectomy without further evaluation unless there is evidence of interstitial lung disease or undue dyspnea on exertion. In that case, carbon dioxide diffusion in the lung (DLCO) should be measured. If the DLCO is <80% predicted normal, the individual may not be clearly operable.
3. Conventional radiotherapy fails to durably control the primary lung tumor in nearly 70% of patients and 2-yr survival is less than 40%. Stereotactic body radiation (SBRT) uses several highly focused radiation beams to deliver total higher doses of radiotherapy (in high doses in 3 to 5 fractions) and is more effective than conventional radiotherapy, with a local control rate equivalent to that with surgery in inoperable early stage lung cancer.
4. Preoperative chemotherapy should be considered in patients with more advanced disease (stage IIIA) who are being considered for surgery because it increases the median survival time in patients with NSCLC compared with surgery alone.
5. Postoperative adjuvant chemotherapy with doublet regimens significantly increases 5-yr survival (69% vs. 54%) in patients with completely resected stage II-IIIA NSCLC. For stage I NSCLC there may be some patients who benefit from adjuvant chemotherapy. An algorithm for selecting patients with stage I NSCLC for postoperative adjuvant chemotherapy is outlined in Fig. 8.

- Treatment of unresectable NSCLC:
  1. Radiotherapy alone is used primarily for treatment of central nervous system and skeletal metastases, superior vena cava syndrome. Thoracic radiotherapy in combination with chemotherapy is standard therapy for unresectable stage 3 disease.
  2. Chemotherapy, targeted therapy, and immune checkpoint therapy are the mainstays of treatment for advanced stage IV or metastatic NSCLC. Initial stratification is done based on pathology (squamous vs. nonsquamous cancers), presence of driver mutations (e.g., *EGFR, ALK, ROS1,* and *BRAF* mutations in adenocarcinomas), and expression of programmed death receptor ligand-1 (PDL-1). Table 6 summarizes selected NSCLC oncogenes and targeted therapy.
  3. A platinum-based chemotherapy doublet regimen is recommended for fit patients, and single agents are offered to elderly patients and those with poor performance status. Various combination regimens are available with platinum plus pemetrexed preferred for nonsquamous cancers while other for squamous cancers other doublets such as paclitaxel plus carboplatin, cisplatin plus vinorelbine, gemcitabine plus cisplatin, and cisplatin plus docetaxel are utilized with none being clearly superior to the others. The addition of bevacizumab to paclitaxel plus carboplatin results in significant survival benefit in nonsquamous cancers.
  4. Upfront therapy with pembrolizumab, a PD-1 immune-checkpoint inhibitor antibody that disrupts PD-1 mediated signaling and restores antitumor immunity, is superior to chemotherapy in patients with >50% PD-L1 expression. When pembrolizumab is combined with chemotherapy in patients with 1-50% PD-L1 expression, there is an improvement in overall survival. In addition, atezolizumab and nivolumab (other checkpoint inhibitors) have been shown to have superior survival benefit versus docetaxel in advanced NSCLC that had previously received chemotherapy.

5. Tyrosine kinase inhibitors targeting activating mutations are of use in patients whose adenocarcinomas harbor the EGFR mutations, which are more commonly detected in patients who never smoked or are light smokers and in Asian patients. Gefitinib, erlotinib, afatinib, osimertinib, and dacomitinib are oral EGFR inhibitors that have showed impressive responses and improvements in median overall survival to the range of 30 mo. Currently, first-line therapy with the oral inhibitor osimertinib is the preferred option based on updated data demonstrating median overall survival of 36 mo.
6. Oncogenic fusion genes consisting of *EML4* and anaplastic lymphoma kinase (ALK) are present in 4% to 5% of adenocarcinomas and can be treated with inhibitors crizotinib, ceritinib, alectinib, brigatinib, or lorlatinib. Approximately 2% of adenocarcinomas have genetic rearrangements involving the ROS1 proto-oncogenic receptor tyrosine kinase (ROS1), and these patients can be treated with the oral inhibitors crizotinib and ceritinib. Also, approximately 2% of adenocarcinomas harbor the BRAF V600E mutation, and these patients can be treated with the combination of BRAF inhibitor and MEK inhibitor therapy.
7. The addition of chemotherapy to radiotherapy (CRT) improves survival in patients with locally advanced, unresectable stages III NSCLC. The addition of the checkpoint inhibitor durvalumab has recently shown improvement in overall survival in this population when administered sequentially after CRT.
8. Early initiation of palliative care focusing on management of symptoms, psychosocial support, and assistance with decision making in patients with metastatic NSCLC leads to improved quality of life, longer survival, and less use of aggressive end-of-life care.

TABLE 4 TNM Stage Groups for Non–Small Cell Lung Cancer

Stage	T	N	M
Stage 0	T_{is}	N_0	M_0
Stage I_{A1}	T_{mi} or T_{1a}	N_0	M_0
Stage I_{A2}	T_{1b}	N_0	M_0
Stage I_{A3}	T_{1c}	N_0	M_0
Stage I_B	T_{2a}	N_0	M_0
Stage II_A	T_{2b}	N_0	M_0
Stage II_B	T_{1a-c}	N_1	M_0

Stage IV_A	Any T	Any N	M_{1a-1b}
Stage IV_B	Any T	Any N	M_{1c}

TNM, Tumor, node, metastases.

SMALL CELL LUNG CANCER:

- Limited-stage disease: Standard treatments include thoracic radiotherapy and chemotherapy (cisplatin and etoposide).
- Extensive-stage disease: Standard treatments include combination chemotherapy (platinum plus etoposide or platinum plus irinotecan). The addition of the PD-1 antibody atezolizumab to standard first-line therapy has now been proven to improve overall survival and is considered the standard of care approach.
- Prophylactic cranial irradiation for patients in complete remission to decrease the risk of central nervous system metastasis.
- Despite high initial response rates, most patients eventually relapse. Topotecan or irinotecan may be an option for these patients. The anti-PD-1 antibody, nivolumab, has demonstrated survival benefit in SCLC patients who have failed standard therapies.

DISPOSITION

- The 5-yr survival of patients with NSCLC when the disease is resectable is approximately 30%. The 5-yr survival for stage 4 patients is now increasing, with long-term survivors seen after immunotherapy use and survival rates >20% reported in current trials.
- Median survival time in patients with limited-stage disease SCLC is 15 mo; in patients with extensive-stage SCLC, it is 9 mo.
- Among patients with metastatic NSCLC, early palliative care results in longer survival and significant improvements in both quality of life and mood.

PEARLS & CONSIDERATIONS

CT screening with use of low-dose computed tomography (LDCT) for detection of lung cancer among persons with a heavy history of smoking increases the percentage of lung cancer cases that are diagnosed in stage 1 and reduces mortality from lung cancer. The National Lung Screening Trial (NLST) showed that lung cancer screening with LDCT resulted in a 20% reduction in lung cancer mortality. New guidelines recommend annual LDCT for those who are current or former smokers aged 55 to 74. Screening should be discontinued once a person has not smoked for 15 yr or develops a health problem that substantially limits life expectancy or the ability or willingness to have curative lung surgery.

TABLE 6 Selected Non–Small Cell Lung Cancer Oncogenes and Targeted Therapy

Oncogene Alteration	Incidence (%)	Clinical Relevance	Treatment
BRAF			
Mutation	1-3	V600E mutation: Most common, equal association with smokers and nonsmokers May be mechanism of acquired EGFR TKI resistance	dabrafenib plus trametinib
EGFR (ErbB1, HER1)			
Mutation	13-50	Exon 19 deletion and Exon 21 point mutation are the most common Predominantly adenocarcinoma and nonsmokers; up to 50% frequency in Asians	TKI: Gefitinib, erlotinib, afatinib, osimertinib
EML4-ALK			
Fusion	3-7	Most frequent in adenocarcinomas, nonsmokers, men, and younger patients	Nonspecific TKI: Crizotinib, ceritinib, alectinib, brigatinib
Her2/neu (ErbB2)			No approved therapy
Mutation	2-6	Mostly adenocarcinomas and nonsmokers	
Amplification	23	Mechanism of resistance to EGFR TKI	
KRAS			
Mutation	5-30	Mostly adenocarcinomas and smokers May contribute to resistance to ALF, BRAF, and PI3K inhibitors	No approved therapy
MET			No approved therapy
Mutation	<5		
Amplification	21	Mechanism of resistance to EGFR TKI	
PIK3CA			No approved therapy
Mutation	<10	Frequently occurs in association with other mutations; more common in squamous cell	
Amplification	5-43	Mechanism of resistance to EGFR TKI	
PTEN			
Mutation	1.7-10	Associated with PI3K activation, resistance to EGFR TKI, and sensitivity to PI3K inhibitors More frequent in squamous cell	
Loss of function	4-21	Associated with PI3K activation, resistance to EGFR TKI, and sensitivity to PI3K inhibitors More frequent in squamous cell	
RET fusion gene	1-2	Mostly adenocarcinomas and nonsmokers	No approved therapy
ROS1 fusion gene	2	Mostly adenocarcinomas, nonsmokers, and younger patients	TKI: Crizotinib
VEGF			Monoclonal antibodies: Bevacizumab VEGFR TKI

BRAF, v-raf murine sarcoma viral oncogene homolog B1; *EGFR,* epidermal growth factor receptor; *EML4-ALK,* echinoderm microtubule-associated protein-like 4 anaplastic lymphoma kinase; *ERBB,* avian erythroblastosis oncogene B; *Her2,* human epidermal growth factor receptor 2; *KRAS,* Kirsten Rat sarcoma viral oncogene homolog; *MET,* mesenchymal-epithelial transition; *PIK3CA,* phosphoinositide-3-kinase catalytic alpha polypeptide; *PTEN,* phosphatase and tensin homolog; *RET,* rearranged during transfection; *ROS1,* reactive oxygen species 1; *TKI,* tyrosine kinase inhibitor; *VEGF,* vascular endothelial growth factor; *VEGFR,* vascular endothelial growth factor receptor.

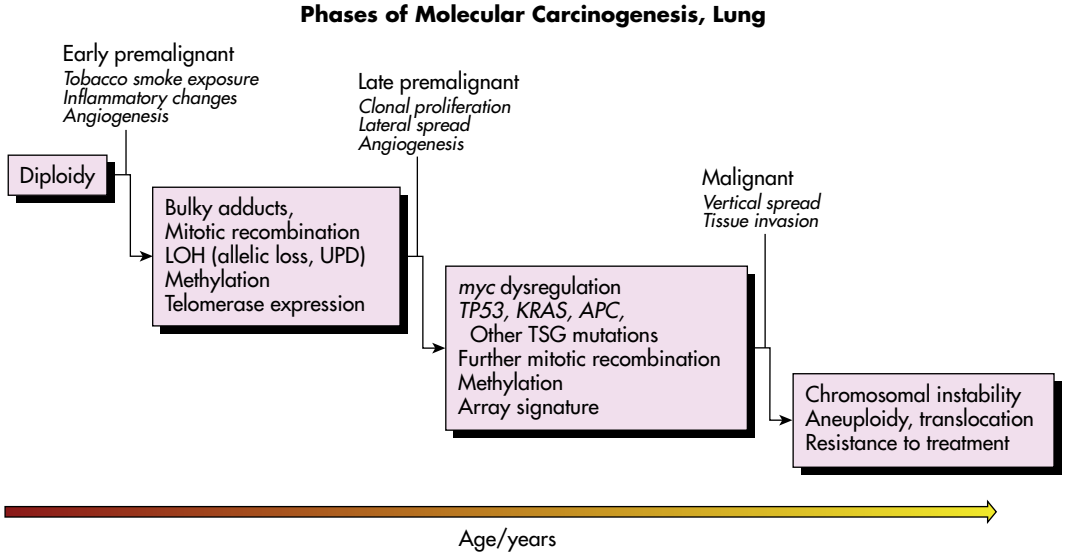

FIG. E2 The molecular pathology of smoking-related lung cancer begins with the direct interaction between metabolites of carcinogenic polyaromatic hydrocarbons in cigarette smoke with host DNA. This creates bulky adducts that affect DNA repair and create transcription errors. The result is a wide range of genomic losses, gains, translocations, and point mutations that account for the high degree of molecular heterogeneity in lung tumors with diverse physiologic effects. *LOH,* Loss of heterozygosity; *UPD,* uniparental disomy; *TSG,* tumor suppressor gene. (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

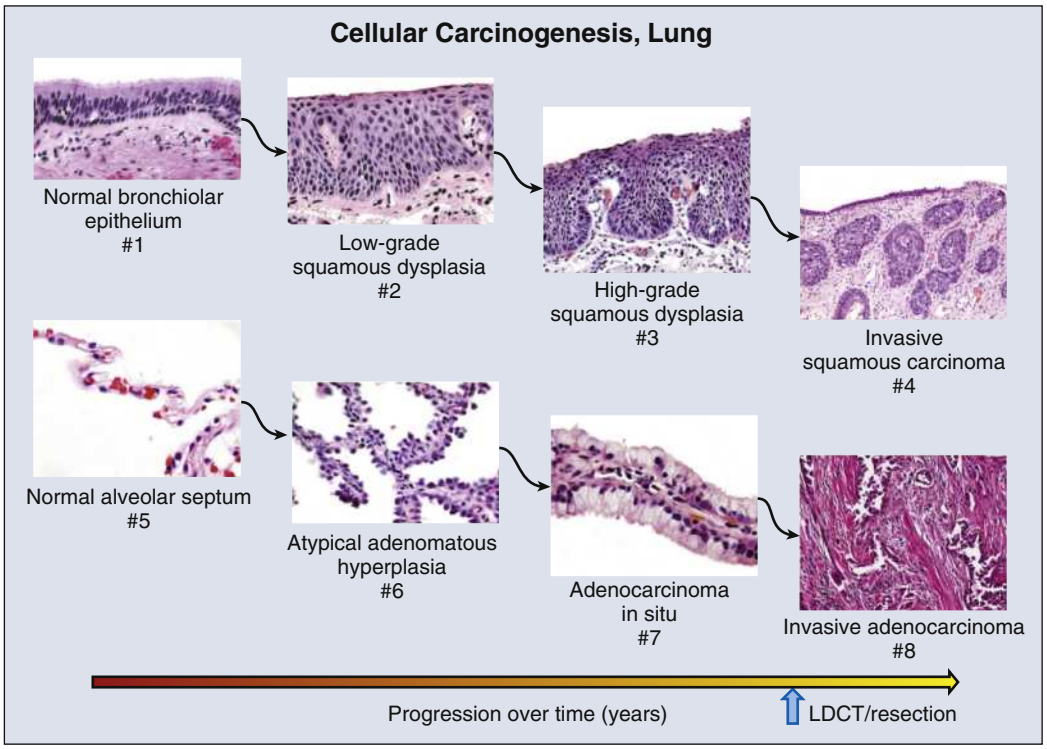

FIG. E3 Multistep carcinogenesis in the lung is complicated by the heterogeneity of tumor types that arise in separate locations in the respiratory tract. Squamous tumors typically form in the central airways, where they are thought to arise from *1,* the respiratory mucosa. The earliest premalignant lesion, *2,* low-grade squamous dysplasia, exhibits a polarity in which dark basaloid cells mature into large cells that flatten along the surface as seen in the cervix. *3,* High-grade squamous dysplasia exhibits less distinct maturation and a higher level of cytologic diversity. *4,* Invasive squamous cell carcinoma occurs when tumor cells extend in the underlying stroma, sometimes forming a mass visible on low–radiation dose computed tomography (LDCT). Adenocarcinomas typically arise peripherally in *5,* the alveoli and terminal bronchioles. The best-defined precursor lesion of adenocarcinoma is *6,* atypical adenomatous hyperplasia (AHH). These are small lesions (<5 mm) in which the alveolar architecture is preserved. *7,* Adenocarcinoma in situ (AIS) is a further progression of peripheral airway epithelium toward malignancy. This category represents a redefinition of the low-grade adenocarcinoma previously known as *bronchioloalveolar carcinoma.* These lesions are solitary small (≤3 cm) lesions consisting of a single cell layer that spreads in a nondestructive pattern of growth along the alveolar septae that is referred to as *lepidic* and is detectable as a ground-glass nodule by LDCT. *8,* Invasive adenocarcinoma spreads beyond the alveolar surface, forming a mass that appears solid on LDCT. The presence of a mass visible with LDCT suggests tumor. However, by the time this occurs, tumor is often invasive and must be treated aggressively. (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

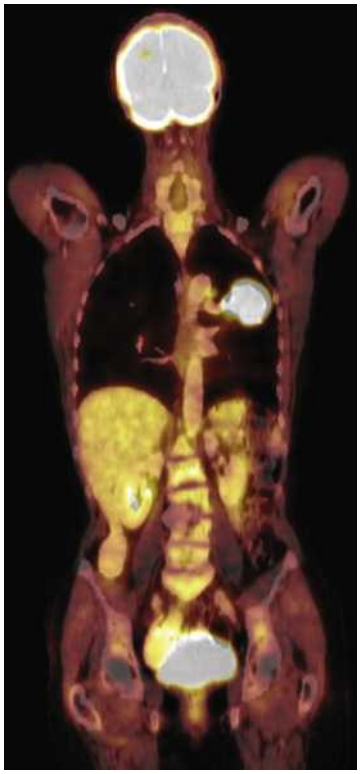

FIG. E6 Whole-body coronal [^{18}F]fluoro-2-deoxy-d-glucose positron emission tomography computed tomography (^{18}FDG-PET-CT) shows intense left upper lobe tracer accumulation in a patient with bronchogenic carcinoma. Note normal high tracer activity within the brain. (From Mason RJ: *Murray & Nadel's textbook of respiratory medicine*, ed 5, Philadelphia, 2010, Saunders.)

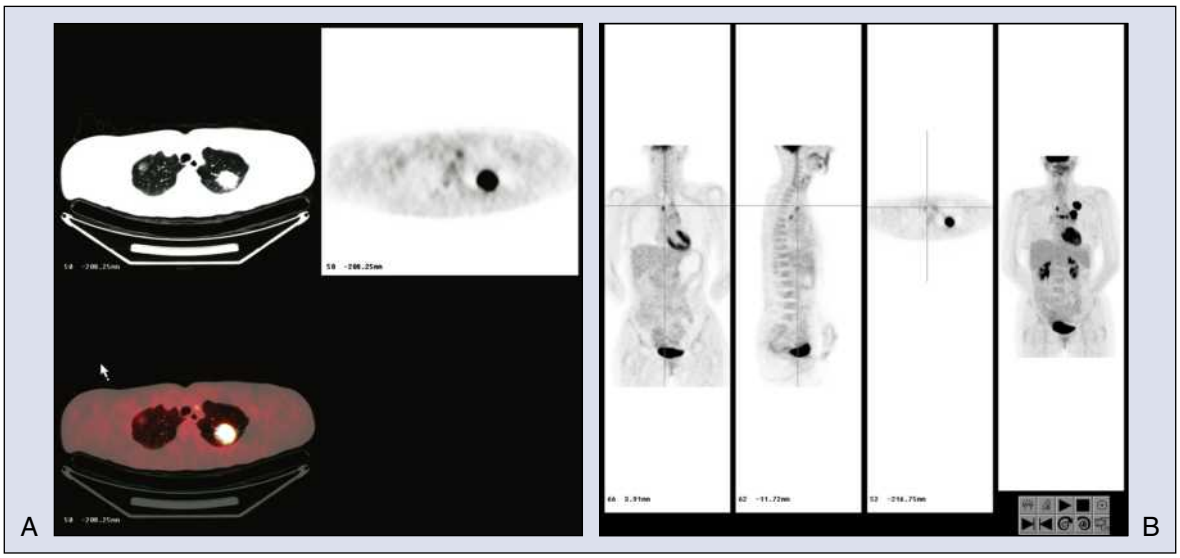

FIG. E7 A, Images obtained with positron emission tomography (PET) and computed tomography (CT). The upper left image is CT, the upper right image is PET, and the lower left image is a fusion of PET and CT data. The CT scan shows a smaller right apical nodule and a large left upper lung nodule. PET shows increased uptake of fluorine-18 fluorodeoxyglucose (^{18}F-FDG) in the left apical nodule, consistent with cancer, whereas only minimal uptake is seen in the right apical lesion, consistent with benign disease or a very low grade malignancy. Fused PET and CT images confirm the location of increased apical FDG uptake, as in the left lung nodule. **B,** Whole-body images from PET scans of the patient shown in **A**. The images include coronal, sagittal, transverse, and "projection" whole-body views, from left to right. They show cancer in the left upper lung, mediastinal involvement, and a right paratracheal tumor focus. Normal uptake is seen in the heart, brain, and excretory system (bladder). (From Niederhuber JE: *Abeloff's clinical oncology*, ed 6, Philadelphia, 2020, Elsevier.)

BASIC INFORMATION

DEFINITION

Lyme disease is a multisystem inflammatory disorder caused by the transmission of a spirochete, *Borrelia burgdorferi,* via the bite of infected *Ixodes* ticks, taking 36 to 48 hr for a tick to take a blood meal and transmit the infecting organism to the host.

SYNONYMS

Bannwarth syndrome (Europe)
Acrodermatitis chronica atrophicans

ICD-10CM CODES

A69.20	Lyme disease, unspecified
A69.21	Meningitis due to Lyme disease
A69.22	Other neurologic disorders in Lyme disease
A69.23	Arthritis due to Lyme disease
A69.29	Other conditions associated with Lyme disease

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): In the U.S., 4.4 cases/100,000 persons; it is the most common vector-borne infection in the U.S., with more than 30,000 new cases reported each yr. 90% of cases are found in Massachusetts, Connecticut, Rhode Island, New York, New Jersey, Pennsylvania, Minnesota, Wisconsin, and California. The area of transmission in the U.S. is expanding farther into the South and upper Northeast (Fig. E1). The disease also occurs in Europe and Asia with a different *Ixodes* tick vector. Table E1 summarizes principal vector ticks and spirochetes associated with Lyme borreliosis.
PEAK INCIDENCE: May to November
PREDOMINANT SEX: Male = female
PREDOMINANT AGE: Median age of 28 yr

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Lyme disease may present in the following stages:

- *Early localized stage (incubation period 3-30 days):* Early Lyme disease, erythema migrans (EM); skin rash, often at site of tick bite (the CDC has defined EM rash as an expanding red macule or papule that must reach at least 5 cm in size, with or without central clearing); target lesions from ECM can be found in 60% to 80% of localized infections; possible fever, myalgias 3 to 32 days after tick bite
- *Early disseminated stage (incubation period 3 to 6 wk):* Days to wk later; multiorgan system involvement, including CNS with aseptic meningitis–type picture or Bell palsy, joints (arthritis or arthralgias), cardiac including varying degrees of heart block; related to dissemination of spirochete
- *Late stage (incubation period months to years):* Months to years after tick exposure; affects central and peripheral nervous system, cardiac, joints

Common presenting signs and symptoms include:

- EM (Fig. E2). Most patients with EM (about 80%) have a single lesion but the bacteria can disseminate hematogenously to other sites in the skin and result in often smaller erythema migrans lesions.
- Lymphadenopathy, neck pains, pharyngeal erythema, myalgias, hepatosplenomegaly.
- Patients will complain of malaise, fatigue, lethargy, headache, fever/chills, neck pain, myalgias, back pain.

ETIOLOGY

B. burgdorferi transmitted from bite of an *Ixodes* tick (mostly in the nymph stage, but can also be from adult ticks). Human infection occurs through inoculation of spirochetes in infected saliva and usually requires tick attachment for more than 36 hours.

DIAGNOSIS

Clinical presentation, exposure to ticks in endemic area, and diagnostic testing for antibody response to *B. burgdorferi.* Serologic testing at early stages is usually negative; therefore, in early stage, documentation of erythema migrans lesion with a compatible epidemiologic history is sufficient for diagnosis, and laboratory testing is not indicated.

DIFFERENTIAL DIAGNOSIS

- Chronic fatigue/fibromyalgia
- Acute viral illnesses
- Babesiosis
- Human granulocytic anaplasmosis

WORKUP

Serologic testing is the principal means of laboratory diagnosis of Lyme disease. Current recommendations include using a sensitive enzyme immunoassay (EIA) or immunofluorescence assay, followed by a Western immunoblot assay for specimens yielding positive or equivocal results.

LABORATORY TESTS

- ELISA testing and if positive or equivocal then followed by a Western blot IgM and IgG (Table E2). A Western blot IgM assay is positive if 2 of 3 bands present. The Western blot IgG is positive if 5 of 10 bands present.
- An alternative serologic test is the VlsE C6 ELISA (C6 peptide), which detects an IgG response earlier and may be more sensitive than the ELISA, but its specificity is lower than the two-tier testing method.
- Early disease often is difficult to diagnose serologically, secondary to slow immune response.
- Culturing of skin lesions (EM) and polymerase chain reaction (PCR) of synovial fluid or CSF can also give the diagnosis of active infection.
- Fig. 3 is an algorithm for the diagnosis and treatment of arthritis associated with Lyme disease.

IMAGING STUDIES

- ECG
- Echocardiogram if conduction abnormalities are present with cardiac involvement
- CT scan, MRI of brain in patients with CNS involvement

TREATMENT

Early localized Lyme disease:

- Doxycycline 100 mg bid in adults (children: 2 mg/kg twice daily if ≥8 yr) [doxycycline offers the advantage of treating possible coinfection with the bacterial agents of ehrlichiosis] for 10 to 14 days or amoxicillin 500 mg tid for adults (children: 50 mg/kg per day in three divided doses) for 14 to 21 days.
- Alternative treatments for pregnancy and children ≦8 yr: Cefuroxime axetil 500 mg bid for 14 to 21 days (children: 30 mg/kg per day in two divided doses), azithromycin 500 mg PO for 7 to 10 days but should **not** be used as a first-line agent, as it is less effective than doxycycline and amoxicillin.
- A single dose of 200 mg doxycycline given within 72 hr of removing an engorged *Ixodes* tick can significantly reduce the risk of developing of Lyme disease in endemic areas and is reasonable prophylaxis in nonpregnant adults and children ≥8 yr old.

Early disseminated and late persistent infection:

- 28 days of treatment is often prescribed, although recent evidence supports treating patients with a 14-day course of oral doxycycline for early neurologic Lyme disease in ambulatory patients. Doxycycline and ceftriaxone appear equally effective for acute disseminated Lyme disease.[1]
- Arthritis: 28 days of doxycycline or amoxicillin plus probenecid.
- Neurologic involvement requires parenteral antibiotics. Those who fail to respond should be treated with IV ceftriaxone or cefotaxime.
- Ceftriaxone 2 g/day IV for 21 to 28 days; alternative: Cefotaxime 2 g q8h IV; alternative: Penicillin G 5 million U qid.
- Cardiac involvement: IV ceftriaxone or cefotaxime plus cardiac monitoring.
- Prolonged treatment with IV or PO antibiotic therapy for up to 90 days did not improve symptoms more than placebo.

Post–Lyme disease syndrome:

- Presence of disabling symptoms such as fatigue, malaise, diffuse pains, and poor concentration, which may be due to an exuberant host inflammatory response even in patients who have received proper antibiotic treatment
- Antibiotics are not indicated. Antibiotic treatment of patients with persistent unexplained symptoms despite previous antibiotic treatment of Lyme disease provides little, if any, benefit and carries significant risk
- Supportive care

[1]Sanchez E et al: Diagnosis, treatment, and prevention of Lyme disease, human granulocytic anaplasmosis, and babesiosis: a review, *JAMA* 315(16):1767-1777, 2016.

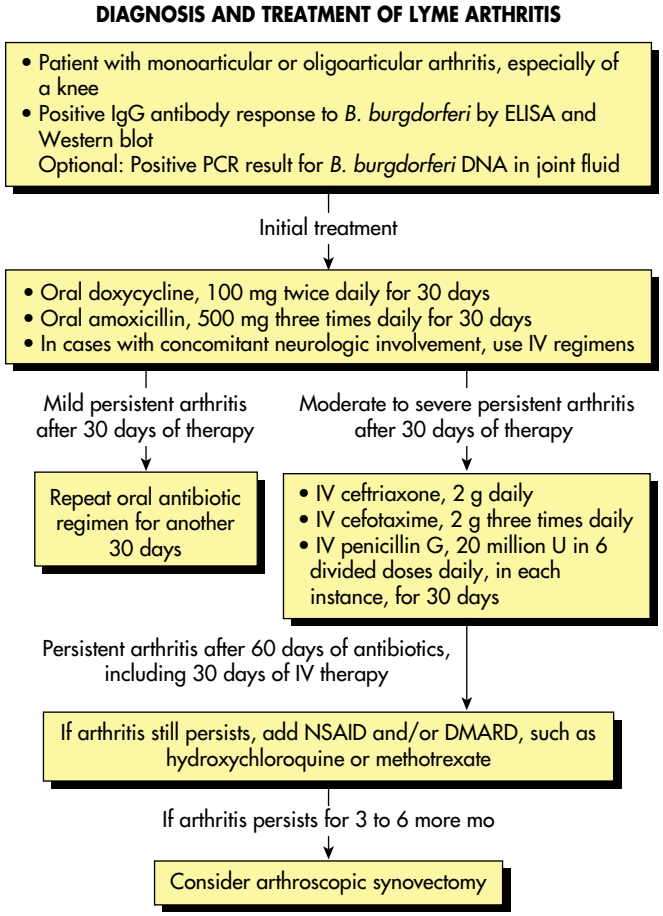

FIG. 3 Algorithm for the diagnosis and treatment of arthritis associated with Lyme disease. *DMARD,* Disease-modifying antirheumatic drug; *ELISA,* enzyme-linked immunosorbent assay; *Ig,* immunoglobulin; *IV,* intravenous; *NSAID,* nonsteroidal antiinflammatory drug; *PCR,* polymerase chain reaction. (From Hochberg MC: *Rheumatology*, ed 7, Philadelphia, 2019, Elsevier.)

DISPOSITION

- The patient often needs careful follow-up and supportive care for the arthralgia-neuritis symptoms.
- 10% to 20% of treated patients may have lingering symptoms of fatigue, disrupted sleep, and musculoskeletal complaints. Repeat episodes of EM in appropriately treated patients are due to reinfection and not to relapse.

REFERRAL

- To a neurologist if significant neurologic complications (meningitis, myelitis, ophthalmoplegia, Bell palsy)
- To a cardiologist if the patient develops evidence of cardiac conduction disturbances or pericarditis

PEARLS & CONSIDERATIONS

- A physician diagnosis of classic EM in an endemic region of Lyme disease is sufficient to make a definitive diagnosis.
- In some patients with Lyme disease, nonspecific complaints such as headache, fatigue, and arthralgia may persist for months after appropriate (and ultimately successful) antibiotic treatment. Long-term antibiotic treatment does not provide additional beneficial effects.
- There is no evidence of current or previous *Borrelia burgdorferi* infection in most patients evaluated at university-based Lyme disease referral centers. Psychiatric comorbidity and other psychological factors are prominent in the presentation and outcome of some patients who inaccurately ascribe longstanding symptoms to "chronic Lyme disease."
- It is important to realize that one tick bite can transmit Lyme disease *and* the bacterial agents of either ehrlichiosis or babesiosis (protozoan parasite), or even both, and these latter agents require separate serologic testing and possibly therapy. *Ehrlichiosis* is treated with doxycycline, but *Babesia* would require a different therapy. Powassan virus can also be transmitted by the *Ixodes* tick bite and causes an encephalitis seen in eastern Canada and northcentral, northeastern, and upper midwestern United States. Cases have been increasing.
- Tick bite protection: EPA-registered insect repellents containing DEET, picaridin, IR3535, oil of lemon eucalyptus (OLE), para-menthane-3,8-diol (PMD), or 2-undecanone can prevent ticks from attaching when applied, and can last for several hours. OLE and PMD products cannot be used on children under 3 yr of age.

BASIC INFORMATION

DEFINITION

Lymphangitis refers to the inflammation of lymphatic vessels due to infectious or noninfectious causes. Infectious causes include bacteria, mycobacteria, viruses, fungi, and parasites.

SYNONYMS

Nodular lymphangitis
Sporotrichoid lymphangitis

ICD-10CM CODE
I89.1 Lymphangitis

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Several hundred cases/yr of sporotrichoid lymphangitis, which is a fungal infection; bacterial lymphangitis more common but not reported.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

ACUTE LYMPHANGITIS:

- Commonly associated with a bacterial cellulitis
- Usually develops after cutaneous inoculation of microorganisms into the lymphatic vessels through disrupted skin or as a result of spread from a distal infection
- May or may not recognize a site of skin trauma (i.e., laceration, puncture, ulcer)
- In hours to days, distal appearance of erythema, edema, and tenderness, with linear erythematous streaks extending proximally to regional lymph nodes
- Possible lymphadenitis and fever
- Predisposition to group A streptococcal infection of the skin in those with uncontrolled diabetes mellitus, chronic lymphedema, and superficial fungal infections (e.g., tinea pedis)

SPOROTRICHOID OR NODULAR LYMPHANGITIS:

- Includes subcutaneous nodules that develop along the path of involved lymphatics
- Usually preceded by an episode of cutaneous inoculation or trauma to the hand
- Lesions apparent from one to several weeks after inoculation
- Initially, nodular or papular lesion; may ulcerate
- Pain is organism-dependent
- May have frank pus or a serosanguineous discharge
- Systemic complaints uncommon, but infection with certain microorganisms associated with fever, chills, myalgias, and headache

ETIOLOGY

- Acute lymphangitis: Usually associated with *Streptococcus pyogenes* (group A streptococcus), and to a lesser extent staphylococcus species, including community-acquired methicillin-resistant *S. aureus* (CA-MRSA)
- Nodular lymphangitis caused by one of several organisms:
  1. *Sporothrix schenckii* ("Rose gardener's disease," corn cultivation)
     a. Most common recognized cause in the U.S., usually in the Midwest
     b. Fungus found in soil and plant debris
  2. *Nocardia brasiliensis:* Gram-positive rod-shaped bacteria found in soil
  3. *Mycobacterium marinum:* Associated with trauma related to water (e.g., aquariums, swimming pools, fish)
  4. *Leishmania brasiliensis:*
     a. Protozoal parasite transmitted to humans by sand flies, mostly to travelers in endemic areas (Texas, rural Central and South America, Africa, subtropical Asia)
  5. *Francisella tularensis:* Gram-negative bacteria. Also causes lymphadenitis:
     a. Most often in Southern/Midwestern states (Arkansas, Missouri, Oklahoma)
     b. Associated with contact with infected mammals (e.g., rabbits, squirrels, cats), tick bites, and (rarely) water exposure

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Nodular lymphangitis
  1. Blastomyces or Coccidioides, Histoplasma, *Bacillus anthracis*, Mycetoma
- Insect or snake bites
- Filariasis

WORKUP

- Acute lymphangitis: Blood cultures
- Nodular lymphangitis: Various stains and cultures of drainage or biopsy specimens of inoculation sites

LABORATORY TESTS

- WBCs possibly elevated with cellulitis
- Eosinophilia common with helminthic infections
- Skin biopsy and microbiologic cultures may be necessary to confirm diagnosis in nodular lymphangitis

TREATMENT

NONPHARMACOLOGIC THERAPY

Limb elevation

ACUTE GENERAL Rx

- Penicillin possibly sufficient, but 1 wk of dicloxacillin or cephalexin 500 mg PO qid commonly used to ensure antistaphylococcal coverage; if CA-MRSA suspected, then use oral Bactrim DS one PO bid or clindamycin 300 mg PO q6H. Reserve vancomycin 1 g IV every 12 hr for patients requiring IV therapy
- If allergic to penicillin:
  1. Clindamycin 300 mg PO qid for 7 days *or*
  2. Erythromycin 500 mg PO qid for 7 days
  3. Levofloxacin 500 mg PO daily or moxifloxacin 400 mg PO daily for 7 days
- Nodular lymphangitis: Specific therapy directed at etiologic agent
- For superficial fungal infections: Treatment may prevent recurrence of acute lymphangitis

DISPOSITION

- Acute lymphangitis: Usually resolves with therapy
- Recurrent attacks: May lead to chronic lymphedema of limb, rarely resulting in elephantiasis nostras (nonfilarial elephantiasis)
- Nodular lymphangitis: Usually responds to appropriate therapy

REFERRAL

- If acute lymphangitis is more than a mild disease or if it involves the face
- If nodular lymphangitis or filariasis is suspected

PEARLS & CONSIDERATIONS

COMMENTS

- Outside of the U.S., initial episodes of filariasis caused by Brugia malayi resemble acute lymphangitis.
- Chronic lymphedema or elephantiasis results from recurrent episodes.
- For chronic lymphedema, adherence to limb elevation, compression/support stockings, and adequate glycemic control (for patients with diabetes) all can reduce risk of acute lymphangitis.

BASIC INFORMATION

DEFINITION

A primary role of the lymphatic system is to transport proteins from the interstitium to the heart. When the transport capacity of the lymphatic system is reduced, proteins accumulate in the interstitium. Accumulated proteins attract water, which creates a high protein swelling in the subcutaneous tissues called lymphedema.

SYNONYM

Elephantiasis

ICD-10CM CODES

I89.0	Lymphedema, not elsewhere classified
I97.2	Postmastectomy lymphedema syndrome
Q82.0	Hereditary lymphedema

EPIDEMIOLOGY & DEMOGRAPHICS

PRIMARY LYMPHEDEMA:

- Found in 1.1/100,000 people aged <20 yr
- Females outnumber males 3.5:1
- Incidence peaks between ages 12 and 16 (puberty)

SECONDARY LYMPHEDEMA: See specific etiology in the following.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Lymphedema is a slow-onset, progressive disease characterized by an asymmetrical, inflammatory swelling, traveling distal to proximal, that can affect any body part including limbs, trunk, head/neck, and genitals (Fig. 1). Box 1 summarizes lymphedema staging from the International Society of Lymphology.

STAGE 0: LATENCY:

- Decreased lymphatic system transport capacity due to primary or secondary etiology
- Subjective complaints of affected body part feeling heavy or achy
- No objective findings, no apparent swelling

STAGE I: REVERSIBLE:

- Edema is observable, soft, pitting and reversible with elevation.
- No secondary skin changes are present.

STAGE II: SPONTANEOUSLY IRREVERSIBLE:

- Skin becomes more firm/fibrotic, therefore less pitting.
- Edema does not reverse to normal with elevation.
- Possibility of infections (cellulitis), wounds, or weeping (lymphorrhea).

STAGE III: ELEPHANTIASIS:

- Skin becomes very firm/fibrotic, therefore nonpitting.
- Evidence of substantial skin changes (e.g., papillomas, lobules, "peau d' orange").

ETIOLOGY: Lymphedema is caused by a reduction in lymphatic system transport and is classified into primary and secondary forms.

PRIMARY LYMPHEDEMA:

- Occurs when the lymphatic system does not mature properly during fetal development
  1. Aplasia
  2. Hypoplasia
  3. Hyperplasia
- Can be familial, genetic, or hereditary
- Lymphedema congenital: Symptoms present at birth
- Lymphedema praecox: Symptoms onset before the age of 35 (commonly during puberty)
- Lymphedema tardum: Symptoms onset at the age of 35 or after

SECONDARY LYMPHEDEMA:

- Occurs secondary to a disruption or obstruction of the lymphatic system caused by:
  1. Filariasis (number one cause worldwide)
  2. Lymph node surgery/radiation due to cancer (number one cause in the U.S.)
  3. Other: Chronic venous insufficiency (CVI), deep vein thrombosis (DVT), infection, surgery/trauma, lipedema, and obesity

FIG. 1 Lymphedema before treatment.

BOX 1 Lymphedema Staging

Stage 0: Latent
- Impaired lymphatic function
- No evident edema; subclinical
- May last months or years before progression

Stage I: Spontaneously Reversible
- Early accumulation of protein-rich fluid
- Pitting edema
- Subsides with elevation

Stage II: Spontaneously Irreversible
- Accumulation of protein-rich fluid
- Pitting edema progresses to fibrosis
- Does not resolve with elevation alone

Stage III: Lymphostatic Elephantiasis
- Nonpitting
- Significant fibrosis
- Trophic skin changes

From International Society of Lymphology: The diagnosis and treatment of peripheral edema: 2009 consensus document of the International Society of Lymphology, *Lymphology* 42(2):51-60, 2009.

DIAGNOSIS

- Lymphedema is primarily a clinical diagnosis made on the basis of past medical history and objective findings that distinguish it from other causes of chronic edema.
- A Stemmer sign is often used to identify lymphedema (inability to pick up or pinch a fold of skin at the base of the second toe or finger).
- When physical examination is inconclusive, other available imaging tests can help make the diagnosis (see "Imaging Studies").

DIFFERENTIAL DIAGNOSIS

Other causes of edema that should be ruled out before treatment for lymphedema include cardiac, renal, hepatic, and thyroid dysfunction.

WORKUP

A detailed history and physical examination should help exclude most of the differential diagnoses.

LABORATORY TESTS

- Blood urea nitrogen, creatinine, liver function tests, albumin, urine analysis, and thyroid function tests are obtained to exclude possible systemic causes of edema.
- Genetic testing may be practical in defining a specific hereditary syndrome with a discrete gene mutation such as lymphedema distichiasis (*FOXC2*), Milroy disease (*VEGFR-3*), Meige disease, or Klippel-Trenaunay-Weber syndrome.

IMAGING STUDIES

- Lymphoscintigraphy: Diagnostic image of choice for lymphedema (if needed)
- Indocyanine green (ICG) fluorescent lymphography: Can now be used to identify sentinel nodes, to demonstrate superficial lymph channels and functional lymphatics, to indicate treatment pathways, and to confirm the effectiveness of therapeutic techniques
- Magnetic resonance imaging (MRI): Primarily used in tumor diagnosis
- Duplex ultrasound: Determines venous involvement in the edema
- Computed axial tomography (CAT): Distinguishes between fatty tissue and accumulations of protein-rich fluids
- Lymphography: Phased out in favor of less invasive techniques

TREATMENT

NONPHARMACOLOGIC THERAPY

- Complete decongestive therapy (CDT) is backed by longstanding research and experience as the primary treatment of choice for lymphedema in both children and adults (Fig. 2). It should be delivered by a certified

FIG. 2 Lymphedema after treatment.

lymphedema therapist (CLT). CDT involves a two-phase treatment program:

1. Phase 1—Reduce tissue congestion of affected body part with daily treatments:
   a. Manual lymph drainage.
   b. Skin care.
   c. Compression wrapping of limb.
   d. Decongestive exercises.
2. Phase 2—Maintain decongestion with home maintenance program:
   a. Daily use of elastic and inelastic compression garments that are properly fitted according to circumference and length to prevent lymphedema from returning.
   b. Compression is graduated; most of the compression is distal with decreasing compression in the stocking proximally.
   c. Different knits and compression classes are available for different stages of lymphedema.
   d. Choices of garments include below-the-knee stockings, thigh-high stockings, pantyhose, sleeves, bras, and truncal garments.

- Massage (or any modality that increases blood flow) can have negative effects on lymphedema by increasing vasodilation. Therefore it is contraindicated on the lymphedematous quadrants.
- Compression pumps have not been found to be effective in removing proteins from lymphedematous quadrants.
- Nutritional therapy (reducing the amount of proteins ingested) is ineffective in the treatment of lymphedema.

PHARMACOLOGIC THERAPY

No drugs have been shown to be beneficial in the treatment of lymphedema. Diuretics in particular have not been found to be effective in removing proteins from lymphedematous quadrants and may promote the development of volume depletion.

SURGERY

Surgery for lymphedema has been proven largely unsuccessful and should not be considered before CDT. Surgical procedures are divided into two types:

- Physiologic procedures: Those performed to improve lymph node drainage (e.g., anastomoses of the lymph system with the venous system, lymph node transplant).
- Excisional or debulking procedures: Those performed to excise the subcutaneous tissue (e.g., Charles procedure, Thompson procedure, the modified Homans procedure, and liposuction). Liposuction-circumferential suction-assisted lipectomy represents a newly proposed method to reduce morbidity involved in the traditional excisional techniques.

PEARLS & CONSIDERATIONS

- Lymphedema is a chronic, generally incurable but very manageable condition that requires lifelong care and attention along with psychosocial support.
- Children and adolescents (along with parents and adults) should be encouraged to pursue a normal life, participating in school activities and sports (preferably noncontact, such as swimming).
- Infections such as cellulitis should be treated promptly.
- If the etiology is filariasis caused by the parasites *Wuchereria bancrofti* or *Brugia malayi*, treatment is diethylcarbamazine citrate 5 mg/kg in divided doses for 3 wk.
- Patients with lymphedema commonly manifest psychiatric comorbidities as a result of their disease, such as anxiety, depression, adjustment problems, and difficulty in vocational, domestic, or social domains.
- Lymphedema can be complicated in rare cases by development of lymphangiosarcomata or other cutaneous malignancies.
- Gene therapy to develop new lymphangiosis in the affected body parts is a potential clinical remedy in the future.

SUGGESTED READINGS

Murdaca G et al: Current views on diagnostic approach and treatment of lymphedema, *Am J Med* 125, 2012.

Rockson SG: Lymphedema after breast cancer treatment, *N Engl J Med* 379:1937-1944, 2018.

Lymphogranuloma Venereum

BASIC INFORMATION

DEFINITION

Lymphogranuloma venereum (LGV) is a sexually transmitted, systemic disease caused by *Chlamydia trachomatis,* serovars L_1, L_2, or L_3.

SYNONYMS

Tropical bubo
Poradenitis inguinalis
LGV

ICD-10CM CODE
A55 Chlamydial lymphogranuloma (venereum)

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Rare; <300 cases/yr
PREVALENCE: Endemic in Africa, India, parts of Southeast Asia, South America, and the Caribbean
PREDOMINANT SEX: Male:female ratio is 5:1.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Primary stage:
- Primary lesion caused by multiplication of organism at site of infection
- Papule, shallow ulcer
- Herpetiform lesion at site of inoculation (most common)
- Incubation period of 3 to 21 days
- Most common site of lesion in women: Posterior wall, fourchette, or vulva
- Spontaneous healing without scarring

Second stage:
- Inguinal syndrome: Characteristic inguinal adenopathy (Fig. E1)
- Begins 1 to 4 wk after primary lesion
- Syndrome is the most frequent clinical sign of the disease
- Unilateral inguinal adenopathy in 70% of cases
- Symptoms: Painful, extensive adenitis (bubo) and suppuration may occur with numerous sinus tracts
- "Groove sign" signaling femoral and inguinal node involvement (20%); most often seen in men
- Involvement of deep iliac and retroperitoneal lymph nodes in women may present as a pelvic mass

Third stage (anogenital syndrome):
- Subacute: Proctocolitis
- Late: Tissue destruction or scarring, sinuses, abscesses, fistulas, strictures of perineum, elephantiasis

ETIOLOGY

Chlamydia trachomatis is the causative agent. There are three serotypes: L1, L2, and L3.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Inguinal adenitis, suppurative adenitis, retroperitoneal adenitis, proctitis, schistosomiasis.

FIG. E1 Lymphogranuloma venereum. (From James WD et al: *Andrews' diseases of the skin*, ed 12, Philadelphia, 2016, Elsevier.)

- Recall exposure in women or men who have sex with men (MSM) can result in proctocolitis mimicking inflammatory bowel disease, and clinical findings may include mucoid and/or hemorrhagic rectal discharge, anal pain, constipation, fever, and/or tenesmus.
- Section II describes the differential diagnosis of genital sores.

WORKUP

- Diagnosis is based on clinical suspicion and serology, epidemiologic information, and the exclusion of other etiologies for proctocolitis, inguinal lymphadenopathy, or genital or rectal ulcers. Biopsy is contraindicated because sinus tracts develop.
- Screening for other sexually transmitted diseases.
- A clinical algorithm for evaluation of genital ulcer disease is described in Section III, "Evaluation of Patients with Genital Lesions or Ulcers."

LABORATORY TESTS

- Genital and lymph node specimens (i.e., lesion swab or bubo aspirate) can be tested for *C. trachomatis* by culture or direct immunofluorescence, using nucleic acid amplification techniques, including real-time polymerase chain reaction (PCR).
- Additional molecular procedures (e.g., PCR-based genotyping) can be used to differentiate LGV from non-LGV *C. trachomatis* in rectal specimen; however, they are not widely available and results are not available in a timeframe that would influence clinical management.
- Complement fixation test:
  1. Titer >1:64 in active infection, lower titers may be nonspecific.
  2. Convalescent titers no difference.
- Microimmunofluorescence titers >1:256 might support the diagnosis of LGV in the appropriate clinical context.
- Cell culture of *Chlamydia* aspiration of fluctuant node yields highest rates of recovery.
- Complete blood count: Mild leukocytosis with lymphocytosis or monocytosis.
- Elevated sedimentation rate.
- Venereal Disease Research Laboratories (VDRL) and HIV screening to rule out other sexually transmitted diseases.

IMAGING STUDIES

Computed tomography scan for suspected retroperitoneal adenitis

TREATMENT

NONPHARMACOLOGIC THERAPY

- Avoid milk and milk products while taking medication.
- Practice sexual abstinence.
- Treat sexual partners. Persons who have had sexual contact with a patient who has LGV within 60 days before onset of the patient's symptoms should be examined, tested for urethral or cervical chlamydial infection, and treated with a chlamydia regimen (azithromycin 1 g orally single dose or doxycycline 100 mg orally twice a day for 7 days).

ACUTE GENERAL Rx

- Doxycycline 100 mg PO bid ×21 days
- Erythromycin base 500 mg PO qid ×21 days
- Surgical:
  1. Aspirate fluctuant nodes
  2. Incise and drain abscesses
- Combination of medical and surgical treatment may be necessary

CHRONIC Rx

- Longer course of therapy will be needed for chronic or relapsing cases, which may be caused by reinfection and/or inadequate treatment.
- A rectal stricture requires a colostomy.
- Surgery should be considered only after antibiotic treatment.

DISPOSITION

Good prognosis with early treatment, usually resulting in complete resolution of symptoms.

REFERRAL

Surgical consultation if patient develops obstruction, fistula, or rectal stricture. May need referral to plastic surgeon if patient has lymphatic obstruction.

PEARLS & CONSIDERATIONS

COMMENTS

- The most common clinical manifestation of LGV among heterosexuals is tender inguinal and/or femoral lymphadenopathy that is typically unilateral.

- Rectal exposure in women or MSM can result in proctocolitis mimicking inflammatory bowel disease.
- Pregnant and lactating women should be treated with erythromycin regimen (doxycycline contraindicated in pregnancy).
- Congenital transmission does not occur, but infection may be acquired through an infected birth canal.
- Persons with both LGV and HIV infection should receive the same regimens as those who are HIV negative. Prolonged therapy may be required, and delay in resolution of symptoms may occur.
- Patient education materials may be obtained through local and state health clinics.

RELATED CONTENT

Lymphogranuloma Venereum (Patient Information)

AUTHOR: **Emily Rosenfeld, MD, MPH**

BASIC INFORMATION

DEFINITION

Lynch syndrome is a hereditary predisposition to malignancy of the colon that is explained by a germline mutation in a DNA mismatch repair gene. The Lynch syndrome phenotype is characterized by a predominance of cancers on the right side of the colon and a propensity for synchronous and metachronous colorectal cancers.

SYNONYMS

Hereditary nonpolyposis colorectal cancer
HPNCC
Hereditary site-specific colon cancer

ICD-10 CM CODE

C18.9 Malignant neoplasm of colon, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

The lifetime risk for developing colon cancer in the U.S. is approximately 6%. Up to 30% of colon cancer is inherited and 3% may be attributable to Lynch syndrome. The incidence of Lynch syndrome is estimated to be between 1:660 and 1:2000. Lynch syndrome is the most common form of hereditary colon cancer. The average age of diagnosis for Lynch syndrome is 45 yr, although diagnosis can occur as early as the 20s or as late as the 70s.

RISK FACTORS: Family history of colon cancer or other hereditary nonpolyposis colorectal cancer (HNPCC)-related cancers such as endometrial (up to 40% of women with Lynch syndrome may develop endometrial cancer), biliary tract, ovarian, stomach, upper urinary tract, or brain. Table 1 summarizes the risk of Lynch syndrome.

GENETICS: Autosomal-dominant inheritance pattern.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Changes in bowel habits (prolonged constipation)
- Melena
- Hematochezia
- Abdominal pain
- Unexplained weight loss
- Decreased appetite
- Right sided colon cancer (70% to 85% of cases)

TABLE 1 Risk of Lynch Syndrome

Condition	Risk (%)
Endometrial cancer at any age	1.8
Endometrial cancer diagnosed before 50 yr of age	9
Endometrial and colon cancer at any age	18
Endometrial and colon cancer before 50 yr of age	43
Endometrial and ovarian cancer	7

From Disaia PJ et al: *Clinical gynecologic oncology*, ed 9, Philadelphia, 2017, Elsevier.

ETIOLOGY

Lynch syndrome is thought to be secondary to germline mutations in DNA mismatch repair genes. The predominant genes involved are *MSH2* and *MLH1,* which are tumor suppressor genes, although other genes have documented involvement (*PMS1, PMS2, MSH6,* and *EpCAM*). Mutations in these genes prevent repair of DNA mismatches during DNA replication. This is most prevalent in regions of DNA called microsatellites, causing DNA microsatellite instability and leading to an increased risk for malignancy, especially colon cancer. *MSH6* mutations are associated with a markedly lower cancer risk than *MLH1* or *MSH2* mutations.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Familial adenomatosis polyposis
- Peutz-Jeghers syndrome
- Juvenile polyposis
- Nonhereditary colorectal cancer. Table 2 compares Lynch syndrome and sporadic colorectal cancer
- Gardner syndrome

WORKUP

If an individual presents with numerous adenomatous polyps or has multiple relatives with cancer at a young age, a family history complete with pedigree must be obtained. Clinical diagnosis of the Lynch syndrome can be made with the Amsterdam or Bethesda criteria (Box 1) as well as newer models such as prediction model for gene mutations 5 (PREMM5).

- Revised Amsterdam (II) criteria (must meet all criteria):
  1. HNPCC-associated carrier diagnosis in at least three individuals in the family
  2. One of the patients is a first-degree family member of two other patients
  3. Involved patients occur in at least two successive generations with diagnosis of HNPCC
  4. At least one diagnosis in family of HNPCC was made before age 50
  5. The diagnoses are histologically confirmed
  6. Familial adenomatous polyposis is excluded.
- Bethesda criteria (must meet all criteria):
  1. Colorectal cancer before age 50
  2. Multiple colorectal cancers or other HNPCC-related cancers such as biliary tract, endometrial, stomach, or ovary
  3. Colorectal cancer with microsatellite instability histology <60 yr of age
  4. Colorectal cancer or HNPCC-related cancer in first-degree relative <50 yr of age
  5. Colorectal cancer or HNPCC-related cancer in at least two first- or second-degree relatives, any age
- If criteria for the Lynch syndrome are not met, no further analysis is necessary (although a genetic syndrome cannot be definitively excluded and genetic referral may be warranted)

LABORATORY TESTS

- If a patient meets criteria for Lynch syndrome, immunohistochemistry can be performed for the presence or absence of mismatch repair genes MLH1, MSH2, MSH6, and PMS2. Rarely, MLH3 is identified.
- Microsatellite instability analysis should also be performed if criteria for Lynch syndrome are met.

TREATMENT

- If the mutation has been identified in a family member, screening for this mutation can be performed via genetic testing. Informed consent must be obtained after a thorough explanation has been provided to each individual. Criteria for referral to a genetic counselor for suspected Lynch syndrome is summarized in Table 3.
- Surveillance using colonoscopy can be performed in individuals who screen positive, while those who screen negative can be discharged. The mismatch repair gene that is mutated guides screening.

TABLE 2 Comparison of Clinical Features in Lynch Syndrome and Sporadic Colorectal Cancer

Clinical Feature	Lynch Syndrome	Sporadic Colorectal Cancer
Mean age at diagnosis (yr)	45	67
Multiple colon cancers	35%	4%-11%
Synchronous colon cancers	18%	3%-6%
Metachronous colon cancers	24%	1%-5%
Proximal location of the initial cancer*	72%	35%
Increased risk of malignant tumors at other sites	Yes	No
Mucinous and poorly differentiated colon cancers	Common	Infrequent
Prognosis	Favorable†	Variable

*Proximal to the splenic flexure.
†Patients whose tumors demonstrate microsatellite instability have a more favorable prognosis than those with microsatellite-stable tumors.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

BOX 1 Amsterdam II Criteria for Hereditary Nonpolyposis Colorectal Cancer (Lynch Syndrome)

Criteria defined by the International Collaborative Group on Hereditary Nonpolyposis Colorectal Cancer
At least three relatives with CRC (one must be a first-degree relative of the other two) or a Lynch syndrome–associated cancer*
- CRC involving at least two successive generations
- One or more cancer cases before age 50 yr
- Familial adenomatous polyposis should be excluded
- Tumors should be verified by histologic examination

*Endometrium, ovary, stomach, ureter/renal pelvis, pancreas, brain, hepatobiliary tract, small intestine, and multiple sebaceous adenomas and carcinomas and keratoacanthomas in the Muir-Torre variant of Lynch syndrome.
CRC, Colorectal cancer.
From Feldman M, Friedman LS, Brandt LJ: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE 3 Criteria for Referral to a Genetic Counselor for Suspected Lynch Syndrome

Bethesda guidelines
Amsterdam Criteria fulfilled
Persons with two relatives with Lynch syndrome
Colorectal cancer and first-degree relative with a Lynch cancer before 45 yr or a first-degree relative with an adenoma before 40 yr of age
Colorectal cancer or endometrial cancer before 45 yr of age
Right-sided, undifferentiated colon cancer before 45 yr of age
Signet ring colon cancer before 45 yr of age
Adenoma before 40 yr of age

From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

- According to the Netherlands Surveillance Protocol, for example, individuals with mutations in *MLH1, MSH2,* or *MSH6* should have colonoscopies every 1 to 2 yr starting at age 20 to 25 yr; urine cytology every 1 to 2 yr starting at age 30 to 35 yr; esophagogastroduodenoscopy every 1 to 2 yr starting at age 30 to 35 yr; and, in females, ultrasound of endometrium and CA-125 every 1 to 2 yr starting at age 30 to 35 yr.
- *Helicobacter pylori* testing is also indicated in patients with Lynch syndrome or at high risk for it.
- Aspirin may be protective against colorectal cancer in Lynch syndrome patients.

REFERRALS

- To gastroenterology for surveillance colonoscopies
- To genetic counselor if patient satisfies Bethesda criteria
- To psychologist as necessary for psychological support

PEARLS & CONSIDERATIONS

- Before genetic testing is instituted, informed consent must be obtained because consequences of this testing include the necessity of lifelong screenings such as colonoscopies.
- The risk of pancreatic cancer is increased in families with Lynch syndrome compared with the U.S. population.
- **Familial Colorectal Cancer Type X** refers to patients who meet the Amsterdam criteria for HPNCC but have no molecular evidence of a mismatch repair (MMR) deficiency. These patients have a lower risk of colon cancer and no increased risk of extracolonic cancer compared to those with Lynch syndrome.

PATIENT & FAMILY EDUCATION

BASIC INFORMATION

DEFINITION

Macular degeneration, usually referred to as *age-related macular degeneration* (AMD), is an acquired degeneration of the retinal pigment epithelium and subsequently the neurosensory retina and choroid resulting in loss of central vision. The etiology is not known but a combination of genetic predisposition to immune- and complement-mediated inflammation and certain risk factors plays an important role. Nonexudative (or "dry") AMD is the most common, but exudative (or "wet") AMD is the most visually devastating.

SYNONYMS

AMD
ARMD

ICD-10CM CODES

H35.31	Nonexudative age-related macular degeneration
H35.32	Exudative age-related macular degeneration

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.):

- Leading cause of irreversible blindness in people ≥50 yr in the developed world.
- Increases with age.
- In 2010, 2.1 million Americans over the age of 40 had advanced AMD. The number is expected to more than double to 5.4 million by 2050.
- About 10% of patients with AMD have the neovascular form manifested by an often rapid decrease in central visual acuity caused by bleeding and scarring secondary to choroidal neovascularization.

PEAK INCIDENCE:

- Ages 75 to 80 yr
- Risk increases threefold in patients over the age of 75 as compared with younger age groups

PREVALENCE (IN U.S.):

- Varies, but 6.5% of people >40 yr have some signs of macular degeneration, and 0.8% have late AMD.
- In the U.S., approximately 30% of people over the age of 75 have some form of macular degeneration.

PREDOMINANT SEX: Males and females are affected equally (15% of white women >80 yr have severe AMD)

PREDOMINANT AGE: >50 yr

RISK FACTORS:

- Advancing age, especially over 70
- Genetic factors
- History of smoking within past 20 yr
- Dietary factors (low intake of antioxidants, zinc, and omega-3 fatty acids; high fat intake)
- Obesity
- White race

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Decreased central vision, distortion of vision (metamorphopsia), poor night vision
- Drusen, atrophy, macular hemorrhage, pigmentation, macular edema, subretinal fluid
- The most common abnormality seen in AMD is the presence of drusen, or yellowish deposits deep to the retina
- Choroidal neovascular membrane (CNVM) develops with rapid change in vision due to leakage of exudative fluid and hemorrhage.

ETIOLOGY

- Oxidative and inflammatory changes in the retinal pigment epithelium due to a combination of environmental factors and genetic predisposition
- Genetics: 19 genes with mutations have been identified—dysregulation of the alternate complement system among other biochemical pathways
- Pigmentary and vascular changes with exudate, edema, and ultimately scar tissue development in exudative AMD
- Dry-type atrophy of the macula retinal pigment epithelium in nonexudative AMD
- The main mediator of neovascularization in wet AMD is vascular endothelial growth factor (VEGF). It induces angiogenesis and increases inflammation and vascular permeability

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Polypoidal choroidal vasculopathy (PCV)
- Central serous chorioretinopathy
- Pattern dystrophy of the retinal pigment epithelium
- Drug toxicity (hydroxychloroquine, deferoxamine)
- Multifocal choroiditis (inflammatory disease of the choroid and retinal pigment epithilium (RPE))
- Histoplasmosis and high myopia (less common causes of CNVM)
- Angioid streaks
- Trauma with macular scar

WORKUP

- Careful history including family history of ocular disease
- Complete eye examination including slit lamp biomicroscopy
- Optical coherence tomography (OCT) is essential

IMAGING STUDIES

- High-resolution OCT
- OCT angiography
- Fluorescein angiography
- Fundus autofluorescence
- Possibly indocyanine green angiography if other diseases are being considered

TREATMENT

NONPHARMACOLOGIC THERAPY

- There is no laser treatment for dry AMD.
- Photodynamic treatment with verteporfin can be used in the rare case of exudative AMD that does not respond to intravitreal pharmacotherapy.
- Thermal laser (argon) for certain classic membranes (CNVM) is rarely used in the era of biologics.

ACUTE GENERAL Rx

- The introduction of therapies blocking VEGF has dramatically changed the management of AMD and is now the standard of care in the management of neovascular AMD. Intravitreal injections of anti-VEGF agents (ranibizumab, bevacizumab, and aflibercept) are first-line treatments for neovascular AMD. Intravitreal administration of ranibizumab, a humanized antibody fragment that neutralizes all active forms of VEGF A, was shown to stabilize or improve vision in 95% of patients compared to 65% of patients treated with verteporfin photodynamic therapy (PDT). Aflibercept is a soluble protein that acts as a VEGF receptor decoy and is the most recently FDA-approved intravitreal therapy. Randomized controlled trials showed it to be noninferior to ranibizumab. Bevacizumab, a full-length monoclonal antibody to VEGF, is used off-label as intravitreal therapy. Its cost per intravitreal dose is significantly lower than that of ranibizumab and aflibercept. However, several comparative effectiveness trials have shown bevacizumab to be non-inferior to ranibizumab.
- A major concern regarding anti-VEGF treatment is the potential increased risk of stroke and cardiovascular disease but no study to date has shown an increased incidence due to intravitreal therapy.
- Laser photocoagulation therapy may be useful in patients with extrafoveal lesions but is no longer routinely recommended for wet AMD.

CHRONIC Rx

- Age Related Eye Disease Study 1 and 2 (AREDS): A large randomized controlled trial showed that supplementation with the antioxidant vitamins C (500 mg) and E (400 IU), beta carotene (15 mg), and the micronutrient zinc (80 mg zinc oxide and 2 mg cupric oxide to prevent zinc-induced anemia) in patients with intermediate nonexudative AMD resulted in a 25% risk reduction of progression to advanced AMD at 5 yr.
- AREDS 2 formula eliminates beta carotene and replaces it with 10 mg lutein and 2 mg zeaxanthin, thus avoiding the risk of lung cancer in former smokers.

DISPOSITION

- Follow closely by ophthalmologist, retinal specialist
- Frequency of follow-up determined by severity of disease
- Patients should self-monitor with Amsler grid daily and report changes immediately
- Smoking cessation, sunglasses with UVA and UVB protection, diet high in green leafy vegetables and fish
- Most anti-VEGF treatment failures are due to missed follow-up visits. Patients should be reminded repeatedly to call if their vision worsens

PEARLS & CONSIDERATIONS

COMMENTS

- Recent trials with embryonic stem cell transplants have shown promise in macular degeneration. Although stem cells represent new therapeutic strategies to repair and regenerate tissues damaged by disease or injury, much remains to be learned about how stem cells and their derivatives can be manufactured and delivered safely. Recent reports show success with autologous-induced stem-cell–derived retinal cells for macular degeneration,[1] whereas others performed outside of clinical trial settings have resulted in vision loss after intravitreal injection of autologous "stem cells" for AMD.[2] The International Society for Stem Cell Research has recently released guidelines for clinical translation of stem cells.[3,4]
- Statistically, the vision of only 1 of 10 affected persons can be saved, but the disease is so devastating that vigorous therapy should be considered in all patients.
- Vitamins with zinc and antioxidants may slow progression of AMD.
- Quitting smoking significantly reduces the risk of developing AMD.

Malabsorption

BASIC INFORMATION

DEFINITION

Malabsorption is the diminished intestinal absorption of dietary nutrients. The majority of malabsorption is due to either congenital or acquired defects in the membrane transport system, absorption, and brush border processing in the intestinal epithelium.

SYNONYM

Maldigestion

ICD-10CM CODES

K90.4	Malabsorption due to intolerance, not elsewhere classified
K90.89	Other intestinal malabsorption
K90.9	Intestinal malabsorption, unspecified
K91.2	Postsurgical malabsorption, not elsewhere classified

EPIDEMIOLOGY & DEMOGRAPHICS

PREDOMINANT SEX AND AGE: More common in females, with a mean age of 40
GENETICS: HLA-DQ2 present in 95% of celiac disease

RISK FACTORS:
- Excessive alcohol consumption
- History of celiac disease
- History of irritable bowel disease (IBD)
- Intestinal surgery

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Most commonly nonspecific symptoms such as abdominal flatulence and distention are seen.
- Due to the osmotic load from maldigestion/malabsorption, watery diarrhea may be present. In the case of fat digestive disorder, steatorrhea ensues.
- Weight loss is very common but many patients are able to compensate by increased caloric load. Diffuse disease often has much more pronounced weight loss.
- Chronic protein malabsorption can cause hypoalbuminemia, leading to edema and ascites.
- Both microcytic and macrocytic anemia can result from micronutrient deficiency (iron/B_{12}). These patients can be pale and present with fatigue.
- Bleeding disorders from vitamin K deficiency can lead to ecchymosis, melena, and hematuria.
- Vitamin D deficiency can lead to bone disorders. Secondary hyperparathyroidism can be a presenting feature.
- Electrolyte and vitamin deficiency can lead to neurologic disorders such as ataxia, weakness, and neuropathy, and may have positive Chvostek or Trousseau sign.
- Autoimmune disease-specific dermatologic findings such as alopecia, pellagra, erythema nodosum, pyoderma gangrenosum, cheilosis, glossitis, and aphthous ulcers may be present.
- Cardinal clinical features of specific malabsorptive disorders are summarized in Table 1.

ETIOLOGY

- Can be congenital or acquired.
- Disease-specific etiology. Mechanisms of malabsorption, malabsorbed substrates, and representative causes are summarized in Table 2.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Crohn disease
- Celiac disease
- Hartnup disease
- Chronic pancreatitis
- Pancreatic insufficiency
- Cystic fibrosis
- Short bowel syndrome

TABLE 1 Cardinal Clinical Features of Specific Malabsorptive Disorders

Disorder	Cardinal Clinical Features
Adrenal insufficiency	Skin darkening, hyponatremia, hyperkalemia
Amyloidosis	Renal disease, nephrotic syndrome, cardiomyopathy, neuropathy, carpal tunnel syndrome, macroglossia, hepatosplenomegaly
Bile acid deficiency	Ileal resection or disease, liver disease
Carcinoid syndrome	Flushing, cardiac murmur
Celiac disease	Variable symptoms: Dermatitis herpetiformis, alopecia, aphthous mouth ulcers, arthropathy, neurologic symptoms, and (life-threatening) malnutrition; elevated liver biochemical test levels, mild iron deficiency
Crohn disease	Arthritis, aphthous mouth ulcers, episcleritis, uveitis, pyoderma gangrenosum, erythema nodosum, abdominal mass, fistulas, perianal fistulae, primary sclerosing cholangitis (PSC), laboratory signs of inflammation
CF	Chronic sinopulmonary disease, meconium ileus, distal intestinal obstruction syndrome (DIOS), elevated sweat chloride
Cystinuria, Hartnup disease	Kidney stones, dermatosis
Diabetes mellitus	Long history of diabetes and diabetic complications
Disaccharidase deficiency	Bloating and cramping, intermittent diarrhea
GI fistulas	Previous intestinal surgery or trauma, Crohn disease
Glucagonoma	Migratory necrolytic erythema, enlarged gallbladder
Hyperthyroidism, hypothyroidism	Symptoms and signs of thyroid disease
Hypogammaglobulinemia	Recurrent infections
Intestinal ischemia	Other ischemic organ manifestations; abdominal pain with eating (chronic mesenteric ischemia)
Lymphoma	Enlarged mesenteric or retroperitoneal lymph nodes, abdominal mass, abdominal pain, fever
Mastocytosis	Urticaria pigmentosum, peptic ulcer
Mycobacterium avium complex infection	AIDS
Pancreatic insufficiency	History of pancreatitis, abdominal pain, or alcoholism; large-volume fatty, oily stools; passage of orange oil
Parasitic infection	History of travel to endemic areas
PBC	Jaundice, itching
Scleroderma	Dysphagia, inability to open the mouth widely, Raynaud phenomenon, skin tightening
SIBO	Previous intestinal surgery, motility disorder (scleroderma, pseudo-obstruction), small intestinal diverticula, strictures
Tropical sprue	History of travel to endemic area
Tuberculosis	Specific history of exposure, living in or travel to endemic area, immunosuppression, abdominal mass or intestinal obstruction, ascites
Whipple disease	Lymphadenopathy, fever, arthritis, cerebral symptoms, heart murmur (pulmonary valve), oculomasticatory myorhythmia
ZES	Peptic ulcers, diarrhea

AIDS, Acquired immunodeficiency syndrome; *CF,* cystic fibrosis; *GI,* gastrointestinal; *PBC,* primary biliary cholangitis; *SIBO,* small intestinal bacterial overgrowth; *ZES,* Zollinger-Ellison syndrome.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE 2 Mechanisms of Malabsorption, Malabsorbed Substrates, and Representative Causes

Pathophysiologic Mechanism	Malabsorbed Substrate(s)	Representative Causes
Maldigestion		
Conjugated bile acid deficiency	Fat Fat-soluble vitamins Calcium Magnesium	Hepatic parenchymal disease Biliary obstruction SIBO with bile acid deconjugation Ileal bile acid malabsorption CCK deficiency
Pancreatic insufficiency	Fat Protein Carbohydrate Fat-soluble vitamins Vitamin B_{12} (cobalamin)	Congenital defects Chronic pancreatitis Pancreatic tumors Inactivation of pancreatic enzymes (e.g., ZES)
Reduced mucosal digestion	Carbohydrate	Congenital defects Acquired lactase deficiency
	Protein	Generalized mucosal disease (e.g., celiac disease, Crohn disease)
Intraluminal consumption of nutrients	Vitamin B_{12} (cobalamin)	SIBO Helminthic infections (e.g., *Diphyllobothrium latum* infection)
Malabsorption		
Reduced mucosal absorption	Fat Protein Carbohydrate Vitamins Minerals	Congenital transport defects Generalized mucosal diseases (e.g., celiac disease, Crohn disease) Previous intestinal resection or bypass Infections Intestinal lymphoma
Decreased transport from the intestine	Fat Protein	Intestinal lymphangiectasia Primary Secondary (e.g., solid tumors, Whipple disease, lymphomas) Venous stasis (e.g., from heart failure)
Other Mechanisms		
Decreased gastric acid and/or intrinsic factor secretion	Vitamin B_{12}	Pernicious anemia Atrophic gastritis Previous gastric resection
Decreased gastric mixing and/or rapid gastric emptying	Fat Calcium Protein	Previous gastric resection Autonomic neuropathy
Rapid intestinal transit	Fat	Autonomic neuropathy Hyperthyroidism

CCK, Cholecystokinin; *SIBO,* small intestinal bacterial overgrowth; *ZES,* Zollinger-Ellison syndrome.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease,* ed 10, Philadelphia, 2016, Elsevier.

- Neoplasm
- Abetalipoproteinemia
- Lactose intolerance
- Small intestine bacterial overgrowth
- Chronic atrophic gastritis
- Zollinger-Ellison syndrome
- Chronic cholestasis
- Cirrhosis

WORKUP

- A detailed history including alcohol consumption and surgical history as well as autoimmune disease can help diagnose the underlying disease. It is important to screen for anemia and electrolyte abnormalities due to malabsorption.
- Table 3 summarizes malabsorptive diseases or conditions in which noninvasive tests can establish malabsorption or provide a diagnosis.

LABORATORY TESTS

- CBC, serum iron, Vitamin B_{12}, and folate to detect for anemia.
- **Prothrombin time:** Elevated PT can suggest vitamin K deficiency.
- **Fat malabsorption:** The gold standard is the 72-hour stool elastase or fat collection. More than 6/g day in the stool is pathologic. This test can be cumbersome so other options are available. Sudan III stain and acid steatocrit tests are qualitative measures of steatorrhea. Serologic testing for celiac disease should be considered as well.
- **Carbohydrate malabsorption:** Carbohydrate malabsorption leads to fermentation of the undigested carbohydrates by intestinal bacteria.
- The urinary D-xylose test for carbohydrate absorption in the small intestine. After loading with D-xylose, urinary D-xylose levels are measured. Low levels suggest intestinal malabsorption.
- Lactose intolerance can be tested by the lactose tolerance test or the breath test. The lactose tolerance test measures blood glucose after lactose administration. Development of symptoms or inadequate increase in blood sugar is indicative of lactose intolerance. H_2/CO_2 breath tests using specific forms of carbohydrates can detect malabsorption as well.
- **Protein malabsorption:** Protein malabsorption is likely due to small intestinal bacterial overgrowth or protein gastroenteropathies. Alpha-1 antitrypsin clearance or 99mTc-albumin gamma camera scintigraphy may aid in this diagnosis.
- **Pancreatic insufficiency:** Fecal elastase and chymotrypsin levels can distinguish from pancreatic and intestinal causes.
- **Vitamin deficiency:** It is important to assess serum vitamin B_{12} and methylmalonic acid levels. Schilling test is rarely used but can be useful in some cases.
- **Bile acid malabsorption:** Quantitative stool bile acid measurement is the preferred method of diagnosis. SeHCAT test (selenium homocholic acid taurine test) is another option but less likely used.
- **Bacterial overgrowth:** This can be detected with endoscopic jejunal aspirate culture or a less invasive hydrogen breath test.
- Table 4 summarizes useful laboratory tests for evaluating patients with suspected malabsorption and for establishing possible nutrient deficiencies.

IMAGING STUDIES

- Abdominal ultrasound can identify thickened small bowel wall
- Endoscopy for visualization and biopsy
- Small bowel follow through
- Abdominal CT/MRI
- Endoscopic retrograde cholangiopancreatography/magnetic resonance cholangiopancreatography/endoscopic ultrasound for identification of pancreatic abnormalities
- Capsule endoscopy

Rx TREATMENT

Involves identification and treatment of the underlying illness, treatment of diarrhea, and nutritional repletion

NONPHARMACOLOGIC THERAPY

- A gluten-free diet in patients with celiac disease. Avoidance of lactose-containing product in lactose intolerance.
- Avoidance of caffeine and high sugar containing compounds has been found to decrease diarrhea in some cases.

ACUTE GENERAL Rx

- Control of the underlying disease should be primary goal.
- It is also essential to control any volume and electrolyte abnormalities that might exist.

CHRONIC Rx

- Control of chronic diarrhea with loperamide should be one of the goals in a chronic malabsorptive state.
- Correction of volume and electrolyte disturbance with oral rehydration therapy should be made a priority.
- Bile acid conjugates can decrease steatorrhea in some cases.

TABLE 3 Malabsorptive Diseases or Conditions in Which Noninvasive Tests Can Establish Malabsorption or Provide a Diagnosis

Disease or Condition	Diagnostic Test(s)	Comment(s)
Lactose malabsorption	Lactose hydrogen breath test Lactose tolerance test	Tests do not differentiate between primary and secondary lactose malabsorption.
Incomplete fructose absorption	Fructose hydrogen breath test	
SIBO	^{14}C-D-xylose breath test Glucose hydrogen breath test Schilling test with and without antibiotics	A predisposing factor should be sought if the result of any of the tests is positive.
Bile acid malabsorption	SeHCAT test, ^{14}C-TCA test	Does not differentiate between primary and secondary causes.
Exocrine pancreatic insufficiency	Quantitative fecal fat determination	Used to establish malabsorption in chronic pancreatitis.
	Fecal elastase or chymotrypsin, tubeless tests	Variable sensitivity and specificity, depending on the type of test and stage of the disease.
Vitamin B_{12} malabsorption	Schilling test	The test is performed without intrinsic factor and, depending on the result with intrinsic factor, with antibiotics or pancreatic enzymes. Further tests are necessary if SIBO, terminal ileal disease, or pancreatic disease is suspected.

SeHCAT, Selenium-75-homotaurocholic acid test; *SIBO,* small intestinal bacterial overgrowth; *TCA,* taurocholic acid.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

TABLE 4 Useful Laboratory Tests for Patients with Suspected Malabsorption and for Establishing Possible Nutrient Deficiencies

Test	Comment(s)
Blood Cell Count	
Hematocrit, hemoglobin	Decreased in iron, vitamin B_{12}, and folate malabsorption or with blood loss
Mean corpuscular hemoglobin or mean corpuscular volume	Decreased in iron malabsorption; increased in folate and vitamin B_{12} malabsorption
White blood cells, differential	Decreased in vitamin B_{12} and folate malabsorption; low lymphocyte count in lymphangiectasia
Biochemical Tests (Serum)	
TGs	Decreased in severe fat malabsorption
Cholesterol	Decreased in bile acid malabsorption or severe fat malabsorption
Albumin	Decreased in severe malnutrition, lymphangiectasia, protein-losing enteropathy
Alkaline phosphatase	Increased in calcium and vitamin D malabsorption (severe steatorrhea); decreased in zinc deficiency
Calcium, phosphorus, magnesium	Decreased in extensive small intestinal mucosal disease, after extensive intestinal resection, or in vitamin D deficiency
Zinc	Decreased in extensive small intestinal mucosal disease or intestinal resection
Iron, ferritin	Decreased in celiac disease, in other extensive small intestinal mucosal diseases, and with chronic blood loss
Other Serum Tests	
Prothrombin time	Prolonged in vitamin K malabsorption
β-Carotene	Decreased in fat malabsorption from hepatobiliary or intestinal diseases
Immunoglobulins	Decreased in lymphangiectasia, diffuse lymphoma
Folic acid	Decreased in extensive small intestinal mucosal diseases, with anticonvulsant use, in pregnancy; may be increased in SIBO
Vitamin B_{12}	Decreased after gastrectomy, in pernicious anemia, terminal ileal disease, SIBO, and infection with *Diphyllobothrium latum*
Methylmalonic acid	Markedly elevated in vitamin B_{12} deficiency
Homocysteine	Markedly elevated in vitamin B_{12} or folate deficiency
Citrulline	May be decreased in destructive small intestinal mucosal disease or intestinal resection
Stool Tests	
Fat	Qualitative or quantitative increase in fat malabsorption
Elastase, chymotrypsin	Decreased concentrations and output in exocrine pancreatic insufficiency
pH	Less than 5.5 in carbohydrate malabsorption

SIBO, Small intestinal bacterial overgrowth; *TGs,* thyroglobulins.
From Feldman M et al: *Sleisenger and Fordtran's gastrointestinal and liver disease*, ed 10, Philadelphia, 2016, Elsevier.

- Pancreatic insufficiency is typically treated with a low-fat diet and exogenous pancreatic enzymes.
- Teduglutide-homolog of GLP-2 has been shown to increase absorptive surface area in short bowel syndrome.
- Periodic DEXA scans are indicated in chronic malabsorption in the setting of vitamin D deficiency.
- Oral supplementation with vitamins and minerals is important, sometimes requiring parenteral therapy.

REFERRAL

- Gastroenterology consultation can help in diagnosis when initial laboratory testing is unclear.
- Nutrition consultation can help patients with diet modification to alleviate symptoms.

PEARLS & CONSIDERATIONS

COMMENTS

- Malabsorption should be considered a sign of an underlying disease.
- Treatment should focus on treating the underlying disorder.
- Nutrient and volume repletion should be priority in any treatment plan of malabsorption.

BASIC INFORMATION

DEFINITION

Malaria is a protozoan disease caused by intraerythrocytic protozoa of the genus *Plasmodium* and transmitted by female *Anopheles* spp. mosquitoes. It is endemic throughout most of the tropics and is characterized by hectic fever and often presents with classic malarial paroxysm. Five species of genus *Plasmodium* usually infect humans (Table 1):

- *P. falciparum*
- *P. vivax*
- *P. malariae*
- *P. ovale*
- *P. knowlesi*

SYNONYMS

Periodic fever
Tertian malaria
Quartan malaria
Tropical splenomegaly

ICD-10CM CODES

B50.9	*Plasmodium falciparum* malaria, unspecified
B51.9	*Plasmodium vivax* malaria without complications
B52.9	*Plasmodium malariae* malaria without complications
B53.0	*Plasmodium ovale* malaria
B53.8	Other parasitologically confirmed malaria, not elsewhere classified
B54	Unspecified malaria

EPIDEMIOLOGY & DEMOGRAPHICS

Global:

- ~217 million cases in 2017 in more than 100 countries
- Approximately 435,000 deaths in 2017, with more than 80% of the deaths occurring in children of sub-Saharan Africa
- Three billion people live in malaria-endemic areas

U.S.:

- ~2078 cases reported to the CDC in the U.S. in 2017 (Fig. E1). In the majority of reported cases, U.S. civilians who acquired infection abroad had not adhered to a chemoprophylaxis regimen that was appropriate for the country in which they acquired malaria

More than 50% of the reported cases in the U.S. are *P. falciparum.* On average, there are six deaths per yr in the U.S.

- Most infections limited to:
  1. Immigrant population
  2. Returned travelers or troops from endemic area
- Occasionally, transmission through exposure to infected blood product or shared intravenous needles by users of injection drugs
- Congenital transmission possible
- Local mosquito-borne transmission reported
- Competent mosquito vectors present
  1. *A. albimanus* in Eastern U.S.
  2. *A. freeborni* in Western U.S.

Geographic distribution:

- *P. falciparum:* Sub-Saharan Africa, Papua New Guinea, Solomon Islands, Haiti, Indian subcontinent
- *P. vivax:* Central America, South America, North Africa, Middle East, Indian subcontinent
- *P. ovale:* West Africa
- *P. malariae:* Worldwide
- *P. knowlesi:* Southeast Asia

Parasite life cycle (Fig. E2):

- Human infection begins when a female anopheline mosquito bites (only female anopheline mosquito takes blood meal) and inoculates plasmodial sporozoites into bloodstream. The bite usually occurs between dusk and dawn.
- The sporozoites then travel to liver and invade to hepatocytes.
- In the hepatocytes, the sporozoites mature to tissue schizonts or become dormant hypnozoites.
- The tissue schizonts amplify the infection by producing a large number of merozoites (10,000 to 30,000).
- Each merozoite is capable of invading a RBC and can establish the asexual cycle of replication in RBCs.
- Asexual cycles produce and release 24 to 32 merozoites at the end of 48- or 72-hr *(P. malariae)* cycles.
- The hypnozoites are only found in relapsing malaria P. vivax or P. ovale and may remain dormant for up to 5 yr.
- Eventually some intraerythrocytic parasites develop into gametocytes. Male and female gametocytes are taken up by a female anopheline mosquito with a blood meal where they fertilize in the mosquito gut to produce a diploid zygote that matures to an ookinete; haploid sporozoites are generated that migrate to the salivary gland of the mosquito to infect another human.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Fever is the hallmark of malaria, known as malarial paroxysm, initially daily until synchronization of infection after several wk, when fever may occur every other day (tertian) in *P. vivax, P. ovale,* or *P. falciparum* malaria or every third day (quartan) in *P. malariae* malaria. Table 2 describes the WHO criteria for severe malaria.
- Classic malarial paroxysm characterized by:
  1. Cold stage: Abrupt onset of cold feeling associated with rigors, shakes
  2. Hot stage: High fever (~40° C; 104° F) associated with restlessness
  3. Sweating stage: Patient defervesces
- Nonspecific symptoms are:
  1. Headache
  2. Cough
  3. Myalgia
  4. Vomiting
  5. Diarrhea
  6. Jaundice
- *P. falciparum:*
  1. Most pathogenic of the four species.
  2. Rapidly progresses to high-level parasitemia.
  3. Important cause of the fatal malaria.

TABLE 1 Characteristics of the *Plasmodium* Species Responsible for Human Malaria

Characteristic	Species				
	P. falciparum	***P. vivax***	***P. ovale***	***P. malariae***	***P. knowlesi***
Incubation period in days (range)	12 (8-25)	14 (8-27)	17 (15 to ≥18)	28 (15 to ≥40)	11 (9 to >12)
Periodicity of febrile attacks (hours)	None	48	48	72	24
Earliest appearance of gametocytes (days)	10	3	?	?	?
Relapse	No	Yes	Yes	No	No
Duration of untreated infection (yrs)	1-2	1.5-4	1.5-4	3-50	?
RBC preference	Younger cells (but can invade cells of all ages)	Reticulocytes	Reticulocytes	Older cells	?
Characteristic morphology	Ring forms	Schüffner dots	Schüffner dots	Normal-sized cells	Ring forms
	Multiply infected cells	Enlarged RBCs	Enlarged RBCs	Band or rectangular forms of trophozoites	Occasional multiply infected cells
	Banana-shaped gametocytes				Band forms

RBC, Red blood cell.
From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

TABLE 2 World Health Organization Criteria for Severe Malaria, 2000

Impaired consciousness
Prostration
Respiratory distress
Multiple seizures
Jaundice
Hemoglobinuria
Abnormal bleeding
Severe anemia
Circulatory collapse
Pulmonary edema

From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, WB Saunders.

4. Classic malarial paroxysm is usually absent.
5. Incubation period after exposure is 12 days (range: 9 to 60 days).
6. Cytoadherence and resetting of RBCs play central role in pathogenesis.
7. The sequestration of RBCs in vital organs leads to fatal complications.
8. Cerebral malaria is a feared complication.
9. Invades erythrocytes of all ages.
10. Lacks hypnozoites (intrahepatic stage), does not relapse.
11. Blood smear usually shows ring form only.
12. Pigment color is black.
13. Banana-shaped gametocytes; if seen in blood, smear is diagnostic.
14. Chloroquine resistance is widely present.

- *P. vivax:*
  1. Known as tertian malaria: Fever occurs every other day.
  2. Duffy blood-group antigen FYA- or FYB-related receptor is needed for attachment to RBC.
  3. FyFy phenotype (most West African) individuals are resistant to *P. vivax* malaria.
  4. Incubation period after exposure is 14 days (range: 8 to 27 days).
  5. Hypnozoites may cause relapse of infection after yrs.
  6. Infects mainly reticulocytes.
  7. Irregularly shaped large rings and trophozoites, enlarged RBCs, and Schüffner dots are seen in peripheral blood smear.
  8. Pigment color is yellow-brown.
  9. *P. vivax* from Papua New Guinea has reduced sensitivity to chloroquine.
  10. Primaquine is needed to eradicate the hypnozoites.
- *P. ovale:*
  1. Also known as tertian malaria; fever occurs every other day.
  2. Occurs mainly in tropical Africa.
  3. Incubation period after exposure is 14 days (range: 8 to 27 days).
  4. Hypnozoites may cause relapse of infection.
  5. Infects mainly reticulocytes.
  6. Infected RBC is seen as enlarged, oval shape containing large ring or trophozoites with Schüffner dots.
  7. Pigment color is dark brown.
  8. Primaquine needed to eradicate the hypnozoites.
  9. No chloroquine resistance has been encountered.
- *P. malariae:*
  1. Known as quartan malaria; fever occurs every third day.
  2. Common cause of chronic malarial infection.
  3. May persist for 20 to 30 yr after leaving the endemic area.
  4. Worldwide distribution.
  5. Incubation period after exposure is 30 days (range: 16 to 60 days).
  6. Lacks hypnozoites (intrahepatic stage).
  7. May persist in blood for many yrs if treated inadequately.
  8. Chronic infection may cause soluble immune-complex, resulting in nephritic syndrome.
  9. Infects mainly mature RBCs.
  10. Band or rectangular forms of trophozoites are commonly seen in peripheral blood smear.
  11. Pigment color is brown-black.
- Cerebral malaria:
  1. Feared complication of *P. falciparum* infection.
  2. Mortality is ~20%.
  3. Pathogenesis is poorly understood.
  4. Ischemia as a result of sequestration of parasites or cytokines induced by parasite toxin(s) is the key debate.
  5. Seizure and altered mental status leading to coma are cardinal manifestation.
  6. Hypoglycemia, lactic acidosis, and elevated circulating tumor necrosis factor alpha (TNF-a) may be present.
  7. CSF studies: No increase of WBC count or protein, raised lactate concentrate, and increased opening pressure, especially in children, may be present.

Dx DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Typhoid fever
- Dengue fever
- Yellow fever
- Viral hepatitis
- Influenza
- Brucellosis
- Urinary tract infection
- Leishmaniasis
- Trypanosomiasis
- Rickettsial diseases
- Leptospirosis

WORKUP

- Clinical diagnosis is notoriously inaccurate.
- Demonstration of malarial parasites in blood smear is essential.
- Newer molecular diagnostic techniques (polymerase chain reaction, rapid diagnostic tests) are promising (Table 3).

LABORATORY TESTS

- The thick and thin blood film is required to identify malarial parasites (Fig. E3). A Giemsa-stained film of the patient's peripheral blood should be examined for parasites as soon as possible.
- The thick smears are more sensitive and primarily used to detect the presence of parasites.
- The thin smears are used for species differentiation and parasite density estimation.
- A patient who is suspected of having malaria but who has no parasite seen in blood smears should have blood smears repeated every 12 to 24 hr for 3 consecutive days.

PREPARATION OF BLOOD SMEAR:

- Must be prepared from fresh blood obtained by pricking the finger.
- The thin smear is fixed in methanol before staining.
- The thick smear is stained unfixed.
- The smear should be stained with a 3% Giemsa solution (pH of 7.2) for 30 to 45 min.
- The parasite density should be estimated by counting the percentage of RBCs infected, not the number of parasites, under an oil immersion lens on thin film.

COMMON ERRORS IN READING MALARIAL SMEARS:

- Platelets overlying an RBC
- Misreading artifacts as parasites
- Concern about missing a positive slide

MOLECULAR DIAGNOSIS OF MALARIA:

- Rapid diagnostic tests (RDT):
  1. Employ immunochromatographic lateral flow technology for antigen detection.
  2. Thus far only one RDT has been FDA approved: BinaxNOW Malaria test kit.
  3. This kit is based on antigens histidine-rich protein-2 (HRP-2) and aldolase.
  4. For *P. falciparum:* Sensitivity 95% and specificity 94%.
  5. For *P. vivax:* Sensitivity 69% and specificity 100%.
- Limitations of the BinaxNOW Malaria test:
  1. Not approved for mixed infections.
  2. Should not be used for *P. malariae* and *P. ovale* as data are limited.
  3. Positive test must be confirmed by microscopy.
  4. Negative results require confirmation by thick and thin smears.
  5. This test cannot be used to monitor therapy as antigen persists after the elimination of the parasite, causing false positives.
- Other diagnostic tests available include:
  1. Tagged monoclonal antibodies for malaria antigen detection.
  2. Nucleic acid amplification and detection: polymerase chain reaction (PCR) can detect parasites down to a level of one to five parasites per microliter of blood. PCR can detect mixed species infection and is now considered the gold standard for diagnosis.
  3. Fluorescence microscopy with acridine orange or other staining.
  4. Dark field microscopy.

TABLE 3 Malaria Rapid Diagnostic Tests Available in the U.S.[a]

RDT Name	Malaria Antigen Target	Malaria Species Detected	Sensitivity	Comment
BinaxNOW	HRP-2 and aldolase	*P. falciparum, P. vivax, P. malariae,* and *P. ovale*	94% for *P. falciparum* 84% for non-*P. falciparum* 87% for pure *P. vivax* infections 62% for pure *P. ovale* and *P. malariae* infections	Sensitivity increased to 96% for pure *P. falciparum* infection Overall specificity of 99% FDA-approved for use in the U.S.
ParaSight F	HRP-2	*P. falciparum*	96.5-100 in Kenya when >60 parasites/μL, lower with less parasitemia 40% in travelers when <50 parasites/μL, >93% when >100 parasites/μL	Antigen persists for 6-7 days 6 in 11.9%-20% of subjects whose blood smears had cleared Not FDA approved for use in the U.S.
ICT Malaria Pf/Pv	HRP-2 and aldolase	*P. falciparum* and *P. vivax*	97% for *P. falciparum* 44% for *P. vivax*	Specificity of 90% for *P. falciparum* Specificity of 100% for *P. vivax* Not FDA-approved for use in the U.S.
OptiMAL-IT	LDH	*P. falciparum, P. vivax, P. malariae,* and *P. ovale*	85-95%; decreased with lower parasite density	Specificity of 100% *P. falciparum*, 75%-85% for *P. vivax* Not FDA approved for use in the U.S.
Clearview	LDH	*P. falciparum, P. vivax, P. malariae,* and *P. ovale*	93% specificity of 100%, with sensitivities of 99%, 90.0%, 86%, and 60%, respectively, for *P. falciparum, P. vivax, P. malariae,* and *P. ovale*	Specificity of 100% for *P. falciparum*, 99% for *P. vivax*, 90% for *P. malariae*, and 60% for *P. ovale* Not FDA-approved for use in the U.S.

FDA, Food and Drug Administration; *HRP-2,* histidine-rich protein-2; *ICT,* immunochromatographic diagnostic test; *LDT,* laboratory developed test; *RDT,* rapid diagnostic test.
[a]Direct microscopy should be performed where available with a negative RDT, given higher false-negative rates with low parasitemia, and when severe malaria is suspected.
From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

ANTIMOSQUITO MEASURES:

- Eradication of mosquito breeding places by chemical spray
- Use of mosquito nets properly in the endemic areas
- Use of protective clothing
- Use of insect spray (permethrin), mosquito coils, or repellents such as diethyltoluamide (DEET). For adults, DEET (30% to 50%) is generally protective for at least 4 hr. For smaller children, use DEET at ≤20% concentration

ACUTE GENERAL Rx

A definitive diagnosis of malaria is essential for specific antimalarial chemotherapy.

UNCOMPLICATED CHLOROQUINE-SENSITIVE PLASMODIUM VIVAX, PLASMODIUM OVALE, OR PLASMODIUM MALARIAE (NON-FALCIPARUM MALARIA):

- Chloroquine:
  1. Adults: 600 mg base (= 1000 mg salt) orally immediately, followed by 300 mg base (= 500 mg salt) orally at 6, 24, and 48 hrs.
  2. Children: 10 mg base/kg orally immediately, followed by 5 mg base/kg orally at 6, 24, and 48 hrs.
  3. Maximum total dose: 1500 mg base (= 2500 mg salt).
  4. An alternative agent is hydroxychloroquine (Plaquenil): 620 mg base (= 800 mg salt) orally immediately, followed by 310 mg base (= 400 mg salt) orally at 6, 24, and 48 hrs.
- In the case of *P. vivax* and *P. ovale,* treatment with primaquine 15 mg daily for 14 days is needed to eradicate the exoerythrocytic forms, especially the hypnozoites responsible for relapses.
- G6PD should be measured before primaquine is given. Primaquine is not recommended for those who are glucose-6-phosphate dehydrogenase deficient, because primaquine can cause hemolysis and even death in G6PD-deficient persons. Normal G6PD levels must be documented before using primaquine for either chemoprophylaxis or treatment.
- Chloroquine-resistant *P. vivax* has been documented; in that case use quinine sulfate (10 mg/kg) plus either tetracycline or doxycycline or clindamycin for 7 days.

UNCOMPLICATED FALCIPARUM MALARIA OR SPECIES NOT IDENTIFIED:

- Chloroquine can be used cautiously for falciparum malaria acquired in chloroquine-sensitive areas (chloroquine is more rapidly effective than quinine).
- For uncomplicated *P. falciparum,* an oral artemisinin combination therapy (ACT), is recommended by the CDC as the first-line agent. While there are numerous ACT combinations, the only ACT approved in the U.S. is artemether-lumefantrine (Coartem), which is not widely available. Do not delay therapy in trying to obtain it; use another first-line agent. Dosage for adults: 4 tablets artemether-lumefantrine (20/120 mg) as a single dose, then 4 tablets again after 8 hr, then 4 tablets q12h for 2 days (take with food). Can cause prolongation of QT interval. Not recommended in infants <5 kg. Dose dependent on weight in children:
  1. 5 to 15 kg: 1 tablet (20/120 mg) as a single dose, then 1 tablet again after 8 hr, then 1 tablet q12h for 2 days
  2. 16 to 25 kg: 2 tablets (40/240 mg) as a single dose, then 2 tablets again after 8 hr, then 2 tablets q12h for 2 days
  3. 26 to 35 kg: 3 tablets (60/360 mg) as a single dose, then 3 tablets again after 8 hr, then 3 tablets q12h for 2 days
  4. >35 kg: Treat as adult
- Atovaquone-proguanil (Malarone): 250 mg atovaquone/100 mg proguanil): 4 adult tabs PO once a day for 3 days with food. Pediatric dosage: Pediatric tablets (62.5 mg atovaquone/25 mg proguanil) are used based on weight:
  1. 5 to 8 kg: 2 pediatric tabs PO once daily for 3 days
  2. 9 to 10 kg: 3 pediatric tabs PO once daily for 3 days
  3. 11 to 20 kg: 1 adult tab PO once daily for 3 days
  4. 21 to 30 kg: 2 adult tabs PO once daily for 3 days
  5. 31 to 40 kg: 3 adult tabs PO once daily for 3 days
  6. >40 kg: 4 adult tabs PO once daily for 3 days
- Another first-line option for treatment in adults is oral quinine sulfate 10 mg (salt)/kg (usually 650 mg) q8h for 3 to 7 days plus doxycycline 100 mg PO bid, both for 7 days. Pediatric dosage: Quinine sulfate 10 mg/kg PO tid plus clindamycin 20 mg/kg per day divided tid, both for 7 days.
- Table 4 summarizes some treatment guidelines for severe *Plasmodium falciparum* malaria.

ALTERNATIVES:

- Quinine sulfate plus clindamycin 900 mg tid for 7 days in adults
- Mefloquine 750 mg PO, then 500 mg PO 6 to 12 hr later in adults

TABLE 4 Treatment Guidelines for Severe *Plasmodium falciparum* Malaria

Drug	Dose	Comments
Artemisinin compounds		
Artesunate Artemether	2.4 mg/kg IV bolus at 0, 12, 24 hours, then daily until patient is able to transition to the following oral regimen: 1. Artemether + lumefantrine: Tablets containing 20 + 120 mg, 40 + 240 mg of artemether and lumefantrine, respectively • Adults ≥35 kg: 80 + 480 mg twice daily for 3 days • Children: • 5 to <15 kg: 20 + 120 mg twice daily for 3 days • 15 to <25 kg: 40 + 240 mg twice daily for 3 days • 25 to <35 kg: 60 + 360 mg twice daily for 3 days 2. Artesunate + amodiaquine: A fixed-dose combination tablet containing 25 + 67.5 mg, 50 + 135 mg, 100 + 270 mg of artesunate and amodiaquine, respectively • Adults ≥36 kg, 200 + 540 mg daily for 3 days • Children: • 4.5 to <9 kg: 25 + 67.5 mg daily for 3 days • 9 to <18 kg: 50 + 135 mg daily for 3 days • 18 to <36 kg: 100 + 270 mg daily for 3 days 3. Dihydroartemisinin (DHA) + piperaquine (PPQ): Tablets containing 20 + 160 mg, 40 + 320 mg of DHA and PPQ, respectively • Adults: • 36 to <75 kg: 120 + 960 mg daily for 3 days • ≥75 kg: 160 + 1280 mg daily for 3 days (no data on dose recommendation >100 kg) • Children • 5 to <7 kg: 10 + 80 mg daily for 3 days • 7 to <13 kg: 20 + 160 mg daily for 3 days • 13 to <24 kg: 40 + 320 mg daily for 3 days • 24 to <36 kg: 80 + 640 mg daily for 3 days 4. Artesunate or quinine PO to complete 7 days plus doxycycline, 100 mg PO bid × 7 days 5. Artesunate or quinine PO to complete 7 days plus clindamycin, 20 mg base/kg/d PO, tid × 7 days Initial dose: 3.2 mg/kg IM (anterior tight); maintenance dose: 1.6 mg/kg IM daily until patient is able to transition to oral regimen as described earlier for artesunate	Artesunate has "investigational new drug" status in the U.S. and is available only on request to the CDC (770-488-7788). Eligibility requirements include inability to take oral medications, high levels of parasitemia, clinical evidence of severe malaria, intolerance of or contraindication to quinidine, failure of quinidine therapy, and lack of rapid access to quinidine. Where available, artesunate rectal suppositories (10 mg/kg) may be used in children <5 yr of age if IV or IM administration is not possible. Doxycycline is contraindicated in children <8 yr of age and in pregnancy. Atovaquone/proguanil is packaged in the U.S. in fixed-dose combination tablets of 250 mg atovaquone/100 mg proguanil for adults and 62.5 mg atovaquone/25 mg proguanil for children. Safety of atovaquone/proguanil in pregnancy has not been established.
Cinchona Alkaloid Regimens		
Quinine dihydrochloride	20 mg salt/kg IV or IM on admission, then 10 mg/kg q8h. Can be given IM if IV administration is not possible. One of the following drugs should also be given concurrently: 1. ACT as listed earlier. 2. Doxycycline as listed earlier. If patient unable to take PO, give 100 mg IV q12h and switch to PO when possible. Avoid rapid IV administration. 3. Clindamycin as listed earlier. If patient unable to take PO, give 10 mg base/kg loading dose IV followed by 5 mg base/kg IV q8h and switch to PO when possible. Avoid rapid IV administration.	The infusion rate of IV quinine should be rate controlled and not exceed 5 mg salt/kg per hour. The drug is usually diluted in 5% dextrose and infused over 4 hours. IV quinine is not available in the U.S. When administering IM, the dose should be split and diluted to a concentration of 60-100 mg/kg and delivered to each thigh. Reduce the quinine dose by one third (to 10 mg salt/kg q12h) after 48 hours in patients with severe renal and/or hepatic dysfunction. Doxycycline is contraindicated in children <8 yr old and in pregnancy.
Quinidine gluconate	6.25 mg base/kg (= 10 mg salt/kg) IV on admission over 1-2 hours, then 0.0125 mg base/kg minute (= 0.02 mg salt/kg per minute) continuous infusion. An alternative regimen is 15 mg base/kg (= 24 mg salt/kg) loading dose IV infused over 4 hours, followed by 7.5 mg base/kg (= 12 mg salt/kg) infused over 4 hours q8h, starting 8 hours after the loading dose. A second drug should be given concurrently as listed earlier for quinine.	The loading dose should be omitted if the patient received >40 mg/kg quinine in the preceding 48 hours or mefloquine in the previous 12 hours. Reduce the dose by one third after 48 hours in patients with severe renal and/or hepatic dysfunction.

ACT, Artemisinin combination therapy; *bid,* twice a day; *CDC,* Centers for Disease Control and Prevention; *IM,* intramuscular; *IV,* intravenous; *PO,* by mouth; *q8h,* every 8 hours; *tid,* thrice a day.
(From Vincent JL et al: *Textbook of critical care*, ed 7, Philadelphia, 2017, Elsevier.)

- Atovaquone-proguanil (Malarone) or quinine sulfate plus doxycycline can be used when species is unknown. Artemether-lumefantrine is also recommended the World Health Organization (WHO) for treatment of unknown species, but in U.S. is only approved for *P.* falciparum
- Other ACT combinations not yet available in the U.S.: Artesunate-amodiaquine, artesunate-mefloquine, artesunate-sulfadoxine-pyrimethamine, dihydroartemisinin-piperaquine, artesunate-pyronaridine tetraphosphate.

NOTE: Parasitemia may paradoxically rise in the first 24 to 36 hr and is not an indication of treatment failure.

SEVERE FALCIPARUM MALARIA:

- It is a medical emergency; intensive care is preferred.
- Measurement of blood glucose, lactate, ABG is important.
- IV quinidine gluconate 10 mg salt/kg loading dose (maximum 600 mg) in normal saline (NS); infuse slowly over 1 to 2 hr, followed by continuous infusion of 0.02 mg/kg/min until patient can swallow.
- Need to monitor ECG for observation of QT interval as can prolong. Also need to monitor blood pressure and glucose to avoid hypoglycemia.
- Alternatively, IV artesunate: 2.4 mg/kg IV at hour 0, then at 12 and 24 hr followed by 2.4 mg/kg once daily. If <20 kg use 3.0 mg/kg per dose. This medication is not FDA approved but is available through the CDC. One recent study showed the superiority of parenteral artesunate over parenteral quinine in adults and children who could not take an oral medication.

TABLE 5 Drug Regimens Used for Prevention of Malaria

Drug	Adult Dosage	Pediatric Dosage	Comments
Chloroquine-Sensitive Areas			
Chloroquine phosphate (drug of choice)	500 mg salt (300 mg base) orally once/wk	8.3 mg/kg salt (5 mg/kg base) once/wk, up to adult dose of 300 mg base	Begin 1-2 wk before exposure, continue during exposure, and continue for 4 wk after exposure May be used in pregnant women
Hydroxychloroquine sulfate	400 mg salt (310 mg base) orally once/wk	6.5 mg/kg salt (5 mg/kg base) orally once/wk	Begin 1-2 wk before exposure, continue during exposure, and continue for 4 wk after exposure An alternative to chloroquine for use only in areas with chloroquine-sensitive malaria
Chloroquine-Resistant Areas			
Atovaquone-proguanil	250 mg/100 mg (1 tablet) daily	5-8 kg: Pediatric tablet daily 9-10 kg: Pediatric tablet daily 11-20 kg: 1 Pediatric tablet daily 21-30 kg: 2 Pediatric tablets daily 31-40 kg: 3 Pediatric tablets daily >40 kg: 1 Adult tablet daily	Begin 1-2 days before exposure, continue during exposure, and continue for 7 days after exposure Pediatric tablets contain 62.5 mg atovaquone and 25 mg proguanil hydrochloride See text for contraindications
Mefloquine	250 mg salt (228 mg base) orally once/wk	≤9 kg: 5 mg/kg salt (4.6 mg/kg base) orally once/wk 10-19 kg: Tablet orally once/wk 20-30 kg: Tablet orally once/wk 31-45 kg: Tablet orally once/wk >45 kg: 1 Tablet orally once/wk	Begin 1-2 wk before exposure, continue during exposure, and continue for 4 wk after exposure
Or			
Doxycycline	100 mg daily	2.2 mg/kg/day up to 100 mg/day	Begin 1-2 days before exposure, continue during exposure, and for 4 wk after exposure; not to be used in children >8 yr or pregnant women
Or			
Alternative			
Primaquine	52.6 mg salt (30 mg base) orally daily	0.8 mg/kg salt (0.5 mg/kg base) up to adult dose orally daily	Begin 1-2 days before exposure, continue during exposure, and continue for 7 days after exposure Contraindicated in people with G6PD deficiency, in pregnancy, and during lactation Prophylaxis to areas principally with *P. vivax*
Tafenoquine (Krintafel)	300 mg tab once		Prevention of relapse of *P. vivax* 300 mg once

(From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.)

- Plasmapheresis is an option for parasitemia >30% or in pregnant women and in elderly with severe malaria.

NOTE: WHO recommends IV artesunate as the treatment of choice for severe malaria in adults and children in area of low transmission. Data on children in high-transmission regions are limited, and WHO recommends treatment with artesunate, artemether, or quinine.

MULTIDRUG-RESISTANT MALARIA:

- Mefloquine 1250 mg as a single dose, *or*
- Halofantrine 500 mg every 6 hr for 3 doses, repeat same course after 1 wk
- Combination therapy usually preferred

DISPOSITION

RISK FACTORS FOR FATAL MALARIA:

- Failure to take chemoprophylaxis
- Delay in seeking medical care
- Misdiagnosis

COMPLICATIONS OF MALARIA:

- Anemia
- Acidosis
- Hypoglycemia
- Respiratory distress
- Disseminated intravascular coagulation
- Blackwater fever
- Renal failure
- Shock

REFERRAL

- To an infectious disease specialist or travel medicine expert for severe malaria complications
- To an intensive care specialist if severe cerebral malaria or other major organ failure develops
- All malaria cases are mandated to be reported to local and state health departments by health care providers or laboratory staff

PEARLS & CONSIDERATIONS

HOST RESPONSE

- The specific immune response to malaria confers protection from high-level parasitemia and disease, but not from infection.
- Asymptomatic parasitemia without illness (premunition) is common among adults in endemic areas.
- Immunity is specific for both the species and the strain of infecting malarial parasites.
- Immunity to all strains is never achieved.
- Normal spleen function is an important host factor because of immunologic as well as filtering functions of the spleen.
- Both humoral and cellular immunity is necessary for protection.
- Polyclonal increase in serum level of immunoglobulin G (IgG), IgM, and IgA occurs in immune individuals.
- Antibody to antigenically variant protein PfEMP1 is important for protection in case of *P. falciparum* malaria.
- Passively transferred IgG from immune individuals has been shown to be protective.
- Maternal antibody confers relative protection of infants from severe disease.
- Genetic disorders (sickle cell disease, thalassemia, and G6PD deficiency) confer protection from death because parasites are unable to grow efficiently in low-oxygen tensions, thus preventing high-level parasitemias.
- Individuals deficient of Duffy factor in RBCs are resistant to infection by *P. vivax.*
- Nonspecific defense mechanisms, such as cytokines (TNF-α, IL-1, -6, -8), also play an important role in protection, causing fever (temperatures of 40° C damage mature parasites) and other pathologic effects.

PREVENTION OF MALARIA: Medications are available for the prophylaxis of malaria and will vary depending on level of chloroquine resistance in a given area (Table 5).

Areas free of chloroquine-resistant Falciparum malaria

Chloroquine 300 mg base (500 mg chloroquine phosphate) PO/wk. Start 1 wk prior to

*These numbers are intended for health care professionals only.
From Cullen KA et al: Malaria surveillance—United States, 2013, *MMWR Surveill Summ* 65:1-22, 2016.

arrival in malaria area, then weekly while there and for 4 wk on leaving malaria area. Pediatric dose: 8.3 mg/kg (5 mg/kg base). Alternatives for adults include atovaquone-proguanil (Malarone): 1 adult tablet per day starting 1 to 2 days prior to arriving in malaria area, then daily while there and then for 7 days daily on leaving malaria area. For children, atovaquone-proguanil pediatric tablets based on weight:

- 11 to 20 kg: 1 pediatric tablet
- 21 to 30 kg: 2 pediatric tablets
- 31 to 40 kg: 3 pediatric tablets
- 40 kg: 1 adult tablet

Areas with chloroquine-resistant Falciparum malaria

- Atovaquone-proguanil (Malarone): Dosing as previously
- Mefloquine 250 mg (228 mg base) PO/wk, starting 1 wk before arriving in malaria area, weekly while there and then weekly for 4 wk on return. In children, mefloquine dose is based on weight:
  1. <15 kg: 5 mg/kg
  2. 16 to 19 kg: ¼ adult dose
  3. 20 to 30 kg: ½ adult dose
  4. 31 to 45 kg: ¾ adult dose
  5. >45 kg: Adult dose
- Doxycycline 100 mg PO/day for adults and children aged >8. Start 1 to 2 days before travel, daily while in malaria area, and then daily for 4 wk on return.
- Tafenoquine (Arakoda, Krintafel) is a long-acting primaquine analog FDA approved in two different strengths for antiretroviral therapy (Krintafel) for P. vivax infection (300 mg single dose) and for chemoprophylaxis (Arakoda): Loading dose is 200 mg once/day for 3 days. Maintenance dose is 200 mg once/wk starting 7 days after last loading dose, terminal dose is 200 mg once (7 days after last maintenance dose).

SPECIAL CONSIDERATIONS:

- Long-term visitors or travelers
- Children aged <12 yr
- Immunocompromised host
- Pregnant women: Chloroquine and mefloquine are safe in pregnancy but not atovaquone-proguanil. A recent trial revealed that the burden of malaria in pregnancy was significantly lower among adolescent girls or women who received intermittent preventive treatment with dihydroartemisinin-piperaquine than among those who received sulfadoxine-pyrimethamine, and monthly treatment with dihydroartemisinin-piperaquine was superior to three-dose dihydroartemisinin-piperaquine with regards to several outcomes.[1] Avoid doxycycline and primaquine.
- An increasing number of areas in southeast Asia have mefloquine-resistant malaria, including Cambodia, Thailand, and Vietnam. Therefore, in specific regions of these countries, mefloquine cannot be used for prophylaxis or treatment.

PREVENTION OF RELAPSE[2]:

- Treatment of *P. vivax* requires the clearing of asexual parasites, but relapse can be prevented only if dormant hypnozoites are cleared from the liver (a treatment termed "radical cure")
- Tafenoquine, slowly eliminated, single dose 8-aminoquinoline is effective in significantly lowering the risk of *P. vivax* recurrence in patients with phenotypically normal GG PD activity

VACCINATION:

- In 2015, Mosquirix (RTS,S), a recombinant protein-based vaccine, was approved in Europe to prevent malaria in babies in Africa. It showed an efficacy of about 30% in babies 6 to 12 wk old and about 46% in babies 5 to 17 mo old.
- New DNA-based vaccines are in development.

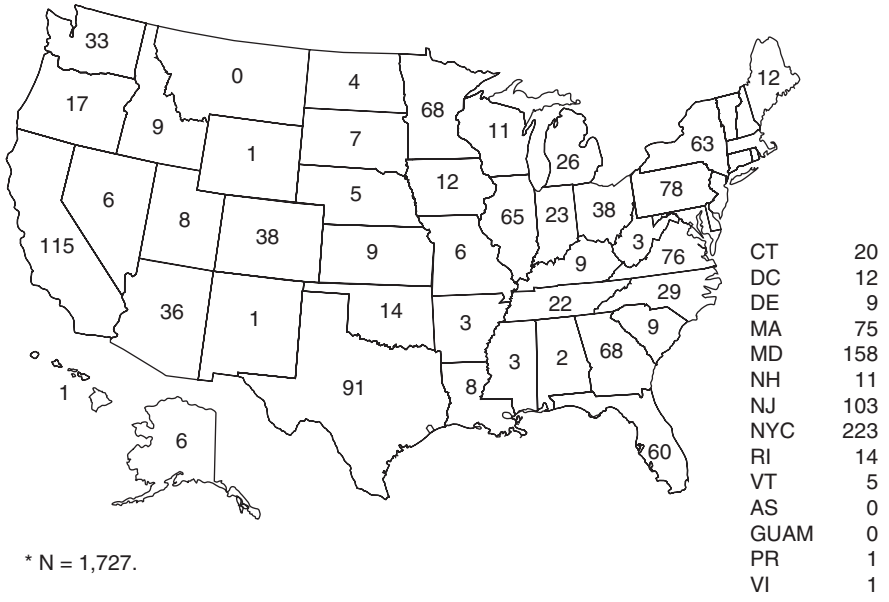

FIG. E1 Number of malaria cases, by state in which the disease was diagnosed—U.S., 2013. (Cullen KA et al: Malaria surveillance—United States, 2013, *MMWR Surveill Summ* 65:1-22, 2016.)

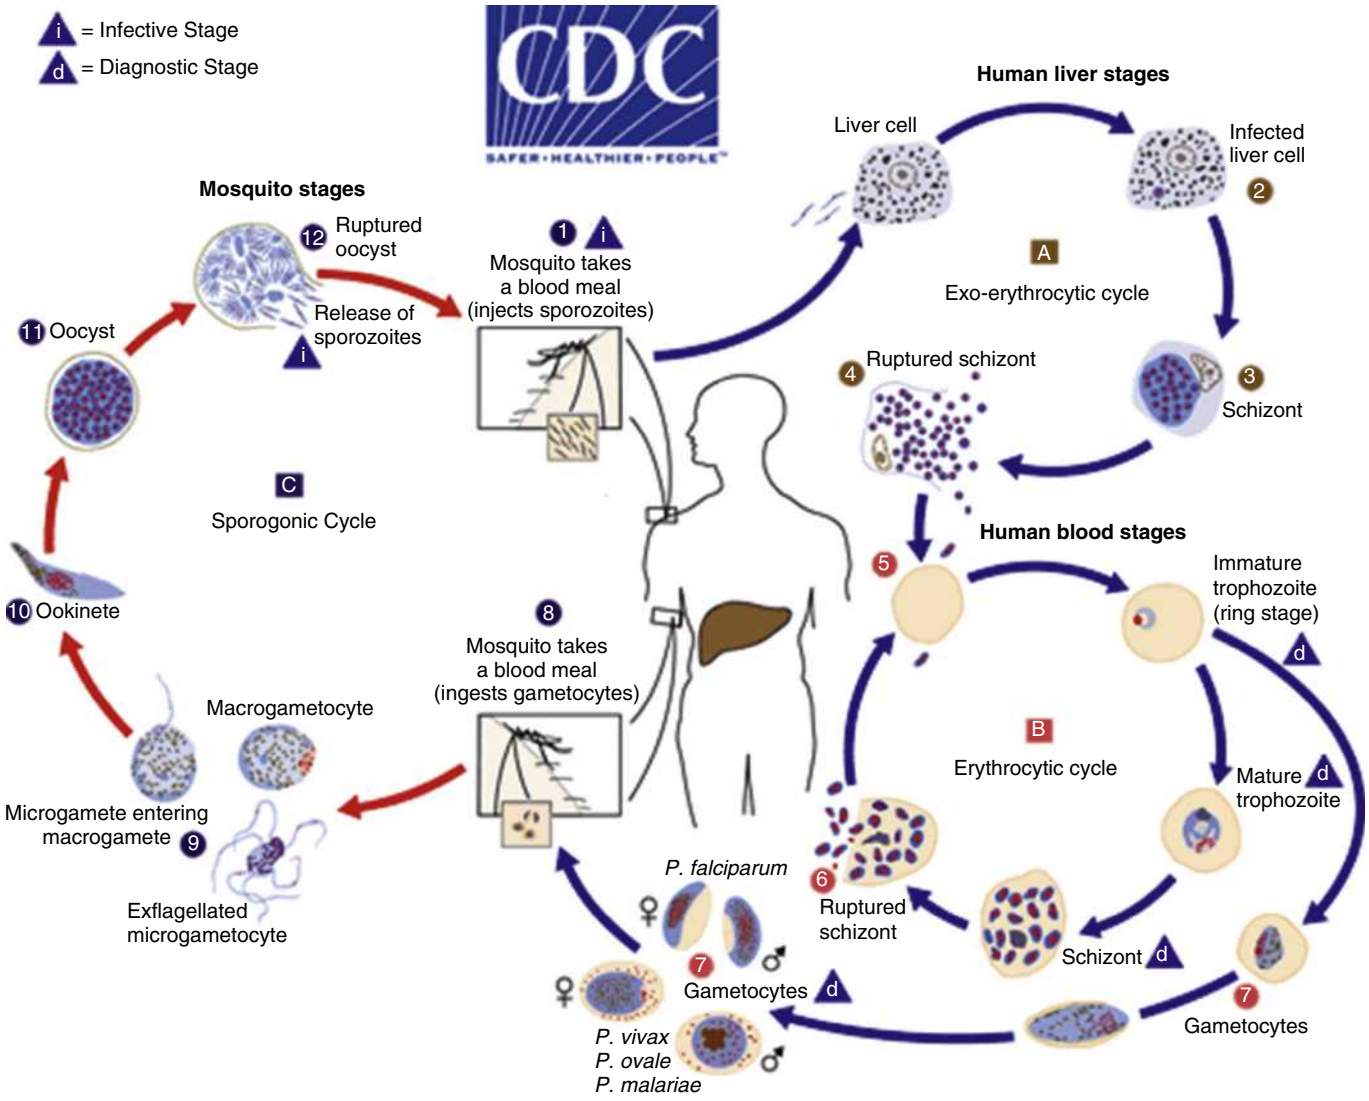

FIG. E2 Life cycle of human malaria parasites. The malaria parasite life cycle involves two hosts. During a blood meal, a malaria-infected female *Anopheles* mosquito inoculates sporozoites into the human host *(1).* Sporozoites infect liver cells *(2)* and mature into schizonts *(3),* which rupture and release merozoites *(4).* (Of note, in *P. vivax* and *P. ovale* a dormant stage [hypnozoites] can persist in the liver and cause relapses by invading the bloodstream weeks, or even years, later.) After this initial replication in the liver (exo-erythrocytic schizogony *[A]*), the parasites undergo asexual multiplication in the erythrocytes (erythrocytic schizogony *[B]*). Merozoites infect red blood cells *(5).* Ring stage trophozoites mature into schizonts, which rupture, releasing merozoites *(6).* Some parasites differentiate into sexual erythrocytic stages (gametocytes) *(7).* Blood stage parasites are responsible for clinical manifestations of the disease. The gametocytes, male (microgametocytes) and female (macrogametocytes), are ingested by an *Anopheles* mosquito during a blood meal *(8).* The parasites' multiplication in the mosquito is known as the sporogonic cycle *(C).* While in the mosquito's stomach, the microgametes penetrate the macrogametes, generating zygotes *(9).* The zygotes in turn become motile and elongated (ookinetes) *(10)* and invade the midgut wall of the mosquito, where they develop into oocysts *(11).* The oocysts grow, rupture, and release sporozoites *(12),* which make their way to the mosquito's salivary glands. Inoculation of the sporozoites *(1)* into a new human host perpetuates the malaria life cycle. (From Centers for Disease Control and Prevention. About Malaria: Biology; www.cdc.gov/malaria/about/biology/ in Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases*, ed 8, Philadelphia, 2019, Elsevier.)

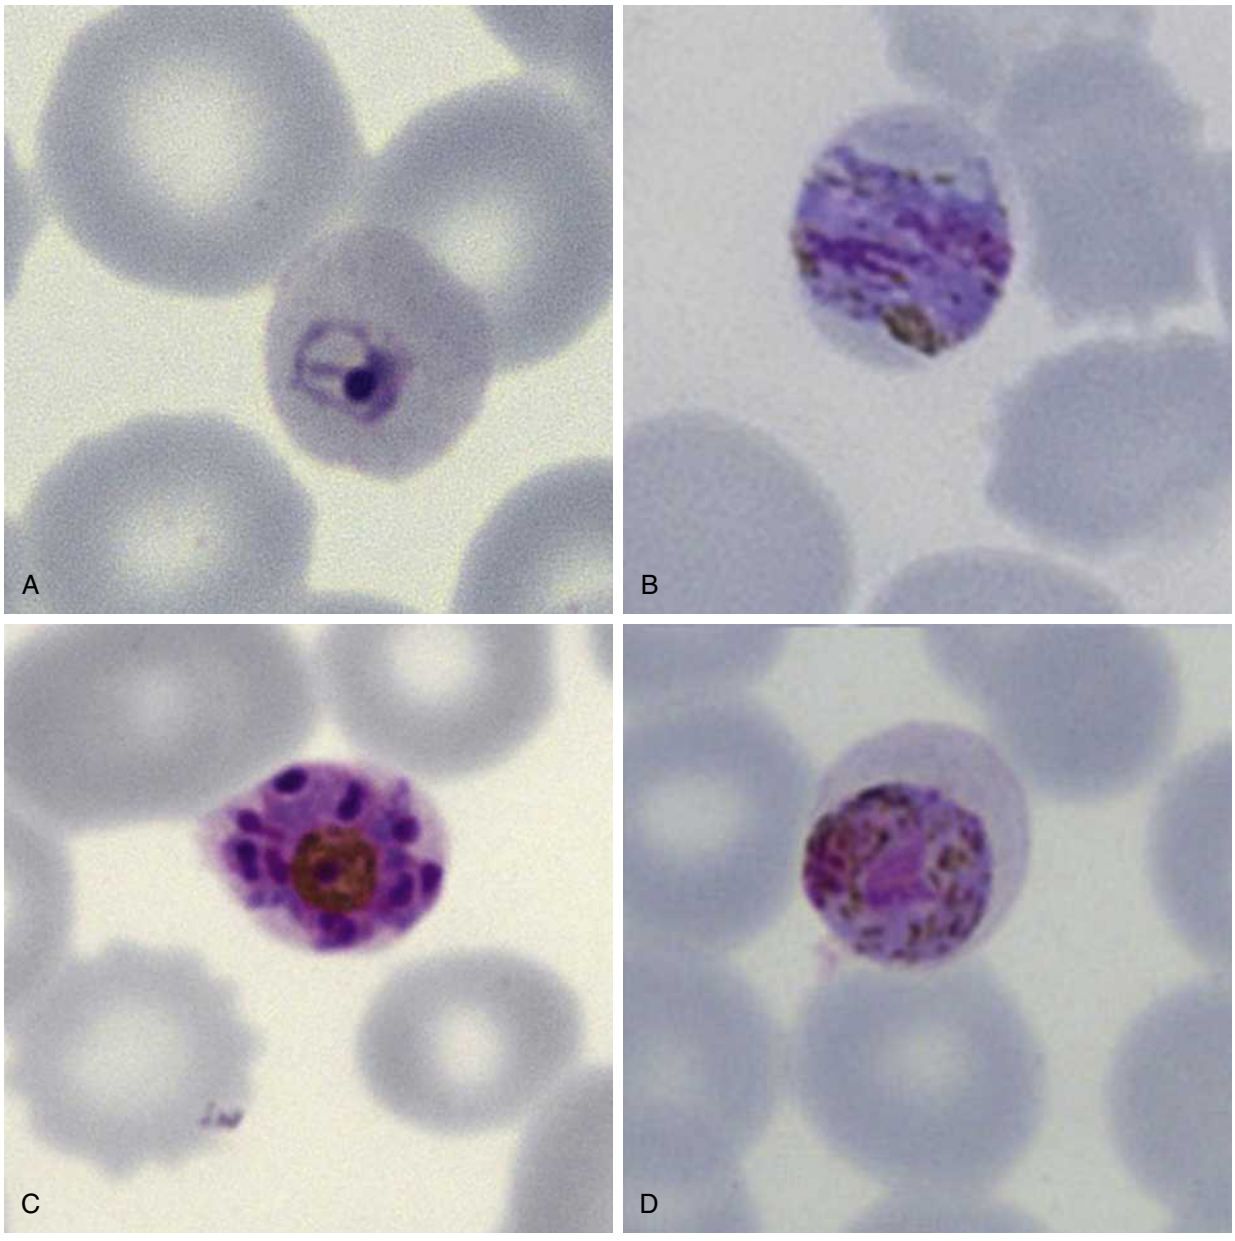

FIG. E3 Morphology of *P. malariae.* Early trophozoites **(A)** are small but less fine than those of *P. falciparum;* in this case the ring is irregular and the chromatin dot is within the main parasite cytoplasm. A late trophozoite **(B)** spans the erythrocyte as a thick "band form." A characteristic "daisy head" schizont **(C)** has eight merozoites arrayed around the central pigment. Finally, the gametocyte **(D)** is typically small and does not fill the normal-sized erythrocyte. (From Bain BJ et al: *Dacie and Lewis practical haematology*, ed 12, Philadelphia, 2017.)

BASIC INFORMATION

DEFINITION

Malignant hyperthermia (MH) is a rare life-threatening subclinical myopathy that can manifest clinical symptoms in MH-susceptible (MHS) individuals after exposure to triggering medications. These drugs include halogenated anesthetic gases, such as halothane, isoflurane, sevoflurane, and desflurane, as well as the depolarizing agent succinylcholine. When given to genetically susceptible individuals, these agents may cause excessive skeletal muscle contraction. Initial signs include rising end-tidal carbon dioxide ($ETCO_2$) levels and tachycardia, with subsequent hyperthermia, acidemia, and skeletal muscle rigidity. Symptomology may be variable, especially during surgery and general anesthesia. Mortality has recently been reported to be 1.4% to 5%, down from 70% in the past, likely due to the prevalence of intraoperative temperature and $ETCO_2$ monitoring and the use of dantrolene for treatment.

SYNONYMS

Anesthesia related hyperthermia
Hyperpyrexia, Malignant

Malignant Hyperpyrexia
MHS
MH

ICD-10CM CODES	
T88.3	Malignant hyperthermia due to anesthesia
T88.3XXA	initial encounter
T88.3XXD	subsequent encounter
T88.3XXS	sequelae

EPIDEMIOLOGY & DEMOGRAPHICS

Malignant hyperthermia results from excess calcium accumulation in the skeletal muscle tissue of MHS individuals following exposure to one or more "triggering" medications, including halogenated volatile anesthetics and the skeletal muscle relaxant, succinylcholine. This is due to excessive release of sarcoplasmic calcium, which occurs because of a genetic anomaly. The result is a hypermetabolic and prolonged contractile state, with subsequent serious morbidity and possible mortality, especially when untreated. A recent study comparing human muscle fiber mitochondria from non-MHS patients to those from MHS patients found that mitochondria from MHS patients displayed anatomic and physiologic differences when exposed to halothane, while the non-MHS fibers did not.

All ethnic groups are at risk. MH susceptibility is associated with, although distinct from, two other diseases, central core and multiminicore disease.

PREVALENCE: In the general population, between 1:2000 to 1:3000 are thought to carry a defective gene for the ryanodine receptor. However, the prevalence of MHS is estimated to be 1:2000. In family cohorts of patients who are susceptible, the prevalence of susceptibility ranges from 1:200 to 1:5000 due to incomplete penetrance and variable expressivity. The majority of these MHS individuals are never exposed to a triggering agent such that a MH clinical event following exposure occurs with a frequency between 1:15,000 to 1:75,000.

PREDOMINANT SEX AND AGE: MH male to female ratio is 2:1. Children account for up to half of cases.

PEAK INCIDENCE: Among patients undergoing general anesthesia, the incidence is approximately 1:100,000. It is widely believed that unrecognized events occur and that half of afflicted patients have had a prior uneventful exposure to a triggering agent.

RISK FACTORS:

- Preoperatively, the patient and family history is used to evaluate the risk of MH and other myopathies. Patients with other *RYR1* abnormalities, such as central core myopathy or multiminicore disease (*RYR1* or *SELENON*), though not true MHS, should not receive succinylcholine or volatile anesthetics.
- Patients with dystrophinopathies such as Duchenne and Becker muscular dystrophy, enzymopathies of skeletal muscle such as McArdle disease, or exercise- and heat-induced rhabdomyolysis, may develop rhabdomyolysis when exposed to these agents, especially succinylcholine.
  1. This pathophysiology, though different from that of MH, may result in similar signs such as hyperkalemia-induced peaked T waves on the ECG, along with acidosis.
  2. However, it is important to understand that dantrolene is unlikely to be of value in treating these causes of rhabdomyolysis.
  3. Osteogenesis imperfecta, myotonia, and neuroleptic malignant syndrome are no longer believed to be associated with MHS.
- Increased muscle mass, especially in bodybuilders, appears to be an independent predictor of increased susceptibility to, recurrence of, and death from MH episodes. This finding is independent of the increased incidence in males noted above. Advanced age, muscularity, comorbidities, and disseminated intravascular coagulation (DIC) increase the risk of death.

GENETICS: Susceptibility to MH is due to at least six known genetic variations of MH, all of which are inherited in an autosomal dominant pattern. The most common is a mutation of the ryanodine receptor *RYR1,* causing MHS1. A *CACNA1S* mutation causes another form, *MHS5*. Other types are much less common, and in some cases (a *CACNA2D* mutation and *RYR1*) may interact (*MHS3*). Of note, patients with genetic susceptibility to MH may have an uneventful anesthesia while receiving known triggering agents; previous exposure does not exclude the possibility of a future MH crisis.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Within minutes to hours after a triggering agent is administered, the patient may develop muscle rigidity, with resulting tachypnea and tachycardia. In the operating room, MH is often difficult to recognize, and rigidity may be attributed to inadequate sedation or absent due to general anesthesia and muscle paralysis. Vital sign perturbations may be missed due to ongoing surgery.
- Masseter muscle rigidity is rare now that succinylcholine is used rarely for muscle relaxation and is not related to MHS.
- Manifestations of increased skeletal muscle metabolism include increased CO_2 production, leading to elevated mixed venous and arterial pCO_2, and an elevated $ETCO_2$; tachycardia is common.
- Hyperthermia or a rapidly increasing temperature from an anesthesia-induced hypothermic state, also a result of hypermetabolism, is present in more than 50% of MH events.
  1. Hyperthermia is not always present early in MH crisis, eliminating increasing core body temperature as a definitive inclusion factor in diagnosing MH at an early stage.
  2. Higher core body temperature correlates with increased morbidity.
- Muscle injury with an elevated creatine kinase (CK) may lead to rhabdomyolysis, observed myoglobinuria (if a urinary catheter is present), and subsequent acute renal failure. DIC may develop.
- The skin may be erythematous initially, progressing to a mottled, cyanotic appearance.
- Box 1 summarizes the findings consistent with MH.

ETIOLOGY: Approximately 50% of cases of MH susceptibility (MHS) are inherited (primarily MH1 and MH5); the remainder are presumed to be the result of a new mutations. The majority of the mutations, either inherited or de novo, are on chromosome 19 (19q13.2, with at least 35 variants), but other mutations may be found at 1q32.1 (*CACNA1S* with at least five variants), 17q11.2-q24, 7q21.2, 3q13.1, or 5p. The result is the abnormality of skeletal muscle calcium homeostasis and susceptibility to MH, with significant clinical variability due to incomplete penetrance and variable expressivity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Exertional heatstroke
- MH symptomology following excessive heat exposure to a MHS patient who did not receive a triggering agent
- Neuroleptic malignant syndrome
- Fever
- Thyrotoxicosis
- Pheochromocytoma
- Central nervous system infection or space-occupying lesion
- MDMA (Ecstasy), cocaine, alcohol withdrawal, or amphetamine use
- Serotonin syndrome
- Adverse reaction to monoamine oxidase inhibitors or anticholinergic drug
- Strychnine poisoning
- Sepsis

BOX 1 Positive Findings Consistent with Malignant Hyperthermia (MH)

History of recent exposure to trigger agent, including volatile anesthetic agents or succinylcholine
Family or personal history of MH susceptibility
Total body rigidity
Inappropriately elevated (38.8° C; 101.8° F) or rapidly increasing temperature (>1.5° C over 5 min)
Inappropriate tachypnea
Profuse sweating
Mottled, cyanotic skin
Dark urine, urine dipstick testing shows a positive result from blood without red cells in the sediment and no hemolysis
Unexplained, excessive bleeding
Unexplained ventricular tachycardia or fibrillation
Inappropriate hypercarbia (venous $Paco_2$ >65 mm Hg, arterial $Paco_2$ >55 mm Hg) if the patient is receiving positive-pressure ventilation or is spontaneously breathing with greater than normal minute ventilation
Arterial base excess more negative than –8 mEq/L
Arterial pH <7.25
Potassium concentration >6 mEq/L
Creatine kinase >10,000 IU/L

From Fuhrman BP et al: *Pediatric critical care*, ed 4, Philadelphia, 2011, Saunders.

- Drug withdrawal
- Rhabdomyolysis
- Transfusion reactions

WORKUP

- MH can often be distinguished from other causes of hyperthermia based on a history of exposure to a triggering agent.
- A rapid rise in $ETCO_2$ with no change in minute ventilation, especially in the setting of tachycardia, should prompt consideration of MH until proven otherwise.

LABORATORY TESTS

Considerations for laboratory testing fall into three scenarios:

- In the acute setting, electrolytes, arterial blood gas, and urine myoglobin to help confirm the diagnosis.
- Once the diagnosis is presumptive, it is important to monitor serial lab data including
  1. Blood gases
  2. Electrolytes, especially potassium and creatinine
  3. Creatine kinase
  4. Urine myoglobin
  5. Coagulation studies to evaluate for DIC
- If hyperthermia is less acute or the presentation atypical, thyroid function studies, CBC, toxicology screen, and urine vanillylmandelic acid (VMA) may be useful. Treatment should not be delayed while these labs are pending.

IMAGING STUDIES

A CT scan of the head may be obtained to evaluate for space-occupying lesion if clinically indicated. Imaging should never delay prompt treatment of strongly suspected MH.

SUSCEPTIBILITY TESTING:

- Testing for MH susceptibility involves genetic evaluation or the *in vitro* muscle contracture test.
  1. The *in vitro* muscle contracture test involves placing a muscle biopsy specimen in a bath of caffeine or halothane. Significant muscle contraction is 97% to 99% sensitive for MH susceptibility, with a specificity of 78% to 94% and a cost of $6 to $10,000. It is performed in only a few sites in the U.S.
  2. Genetic testing, while noninvasive, has a sensitivity of <50% and a cost of $1000 to $4000.
  3. Generally, a positive contracture test leads to genetic testing, unless there is a positive family history, in which case the patient may choose genetic testing directly.
- Testing for MHS can be performed preoperatively in patients deemed to be at risk or those with a personal or family history of anesthesia-induced complications suggestive of MH.
  1. Depending on the wishes of the patient and/or family following a thorough history and counseling, a decision to proceed with anesthesia and surgery without prior testing may be reasonable, with the avoidance of volatile agents or succinylcholine.
  2. In such a case, the patient should be counseled that forgoing testing may place them at risk if an intubation is required in an emergency setting, succinylcholine is used unknowingly, and the patient is truly MHS.
- After an acute event, the patient should undergo susceptibility testing to confirm the diagnosis and the need for testing other immediate family members at risk. If positive, the patient should be given a letter and wear a medical alert bracelet.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

- The patient should be cooled to 38° C. This can be accomplished with ice packs to the axillae and groin, a cooling blanket, a fan with cool mist, or chilled IV fluids. In extreme situations, partial extracorporeal bypass or iced peritoneal lavage have proven helpful.
- Frequent evaluation of core temperature, hemodynamics, and gas exchange are imperative.

ACUTE GENERAL Rx (SEE BOX 2)

- Notify the surgeon to stop surgery immediately. Discontinue all triggering agents and switch to nontriggering agents if surgery must be continued.
- Get dantrolene and your hospital's MH cart; call for help.
- Hyperventilate with 100% oxygen at flows of 10 L/min to flush volatile anesthetics and decrease $ETCO_2$. Insert charcoal filters, if available, into the inspiratory and expiratory limb of the breathing circuit to further absorb agent.
- Administer dantrolene as a rapid IV bolus at a dose of 2.5 mg/kg through a large bore catheter. Repeat every five minutes until an observable decrease is seen in muscle rigidity, tachycardia, or $ETCO_2$; a total dose greater than 10mg/kg may be required, especially in patients with greater muscle mass.
- Up to 25% of patients will have recrudescence of their symptoms, on average 13 hours after the initiation of MH. Dantrolene, 1mg/kg IV every 4 to 6 hours or by continuous infusion at 0.1 to 0.3 mg/kg/hr IV, is recommended for at least 24 to 48 hours. Additional boluses may be needed for breakthrough signs.
- Recently, one study suggested that in at least one MH model involving the RyR receptor, dantrolene treatment may be ineffective in the setting of insufficient levels of cytoplasmic Mg^{++}. MgATP hydrolysis, a process that normally increases Mg^{++} during contraction, by itself may be insufficient to raise the Mg^{++} concentration in the setting of low resting Mg^{++} levels, thereby preventing dantrolene from being effective.
- Aggressive hydration with forced diuresis and alkalization of the urine should be instituted for rhabdomyolysis. Observe closely for the development of compartment syndrome, renal failure, and DIC. Beta-blockers and lidocaine may be useful for dysrhythmias. Use of calcium channel blockers should be avoided, as the combination with dantrolene may produce profound hyperkalemia and significantly depress cardiac function.

CHRONIC Rx

- MH is an acute disease, resolving in 24 to 48 hours with appropriate treatment.
- The MHS patient should be aware that exercise in excessive heat and/or humidity could trigger an episode of MH without exposure to a pharmacologic triggering agent.
- The patient as well as immediate family members should be advised to undergo susceptibility testing.
- The patient should be given a letter by his/her anesthesiologist and wear a medical alert bracelet.

BOX 2 Management of an Acute Malignant Hyperthermia Episode in the Intensive Care Unit

1. Administer high-flow 100% oxygen via a nonrebreathing mask and consider endotracheal intubation.
2. For ventilated patients, administer an FiO_2 of 1.0 and increase minute ventilation to control $PaCO_2$.
3. Administer dantrolene (2.5 mg/kg intravenously) over 10 min, and repeat until acidosis and muscle rigidity have resolved. Repeat dantrolene (1 mg/kg) every 6 hr.
4. Initiate cooling with ice packs in the axillae and groin; decrease room temperature; use hypothermia blankets, iced intravenous saline solution (10 ml/kg over 10 min, repeated as needed), and lavage body cavities with cold saline solution if temperature is greater than 39° C. Stop cooling when core temperature falls to 38° C.
5. Correct metabolic acidosis with sodium bicarbonate (1 to 2 mEq/kg initially), and give subsequent doses based on base excess and body weight.
6. Administer calcium chloride (10 mg/kg) or calcium gluconate (100 to 200 mg/kg) for cardiotoxicity associated with hyperkalemia.
7. Give regular insulin (0.1 U/kg) and glucose (0.3 to 0.5 g/kg) to correct hyperkalemia.
8. Administer lidocaine (1 mg/kg) to treat ventricular arrhythmias. Consider amiodarone (5 mg/kg IV) for refractory, stable ventricular tachycardia. Do not delay defibrillation or cardiopulmonary resuscitation if indicated by cardiovascular instability.
9. Maintain urine output of 2 ml/kg/hr with aggressive cold fluid administration, furosemide (0.5 to1 mg/kg), and additional mannitol (0.25 to 0.3 g/kg) if needed.
10. Consider quantitative end-tidal CO_2 monitoring.
11. Monitor core temperature (pulmonary artery, esophageal temperature probe, rectal probe).
12. Place arterial catheter for invasive blood pressure monitoring and frequent blood sampling. Consider central venous catheter and/or pulmonary artery catheter if indicated by cardiovascular instability.
13. Repeat venous blood gas and electrolytes until these normalize. Repeat CK at least every 6 hr while the patient is in ICU and then daily until CK returns to normal. Assess glucose, clotting function, and hepatic and renal functions, and treat symptomatically. Repeat lactic acid measurement after each dantrolene administration.
14. Consider hemodialysis if indicated.
15. Consider intensive care monitoring for at least 24 hr after MH episode or after recrudescence of MH.
16. Refer the patient for muscle caffeine-halothane contracture testing and consider genetic testing. Pursue a pathologic diagnosis for other occult myopathies.

CK, Creatine kinase; *ICU,* intensive care unit; *MH,* malignant hyperthermia.
From Fuhrman BP et al: *Pediatric critical care,* ed 4, Philadelphia, 2011, Saunders.

BOX 3 Anesthetics Associated with the Development of Malignant Hyperthermia and Neuroleptic Malignant Syndrome

Malignant Hyperthermia
Volatile Anesthetics
Desflurane, isoflurane, sevoflurane

Muscle Relaxants
Succinylcholine

Neuroleptic Malignant Syndrome
Phenothiazines
Fluphenazine, chlorpromazine, levomepromazine, thioridazine, trimeprazine, trifluoperazine, prochlorperazine

Butyrophenones
Haloperidol, bromperidol, droperidol
Dibenzoxazepine
Loxapine

Dopamine-Depleting Drugs
Alpha-methyltyrosine, tetrabenazine

Dopaminergic Agent Withdrawal
Levodopa-carbidopa, amantadine

Modified from Parrillo JE, Dellinger RP: *Critical care medicine: Principles of diagnosis and management in the adult*, ed 4, Philadelphia, 2014, Saunders.

COMPLEMENTARY & ALTERNATIVE MEDICINE

None

DISPOSITION

After MH crisis, patients should be admitted to the intensive care unit for at least 24 hrs where close monitoring and supportive care can be maximized.

REFERRAL

Anesthesiology, cardiology, nephrology, and hematology consultation as appropriate. After the acute event, a genetics consult may be warranted to facilitate testing

PEARLS & CONSIDERATIONS

COMMENTS

- MH is a life-threatening condition that requires prompt recognition to minimize illness, end-organ damage, and/or death.
- Family or personal history of problems with general anesthesia in the past are clues to susceptibility and should prompt careful preoperative evaluation.
- Prophylactic dantrolene is no longer recommended for known MHS patients undergoing general anesthesia with nontriggering agents.
- Box 3 summarizes anesthetics associated with the development of malignant hyperthermia and neuroleptic malignant syndrome.

PATIENT & FAMILY EDUCATION

- The patient and his/her family should be made aware of the diagnosis so that they can provide information to the anesthesiologist and other intraoperative caregivers when undergoing any type of surgery or procedure under sedation.
- The patient should be given a letter that can be shown to future care givers.
- A medical alert bracelet should be recommended.

Mallory-Weiss Tear PTG ALG

BASIC INFORMATION

DEFINITION

A Mallory-Weiss tear (MWT) is a longitudinal mucosal laceration in the region of the gastroesophageal junction and gastric cardia typically occurring after repeated episodes of severe vomiting or retching.

SYNONYMS

Mallory-Weiss syndrome
MWT

ICD-10CM CODE
K22.6 Mallory-Weiss syndrome

EPIDEMIOLOGY & DEMOGRAPHICS

- Accounts for 5% to 15% of cases of upper gastrointestinal (GI) bleeding
- Reported from early childhood to old age; the majority of patients are age 40 to 60 yr
- More common in males
- Alcohol use is present in 30% to 60%

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Vomiting, retching, or vigorous coughing will often, but not always, precede hematemesis.
- Patients may be clinically stable or present with tachycardia, hypotension, melena, hematochezia, epigastric pain, back pain, syncope, or hemorrhagic shock.
- Bleeding may be self-limited or severe. Rebleeding is more common in patients with advanced alcoholic liver disease.
- Tears may be seen in association with other upper GI tract lesions, including hiatal hernia (present in as many as 90% of patients), ulcers, and esophageal varices, particularly in alcoholics.

ETIOLOGY

- An acute increase in intragastric and intraabdominal pressure is transmitted to the gastroesophageal junction and esophagus, resulting in mucosal laceration.
- Vomiting may be associated with alcohol use, cannabinoid use, ketoacidosis, ulcer disease, uremia, pancreatitis, chemotherapy, cholecystitis, pregnancy (in particular associated with hyperemesis gravidarum), bulimia, myocardial infarction, or the postoperative period.
- Infrequently reported causes include chest wall trauma (including CPR), hiccups, coughing, seizures, lifting/straining, blunt abdominal trauma, acute severe asthma, labor and delivery, and even primal scream therapy.
- Tears may be iatrogenic, related to routine endoscopy (especially in struggling, retching, or older patients, or in association with hiatal hernias or distal gastrectomy), enteroscopy with or without overtubes, esophageal dilation, lower esophageal pneumatic disruption therapy for achalasia, endoscopic submucosal dissection, transesophageal echocardiography, or in association with polyethylene glycol electrolyte colonic lavage preparation.
- Tears are frequently found on the right lateral wall of the esophagus.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Esophageal or gastric varices
- Esophagitis or esophageal ulcers (peptic or pill-induced)
- Gastric erosions
- Gastric or duodenal ulcer
- Dieulafoy lesion
- Arteriovenous malformations
- Neoplasms (usually gastric)
- Boerhaave syndrome

WORKUP

Endoscopy is the diagnostic method of choice.

LABORATORY TESTS

- Complete blood count, prothrombin time, partial thromboplastin time
- Electrolytes, blood urea nitrogen, creatinine, liver function tests, pregnancy test, tests to evaluate for predisposing conditions

IMAGING STUDIES

- Upper GI series is usually not sensitive.
- Patients with concurrent chest pain, dyspnea, shock, or physical examination findings of crepitus or pleural effusion should have a chest radiograph or CT to exclude Boerhaave syndrome.

TREATMENT

NONPHARMACOLOGIC THERAPY

- Supportive care
- Avoidance of aspirin, nonsteroidal antiinflammatory drugs, and anticoagulants

ACUTE GENERAL Rx

- Patients with active bleeding or hemodynamic instability require large-bore IVs, fluid resuscitation, transfusion of blood products (red blood cells, fresh frozen plasma, platelets) and holding or reversal of anticoagulation as appropriate.
- Nasogastric decompression and antiemetics may be considered.
- Endoscopic therapy for patients with active or ongoing hemorrhage (Fig. E1). Therapeutic modalities include electrocoagulation, argon plasma photocoagulation, heater probe coagulation, injection (e.g., 1:10,000 epinephrine, polidocanol), sclerotherapy (for bleeding associated with esophageal varices), band ligation, endoscopic hemoclips (Fig. E2), over-the-scope clips, and hemostatic sprays (therapies may be used alone or in combination) (Fig. E3). Hemoclips combined with a nylon snare ("tulip-bundle" technique) have been successfully used for refractory bleeding.
- Arterial embolization in patients with active bleeding who are poor surgical candidates.
- Laparotomy, with gastrotomy and oversewing of the tear, is required in a small percentage of patients with uncontrolled bleeding.

CHRONIC Rx

- Healing will usually occur without specific therapy.
- H_2 blockers or proton pump inhibitors may be given to help facilitate healing but should not be used long term unless appropriate indications are present.

DISPOSITION

- Prognosis is good, with spontaneous cessation of bleeding in upward of 90% of patients. Endoscopic features can guide treatment. Blatchford score <6 suggests no need for transfusion or endoscopic intervention.
  1. Blatchford score is calculated by certain indices (sex, blood urea nitrogen, hemoglobin, systolic blood pressure, pulse, and the presence of melena, syncope, hepatic disease, or cardiac failure) and is used to determine which patients need clinical intervention for acute upper gastrointestinal bleeding.
- Delayed rebleeding is described in patients with high-risk stigmata (shock at initial presentation, spurting, or oozing at initial endoscopy).
- Death has been reported in 3% to 12%, often in association with severe bleeding and underlying comorbid conditions such as advanced age, coagulopathy, elevated transaminases, thrombocytopenia, alcohol use, presentation with a very low hemoglobin level or melena, and multi-system organ failure. Over the past decade, associated mortality appears to be significantly declining.

REFERRAL

- Gastrointestinal referral for endoscopy
- Surgical referral for bleeding unresponsive to endoscopic treatment or in the setting of coexistent perforation

PEARLS & CONSIDERATIONS

Conditions predisposing to retching or vomiting should be identified and treated at presentation.

BASIC INFORMATION

DEFINITION

Marfan syndrome (MFS) is an inherited disorder of connective tissue involving the skeleton, cardiovascular system, eyes, lungs, and central nervous system.

SYNONYM

MFS

ICD-10CM CODES

Q87.40	Marfan syndrome, unspecified
Q87.410	Marfan syndrome with aortic dilation
Q87.418	Marfan syndrome with other cardiovascular manifestations
Q87.42	Marfan syndrome with ocular manifestations
Q87.43	Marfan syndrome with skeletal manifestation

EPIDEMIOLOGY & DEMOGRAPHICS

PREVALENCE:

- One case per 10,000 persons.
- Both sexes are affected equally by this autosomal-dominant syndrome.
- Approximately 30% of cases are a new mutation.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Diagnostic criteria for MFS (Table E1):

- Skeleton: Joint hypermobility (Fig. E1), tall stature (Fig. E2A), pectus excavatum, reduced thoracic kyphosis, scoliosis, arachnodactyly (Fig. E2B), dolichostenomelia, pectus carinatum, and erosion of the lumbosacral vertebrae from dural ectasia
- Eye: Myopia, retinal detachment, elongated globe, ectopia lentis
- Cardiovascular: Mitral valve prolapse, endocarditis, arrhythmia, dilated mitral annulus, mitral regurgitation, tricuspid valve prolapse, aortic regurgitation, aortic dissection, dilation of the aortic root
- Pulmonary: Apical blebs, spontaneous pneumothorax
- Skin and integument: Inguinal hernias, incisional hernias, striae atrophicae
- Central nervous system: Attention deficit disorder, hyperactivity, verbal-performance discrepancy, dural ectasia, anterior pelvic meningocele

If the family history is positive for a close relative clearly affected by MFS, manifestations should be present in the skeleton and one of the other organ systems and the diagnosis confirmed by linkage analysis or mutation detection.

If the family history is negative or unknown, the patient should have manifestations in the skeleton, the cardiovascular system, and one other system and at least one of the manifestations indicated by an asterisk in the previous lists.

Manifestations are listed within each organ system in increasing specificity for MFS; although none is completely specific, those indicated by an asterisk are the most specific.

ETIOLOGY

Mutations in the gene that encodes fibrillin-1 (FBN_1), the major constituent of microfibrils, which form the frame for elastic fibers. All the manifestations of MFS can be explained by the defective microfibrils.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Each of the clinical manifestations of the syndrome may have other causes; however, if the diagnostic criteria are met, the diagnosis is made. Table E2 summarizes the differential diagnosis of Marfan syndrome.

WORKUP

- MFS diagnosis is made clinically, with genetic consultation if necessary
- Echocardiography to establish:
  1. Mitral valve prolapse
  2. Mitral regurgitation
  3. Tricuspid valve prolapse
  4. Aortic regurgitation
  5. Dilation of the aortic root
- Echocardiography should be repeated 6 mo after initial diagnosis to evaluate for rate of aortic diameter enlargement

TABLE E1 Diagnostic Criteria for Marfan Syndrome

In the absence of a family history of MFS, a diagnosis can be reached in one of four scenarios:
1. Aortic diameter at Sinuses of Valsalva Z-score ≥2 AND Ectopia Lentis = MFS*
2. Aortic diameter at Sinuses of Valsalva Z-score ≥2 AND *FBN1* mutation = MFS
3. Aortic diameter at Sinuses of Valsalva Z-score ≥2 AND Systemic Score ≥7 = MFS*
4. Ectopia Lentis AND *FBN1* mutation known to associate with aortic aneurysm = MFS

In the absence of a family history of MFS, alternative diagnoses include:
1. Ectopia lentis, 6 Systemic Score, AND *FBN1* mutation not known to associate with aortic aneurysm or no *FBN1* mutation = Ectopia lentis syndrome
2. Aortic diameter at sinuses of Valsalva Z-score >2 AND systemic score 2:5 (with at least one skeletal feature) without ectopia lentis = MASS phenotype
3. Mitral valve prolapse AND aortic diameter at sinuses of Valsalva Z-score <2 AND Systemic Score <5 without ectopia lentis = mitral valve prolapse syndrome

In the presence of a family history of MFS, a diagnosis can be reached in one of three scenarios:
1. Ectopia lentis AND family history of MFS = MFS
2. Systemic Score ≥7 AND family history of MFS = MFS*
3. Aortic diameter at sinuses of Valsalva Z-score ≥2 if older than 20 yr or ≥3 if younger than 20 yr AND family history of MFS = MFS*

Scoring of Systemic Features (in points)†

Wrist AND thumb sign = 3 (wrist OR thumb sign = 1)

Pectus carinatum deformity = 2 (pectus excavatum or chest asymmetry = 1)

Hindfoot deformity = 2 (plain pes planus = 1)

Pneumothorax = 2

Dural ectasia = 2

Protrusio acetabuli = 2

Reduced US/LS AND increased arm/height AND no severe scoliosis = 1

Scoliosis or thoracolumbar kyphosis = 1

Reduced elbow extension = 1

Facial features (3/5) = 1 (dolichocephaly, enophthalmos, downslanting palpebral fissures, malar hypoplasia, retrognathia)

Skin striae = 1

Myopia >3 diopters = 1

Mitral valve prolapse (all types) = 1

Criteria for causal *FBN1* mutation

Mutation previously shown to segregate in a Marfan family

Any one of the following *de novo* mutations (with proven paternity and absence of disease in parents):

Nonsense mutation

In-frame and out-of-frame deletion/insertion

Splice site mutations affecting canonical splice sequence or shown to alter splicing on mRNA/cDNA level

Missense mutation affecting/creating cysteine residues

Missense mutation affecting conserved residues of the EGF consensus sequence [(D/N)X(D/N)(E/Q)Xm(D/N)Xn(Y/F), with m and n representing variable number of residues; D, aspartic acid; N, asparagine; E, glutamic acid; Q, glutamine; Y, tyrosine; F, phenylalanine]

Other missense mutations: Segregation in family, if possible, + absence in 400 ethnically matched control chromosomes; if no family history, absence in 400 ethnically matched control chromosomes

Linkage of haplotype for n≥6 meioses to the *FBN1* locus

*Without discriminating features of Shprintzen-Goldberg syndrome, Loeys-Dietz syndrome, or Ehlers-Danlos syndrome *and* after TGFBR1/2, collagen biochemistry, COL3A1 testing if indicated. Other conditions/genes will emerge with time.
†Maximum total: 20 points; score ≥7 indicates systemic involvement.
MASS, Mitral valve, myopia, aorta, skin and skeletal features; *MFS,* Marfan syndrome; *US/LS,* upper segment/lower segment ratio.
From Loeys BL et al: The revised Ghent nosology for the Marfan syndrome, *J Med Genet* 47(7):476–485, 2009.

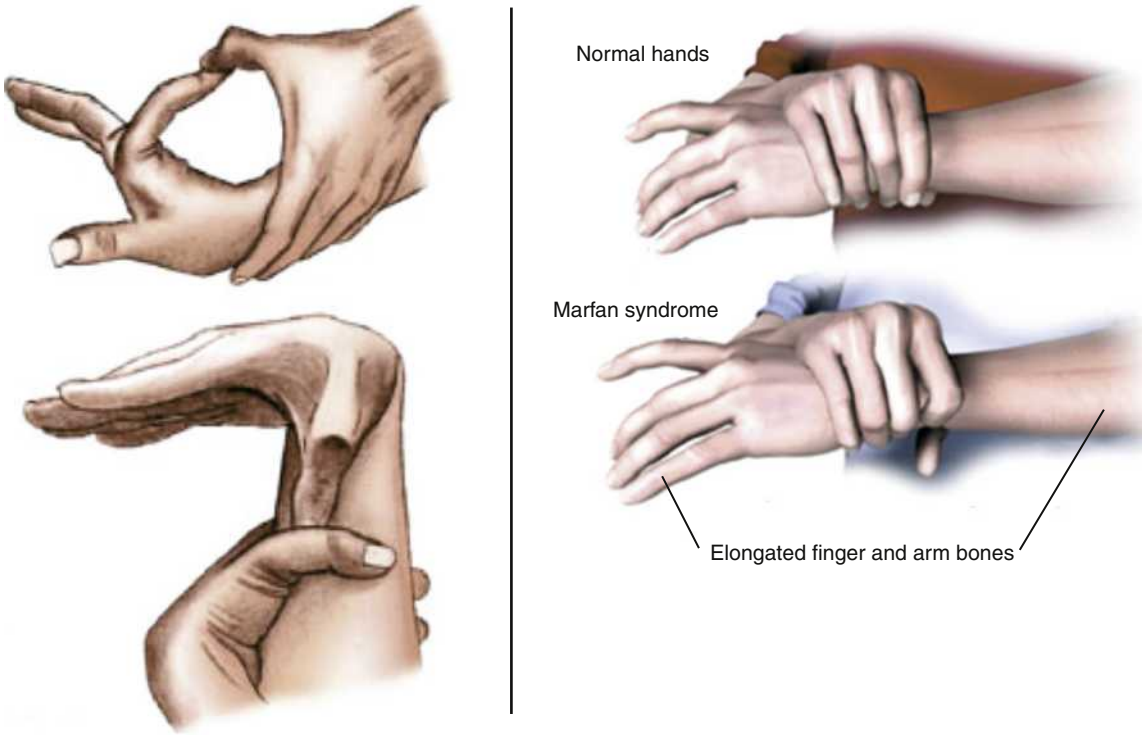

FIG. E1 Marfan syndrome. The Steinberg test (thumb) and the Walker-Murdoch test (wrist) show arachnodactyly. (From Firestein GS et al: *Kelley's textbook of rheumatology,* ed 9, Philadelphia, 2013, WB Saunders, Elsevier.)

- Chest radiograph
- Transesophageal echocardiography, chest CT scan, chest MRI, or aortography for suspected aortic dissection
- Chest radiograph for pulmonary apical bullae
- Ophthalmologic examination by ophthalmologist
- Testing for FBN_1 mutations is available

Rx TREATMENT

- Regular cardiac and aorta monitoring by physical examination and echocardiography. Surgical repair of the dilated aortic root/ascending aorta is generally performed when external diameter is ≥5 cm. Surgical repair may be performed earlier (at >4.0 cm diameter) in women contemplating pregnancy.
- Endocarditis prophylaxis.
- Restriction of contact sports, weight lifting, and overexertion.
- Beta-blockers are commonly prescribed to slow the rate of aortic root dilation. Patients with MFS and associated aneurysm should be receiving beta-blockers unless there is a contraindication to their use. Recent reports indicate that use of angiotensin receptor blockers also significantly slowed the rate of progressive aortic root dilation independent of hemodynamic effects. A recent trial among children and young adults with MFS who were randomly assigned to losartan or atenolol found no significant difference in the rate of aortic root dilation between the two treatment groups over a 3-yr period.[1]
- Genetic counseling.
- Monitor aorta during pregnancy because of the increased risk of dissection.

Marfan Syndrome (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

[1] Lacro RV, Sleeper LA et al: Atenolol versus losartan in children and young adults with Marfan's syndrome, *N Engl J Med* 371(21):2061-2071, 2014.

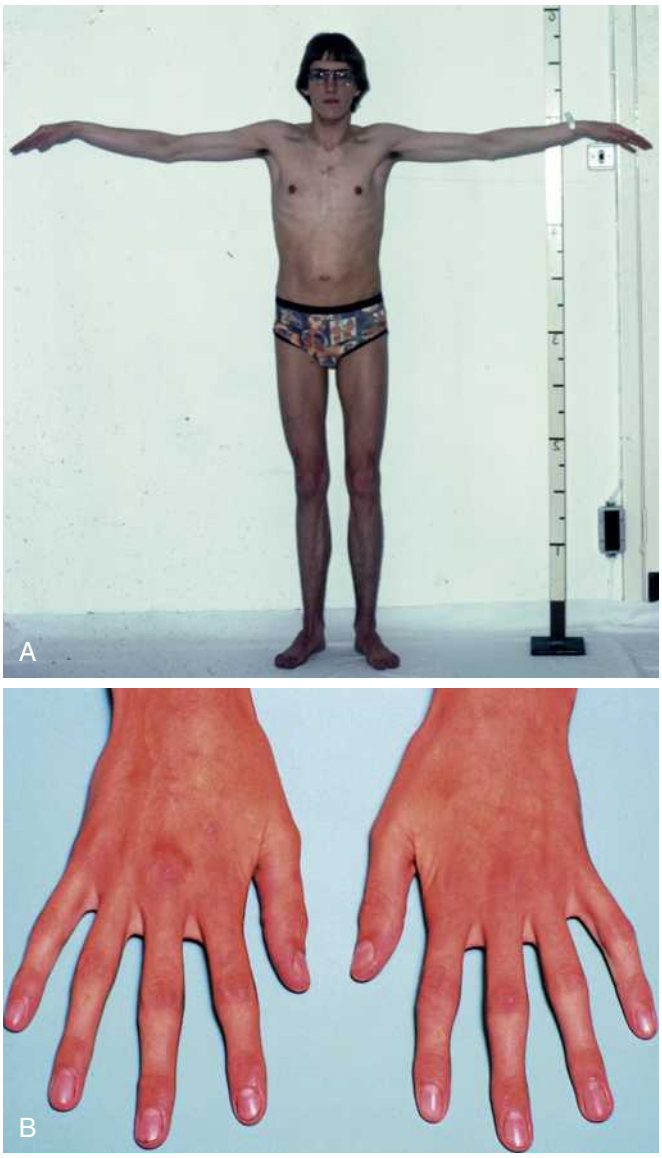

FIG. E2 **A**, Long limbs compared with the trunk. **B**, Arachnodactyly. (From Kanski JJ, Bowling B: *Clinical ophthalmology, a systematic approach,* ed 7, Philadelphia, 2010, WB Saunders.)

TABLE E2 Diagnostic Criteria for Marfan Syndrome

In the absence of a family history of MFS, a diagnosis can be established in four distinct scenarios:

1. Aortic root Z score ≥2 AND ectopia Lentis*
2. Aortic root Z score ≥2 AND a bona fide *FBN1* mutation
3. Aortic root Z score ≥2 AND a systemic score ≥7*
4. Ectopia lentis AND a bona fide *FBN1* mutation known to cause aortic disease

In the presence of a family history of MFS, a diagnosis can be established in the presence of:

1. Ectopia lentis
2. A systemic score ≥7*
3. Aortic root Z score ≥2 if older than 20 yr or ≥3 if younger than 20 yr*

In the absence of a family history of MFS, alternative diagnoses include:

1. Ectopia lentis ± systemic score AND *FBN1* mutation not known to associate with aortic aneurysm or no *FBN1* mutation = Ectopia lentis syndrome
2. Aortic root Z score <2 AND a systemic score ≥5 (with at least 1 skeletal feature) without ectopia lentis = MASS phenotype
3. Mitral valve prolapse AND Aortic root Z score <2 AND a systemic score <5 without ectopia lentis = Mitral valve prolapse syndrome

*Denotes caveat that features suggestive of an alternative diagnosis must be excluded and appropriate alternative molecular testing should be performed.

MASS, Mitral valve, myopia, aorta, skin, and skeletal features; *MFS,* Marfan syndrome.

BASIC INFORMATION

DEFINITION

Mastitis is local painful inflammation of the breast that may or may not be accompanied by infection, flulike symptoms, and abscess formation.

ICD-10CM CODES

N61	Inflammatory disorders of breast
O91.12	Abscess of breast associated with the puerperium
O91.22	Nonpurulent mastitis associated with the puerperium

EPIDEMIOLOGY & DEMOGRAPHICS

- Mastitis is the most common cause of inflammatory breast disease, and most cases are related to lactation.
  1. Nonpuerperal cases of mastitis can affect either the periareolar (periductal) region or peripheral breast tissue.
  2. Periductal mastitis is most common in younger, reproductive-age women. The majority of those affected are active smokers.
- In lactating mothers, mastitis typically occurs in the first 3 mo of the postpartum period (74% to 95% of cases).
- When severe, mastitis can lead to a breast abscess (5% to 11%) or septicemia.
- Delayed diagnosis and treatment of lactational mastitis can lead to discontinuation of breastfeeding, breast tissue damage, or recurrence.
- In younger, nonlactating women, infection often presents as periductal mastitis (PM) and is caused by inflamed milk ducts near the nipple.
- Granulomatous mastitis (GM) is a rarer form of benign inflammation of the breast and also most commonly occurs in reproductive-age women. It generally affects the breast peripherally.
- Mastitis also can occur in infancy when there is breast hypertrophy from maternal hormone.

PREVALENCE: Lactational mastitis occurs in up to 33% of mothers.

PREDOMINANT SEX: Females

RISK FACTORS:

- Previous mastitis
- Milk stasis and missed feedings
- Cracked, fissured, or sore nipples
- Primiparity and infant attachment difficulties
- Cleft lip or palate or short frenulum in infant
- Use of manual breast pump
- Diabetes
- Breast implants
- Nipple piercings
- Rapid weaning
- Smoking (periductal mastitis)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Warmth, redness, tenderness in breast
- Unilateral or bilateral
- Malaise, myalgias, fevers, chills
- Decreased milk output
- Breast is hard and swollen in a wedge-shaped area
- In PM, breast mass near nipple with retraction or discharge
- In GM, enlarged axillary lymph nodes or sinus tract formation

ETIOLOGY

- In lactational mastitis, infection occurs as a result of milk stasis and irritation of the milk ducts due to local immune response to milk proteins.
  1. Bacterial infection of subcutaneous tissue due to breaks in skin.
- Most commonly, *S. aureus;* less common, *S. epidermidis,* group A beta-hemolytic streptococci, *S. pneumoniae, E. coli, Candida albicans, M. tuberculosis.* GM results from inflammation with epithelioid histiocytes and multinucleated giant cells and can be caused by etiologies like tuberculosis, sarcoidosis, foreign body reaction, parasitic and mycotic infections, or idiopathic.
- Periductal mastitis occurs following inflammation around nondilated subareolar ducts and often can progress to abscess formation. Peripheral abscesses can result from trauma, usually in the setting of comorbid conditions impairing immunity such as diabetes or use of immunosuppressive medications.
- Neonatal mastitis caused by *S. aureus* or gram-negative enteric bacteria.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Engorgement, plugged duct (see Table 1)
- Breast abscess
- Inflammatory or other breast cancer (3% of women diagnosed with breast cancer are lactating)
- Mastitis as a symptom of hyperprolactinemia or galactorrhea
- GM can be manifestation of systemic disease (sarcoidosis, Wegener granulomatosis, giant cell arteritis (GCA), polyarteritis nodosa, tuberculosis (TB), syphilis)

WORKUP

- History and clinical exam with thorough breast exam and assessment of axillary nodes and nipple discharge are sufficient for diagnosis.
- Recurrent mastitis should include workup for underlying breast disease.

LABORATORY TESTS

- Simple lactational mastitis requires no milk culture or laboratory studies.
- Obtain midstream sample of milk for culture and sensitivities in refractory mastitis or in methicillin-resistant *Staphylococcus aureus*-suspected cases.
- CBC and blood cultures in toxic patients.
- In abscess formation, culture of drainage or aspirate fluid.
- Gram stain and culture indicated in infant mastitis.

IMAGING STUDIES

- Not necessary unless refractory mastitis or abscess suspected
- Consider ultrasound (US) (Fig. E1) to evaluate for abscess or mammogram when appropriate to exclude carcinoma
- In GM, mammogram and US-guided fine needle aspiration (FNA) are standard

TREATMENT

NONPHARMACOLOGIC THERAPY

- Mainstay of therapy is effective milk removal through continued breastfeeding or pumping.
- Consider referral to a certified lactation consultant to improve breastfeeding technique.
- Warm compresses, increased fluid intake, good nutrition, and rest.
- In abscess formation (10% of women who are treated for bacterial mastitis), surgical drainage or needle aspiration is necessary, followed by antibiotic therapy based on sensitivities of culture.

ACUTE GENERAL Rx

- NSAIDs and analgesics (e.g., acetaminophen, ibuprofen). There is insufficient evidence to support or refute the effectiveness of antibiotic therapy. Common regimens include:
- No history of MRSA:
  1. Dicloxacillin 250 mg 4×/day for 7 days
  2. Cephalexin 500 mg 4×/day for 10 to 14 days
  3. Inpatient: Nafcillin or oxacillin 2 g IV q4h
  4. Erythromycin may be used in patients allergic to penicillin
- Suspected MRSA or high-risk penicillin allergy:
  1. Trimethoprim/sulfamethoxazole 160 mg/800 mg 2×/day for 10 to 14 days; should not be used when breastfeeding healthy infants <2 mo or compromised infants
  2. Clindamycin 300 mg 4×/day for 10 to 14 days
  3. Inpatient: Vancomycin 1 g IV q12h
- Oxytocin nasal spray if letdown reflex disturbed

TABLE 1 Comparison of Findings of Engorgement, Plugged Duct, and Mastitis

Characteristics	Engorgement	Plugged Duct	Mastitis
Onset	Gradual, immediately	Gradual, after feedings	Sudden, after 10 days postpartum
Site	Bilateral	Unilateral	Usually unilateral
Swelling and heat	Generalized	May shift/little or no heat	Localized red, hot, and swollen
Body temperature	<38.4° C; 101.1° F	<38.4° C; 101.1° F	>38.4° C; 101.1° F
Systemic symptoms	Feels well	Feels well	Flulike symptoms

From Lawrence RA, Lawrence RM: *Breastfeeding: a guide for the medical profession,* ed 5, St Louis, 1999, Mosby.

- Consider treatment for candidal infection if bilateral symptoms and infant with thrush
  1. Topical clotrimazole for mother and oral nystatin for infant, with careful washing of all pacifiers and nipples
  2. If resistant to topical treatment, can consider oral fluconazole; however, data in breastfeeding are limited
- Infant mastitis typically is treated in an inpatient setting with parenteral antibiotics based on results of Gram stain.
- Most PM cases are treated adequately with a combination of antibiotics, needle aspiration/incision, and drainage. In recurrent cases, surgical removal of diseased ducts may be needed.
- If antibiotic and NSAID treatment for GM fails, immunosuppressive drugs (steroids, methotrexate) can be used. Surgical management is not recommended due to associated slow wound healing.

CHRONIC Rx

- No evidence proving benefit of prophylactic antibiotics to prevent lactational mastitis
- In GM, systemic corticosteroids or wide surgical resection

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Complementary therapies not assessed in prospective studies: *Belladonna, Phytolacca, Chamomilla,* sulfur, *Bellis perennis.*
- Several strains of lactobacilli have shown promise as probiotic agents that might be useful in treating mastitis, including *L. fermentum* and *L. salivarius.* These results should be replicated before this approach is adopted widely.

REFERRAL

Refer to surgeon for severe PM or significant lactational abscess that does not resolve with conservative measures

PEARLS & CONSIDERATIONS

COMMENTS

- 25% of breastfeeding mothers with one episode of mastitis stop breastfeeding.
- Increasing incidence of MRSA mastitis.
- Lactational mastitis is a risk factor for vertical transmission of infections (i.e., HIV-1, cytomegalovirus, measles, hepatitis B and C).
- When reassessing refractory nonlactational mastitis, the most important consideration is the possibility of cancer.
- Nonlactational mastitis can be a manifestation of systemic disease.
- GM mimics breast cancer both clinically and radiologically (>50% of reported cases are initially mistaken for carcinoma). This includes fine needle aspiration, which is sometimes interpreted as malignant.

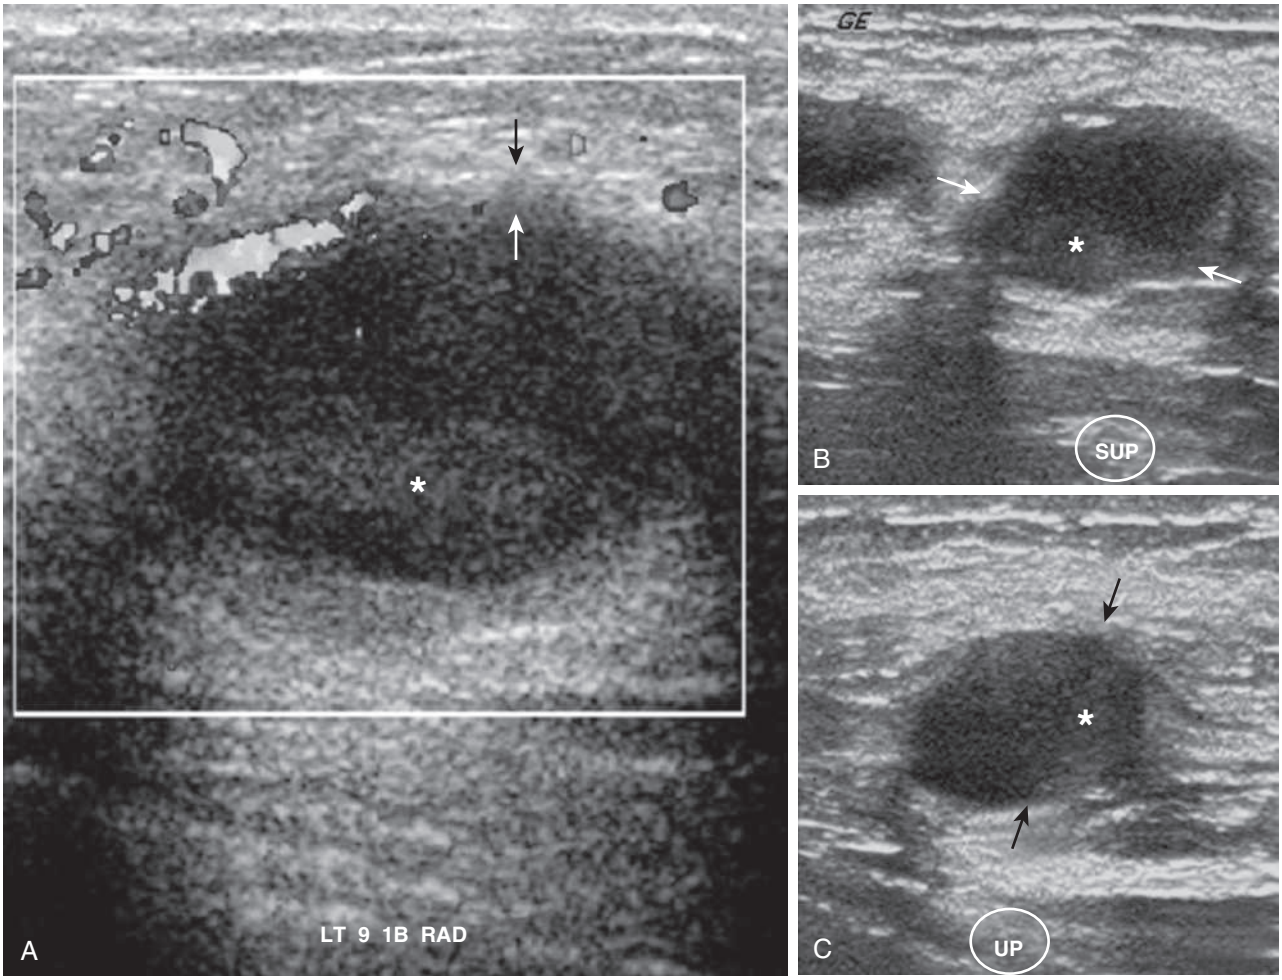

FIG. E1 Inflamed or infected cyst. A, Acutely inflamed or infected cysts demonstrate three findings: (1) Abnormal uniform isoechoic wall thickening *(between arrows),* (2) dependent debris *(asterisk)*, and (3) hyperemia of the thickened wall. **B,** Supine and **C,** upright images show the debris *(asterisk),* resembling sludge within a gallbladder, shifting to the dependent part of the cyst when the position of the patient is changed from supine to upright or lateral decubitus positions. Note the change in the position of the interface between the nondependent fluid and the dependent debris or pus *(between arrows).* (From Rumack CM et al: *Diagnostic ultrasound*, ed 4, Philadelphia, 2011, Mosby.)

BASIC INFORMATION

DEFINITION

Mastocytosis is a rare clonal hematopoietic disorder caused by the accumulation of abnormal mast cell population primarily in skin and bone marrow, and less commonly in liver and other tissues. Children usually have disease confined to the skin (urticaria pigmentosa) that resolves with adolescence. Adults typically have systemic disease of varying severity that is chronic. Indolent disease is typically defined by mast cell mediator related symptoms; advanced disease is associated with tissue injury from mast cell infiltrates and is less common.

SYNONYMS

Systemic mastocytosis
Urticaria pigmentosa (refers to skin disease only)
"Mastocytosis in the skin" (MIS, refers to skin disease only)

ICD-10CM CODES

Q82.2	Mastocytosis
D47.0	Indolent systemic
C96.2	Aggressive systemic
C96.2	Malignant
D47.0	Systemic, with an associated hematologic neoplasm (SM-AHM)

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (SYSTEMIC MASTOCYTOSIS [SM], EXCLUDING URTICARIA PIGMENTOSA [UP]):

- 0.4 per 1,000,000 persons per yr (U.S.).
- Male:female approximately equal.
- Age at diagnosis typically 50 to 70 yr.
- Approximately two thirds of cases are indolent (excluding UP and systemic mastocytosis-aggressive systemic mastocytosis [SM-ASM]).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Most symptoms are related to release of mast cell mediators, mainly histamine but also serotonin, heparin, several proteases (most important tryptase, which is a diagnostic marker), leukotrienes and numerous cytokines (e.g. IL-6).

SYMPTOMS

- Mast cell mediator symptoms:
  1. Cutaneous: Flushing, pruritus, urticaria, angioedema
  2. Extra-cutaneous: Lightheadedness, sometimes with syncope; palpitations; wheezing
- Gastrointestinal symptoms: Nausea/vomiting, diarrhea, constipation, bloating
- Musculoskeletal symptoms due to mastocytosis related osteopenia/osteoporosis or direct bone involvement with mast cells lesions: Bone pain, less commonly myalgia/arthralgia
- Severe anaphylactoid reactions, especially to Hymenoptera (bees, wasps, ants) venom

PHYSICAL EXAM

- Urticaria pigmentosa is the hallmark lesion of systemic mastocytosis. In adults, the lesions are small, brown/red (Fig. E1), generally flat (maculopapular). Pediatric lesions are commonly larger and may be more nodular or plaque like. In adults, skin lesions are usually seen in indolent mast cell disease, less common in advanced disease.
- *Darier sign*: Wheal and reddening of lesions with stroking, persisting minutes to hours.
- Hepatomegaly and/or splenomegaly are common in advanced disease.
- Lymphadenopathy, by exam or imaging, is detected in about 20% of cases.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Mastocytosis is a rare disorder with a wide spectrum of symptoms and presentations. It should be considered in the evaluation of severe urticarial reactions to Hymenoptera venom exposures (i.e., bee stings mainly), unexplained angioedema, episodic hypotension and unexplained nausea or diarrhea. It should also be considered in premature osteopenia/osteoporosis, especially in males.
- Elevated tryptase levels may be seen with many myeloid hematologic malignancies, transiently with allergic reactions and helminth infections.
- *Mast cell activation syndrome (MCAS)* is a disorder with mast cell mediator symptoms, possibly from hyperresponsive mast cells, but who lack pathologic findings of systemic mast cell disease.

WORKUP

- The World Health Organization (WHO) diagnostic criteria for various forms of mastocytosis are outlined in Tables E1, E2, and E3. Smoldering systemic mastocytosis (SSM) is the 2016 classification now defined by two or more "B" findings (Table E4).
- Serum tryptase: Approximately 20% of cases have serum tryptase less than the WHO cutoff of 20 ng/ml. Elevated levels have

FIG. E1 Urticaria pigmentosa lesions in a patient with cutaneous mastocytosis. (From Hoffman R [ed]: *Hematology: Basic principles and practice,* ed 6, Philadelphia, 2013, Elsevier/Churchill Livingstone.)

TABLE E1 World Health Organization Diagnostic Criteria for Systemic Mastocytosis[a]

Major Criterion

Multifocal, dense infiltrates of mast cells (>15 mast cells in aggregates) detected in sections of bone marrow and/or other extracutaneous organ(s)

Minor Criteria

a. In biopsy sections of bone marrow or other extracutaneous organs, >25% of the mast cells in the infiltrate are spindle-shaped or have atypical morphology; or of all mast cells in bone marrow aspirate smears, >25% are immature or atypical.
b. Detection of an activating point mutation at codon 816 in *KIT* in bone marrow, blood, or another extracutaneous organ.
c. Mast cells in bone marrow, blood, or other extracutaneous organs express CD2 and/or CD25 in addition to normal mast cell markers.
d. Serum total tryptase persistently exceeds 20 ng/ml (unless there is an associated clonal myeloid disorder, in which case this parameter is not valid).

[a]Requires at least one major + one minor criterion or three minor criteria.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE E2 2016 World Health Organization Variants of Mastocytosis

1. Cutaneous mastocytosis (CM)
   a. Maculopapular CM
   b. Diffuse CM
   c. Mastocytoma of skin
2. Indolent systemic mastocytosis (ISM)
   a. Isolated bone marrow mastocytosis
3. Smoldering systemic mastocytosis (SSM)
4. Systemic mastocytosis with an associated hematologic neoplasm (SM-AHN)*
   a. SM-MDS
   b. SM-MPN (e.g., PV, ET, MF, CML)
   c. SM-MDS/MPN (e.g., CMML, MDS/MPN-unclassified)
   d. SM-CEL
   e. SM-AML
   f. SM-lymphoid neoplasm (e.g., NHL, CLL, multiple myeloma)
5. Aggressive systemic mastocytosis (ASM)
6. Mast cell leukemia (MCL)
   a. Aleukemic MCL
7. Mast cell sarcoma (MCS)

*SM-AHN is a new term that may be used in lieu of the previous term, SM-AHNMD (systemic mastocytosis with an associated non-mast cell lineage disease).
AML, Acute myeloid leukemia; *CEL,* chronic eosinophilic leukemia; *CLL,* chronic lymphocytic leukemia; *CML,* chronic myeloid leukemia; *CMML,* chronic myelomonocytic leukemia; *ET,* essential thrombocythemia; *MDS,* myelodysplastic syndrome; *MF,* myelofibrosis; *MPN,* myeloproliferative neoplasm; *NHL,* non–Hodgkin lymphoma; *PV,* polycythemia vera.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

TABLE E3 2016 World Health Organization Diagnostic Criteria for Variants of (Systemic) Mastocytosis

1. **Indolent systemic mastocytosis (ISM):** Meets criteria for SM. No "B" or "C" findings. No evidence of associated clonal hematologic malignancy/disorder. In this variant, the mast cell burden is usually low; skin lesions are almost invariably present.
   - *Bone marrow mastocytosis:* As above, with bone marrow involvement, but no skin lesions.
2. **Smoldering systemic mastocytosis (SSM):** Meets criteria for SM. Two or more "B" findings and no "C" findings.
3. **Systemic mastocytosis with an associated hematologic neoplasm (SM-AHN)*:** Meets criteria for SM and an associated hematologic neoplasm (MDS, MPN, MDS/MPN, CEL, AML, lymphoma, or other hematologic neoplasm that meets the criteria for a distinct entity in the WHO classification).
4. **Aggressive systemic mastocytosis (ASM):** Meets criteria for SM. One or more "C" findings. No associated clonal hematologic neoplasm. No evidence of mast cell leukemia.
5. **Mast cell leukemia (MCL):** Meets criteria for SM. Bone marrow biopsy shows diffuse infiltration, usually in an interstitial pattern, by atypical, immature mast cells. Bone marrow aspirate smears show 20% or more mast cells. Cases in which <10% of circulating WBCs are mast cells are referred to as 'aleukemic mast cell leukemia.'
6. **Mast cell sarcoma (MCS):** Unifocal mast cell tumor. No evidence of SM. No skin lesions. Destructive growth pattern. High-grade cytology.

*SM-AHN is a new term that may be used in lieu of the previous term, SM-AHNMD (systemic mastocytosis with an associated non-mast cell lineage disease.)
AML, Acute myeloid leukemia; *CEL,* chronic eosinophilic leukemia; *MDS,* myelodysplastic syndrome; *MPN,* myeloproliferative neoplasm; *SM,* systemic mastocytosis; *WBC,* white blood cell; *WHO,* World Health Organization.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

high specificity (98%). May be elevated after urticarial reactions; should not be elevated at baseline.
- Skin biopsy (Fig. E2) for urticarial pigmentosa/mastocytosis in the skin (MIS).
- Bone marrow examination (Fig. E3) in adults with MIS or elevated tryptase. In adult patients with cutaneous MC lesions, the large majority ultimately will be found to have SM according to WHO diagnostic criteria. A bone marrow biopsy usually is recommended in these patients to establish a diagnosis of SM (Fig. E4).
- Flow cytometry/immune histochemistry for aberrant CD25 and/or CD2 expression, in addition to normal mast cell markers.
- Molecular studies (polymerase chain reaction, PCR) for *KIT* D816V mutation, preferably on tissue (marrow/skin); peripheral blood studies are less sensitive. If *KIT* D816V negative, consider evaluation for other *KIT* mutations.
- CBC and liver function studies; imaging of liver/spleen if appropriate.
- Bone density study for early osteoporosis in all patients; skeletal imaging if symptomatic (bone scan, plain x-rays).

Rx TREATMENT

Therapy is primarily directed to blockade of histamine release symptoms along with cytoreductive therapy for organ injury or refractory histamine release symptoms. Fig. E5 provides a treatment algorithm for indolent versus advanced stages of SM.
- Due to high incidence of anaphylaxis, epinephrine injectors are often recommended for mastocytosis patients.
- Triggers (e.g., alcohol, abrupt temperature changes) should be identified and avoided.
- Pruritus/flushing:
  1. H_1 blockade: Cetirizine, fexofenadine, others. Doses sometimes adjusted upwards with caution. Use with caution in glaucoma, BPH; may cause dry mouth

TABLE E4 "B" Findings: Indication of High Mast Cell Burden

1. Infiltration grade (mast cells) greater than 30% in bone marrow in histology and serum total tryptase levels greater than 200 ng/ml
2. Hypercellular marrow with loss of fat cells, discrete signs of dysmyelopoiesis without substantial cytopenias, and without WHO criteria for an MDS or MPN
3. Organomegaly: Palpable hepatomegaly, splenomegaly, or lymphadenopathy (on CT or ultrasound) greater than 2 cm without impaired organ function

CT, Computed tomography; *MDS,* myelodysplastic syndrome; *MPN,* myeloproliferative neoplasm; *WHO,* World Health Organization.
From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.

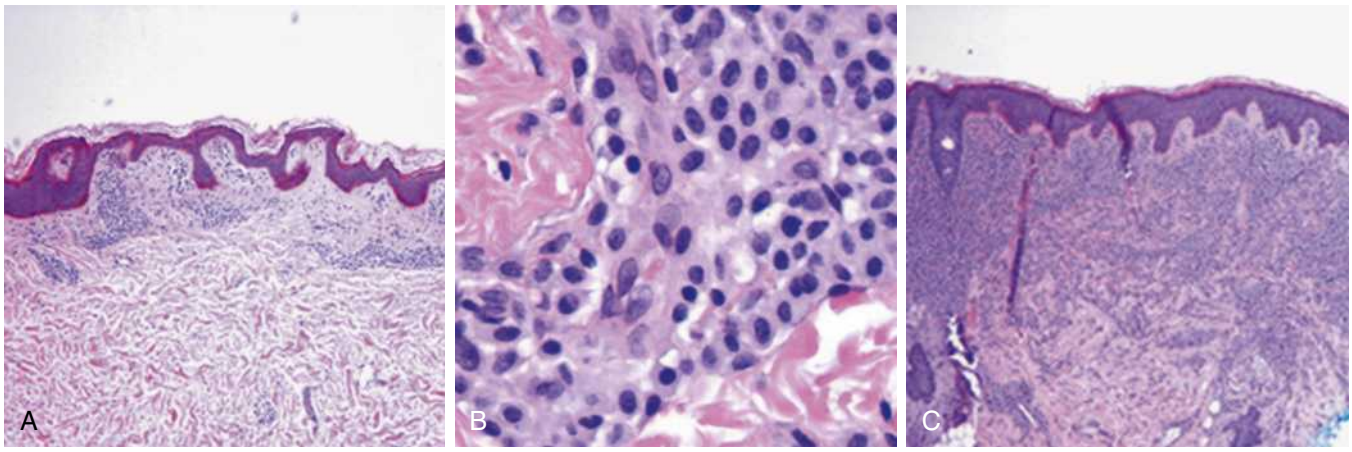

FIG. E2 Cutaneous mastocytosis. A skin biopsy of urticaria pigmentosa or maculopapular mastocytosis shows multiple focal aggregates of mast cells around blood vessels or skin appendages in the papillary dermis **(A).** The mast cells are plump with abundant cytoplasm and typically accumulate around vessels **(B,** *center***)**. In solitary mastocytoma of the skin or in diffuse cutaneous mastocytosis, the mast cell infiltrate is more extensive as it infiltrates the papillary and reticular dermis and even may extend into the subcutaneous tissues **(C).** The mast cells are bland and without cytologic atypia. In these disorders, there should be no evidence of systemic involvement. Evidence of systemic disease would indicate systemic mastocytosis. (From Hoffman R [ed]: *Hematology, basic principles and practice,* ed 6, Philadelphia, 2013, Elsevier/Churchill Livingstone.)

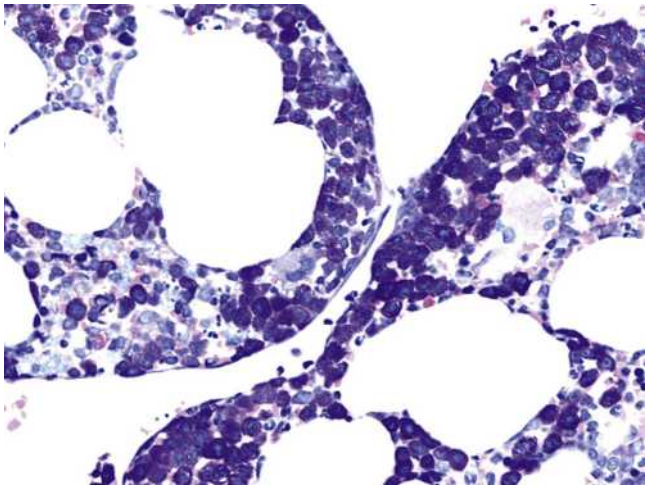

FIG. E3 Well-differentiated systemic mastocytosis. Core biopsy, Giemsa stain. Bone marrow shows aggregates of exclusively round mast cells with an abundance of metachromatic granules. This is the typical phenotypical appearance of a well-differentiated systemic mastocytosis. The disease otherwise was subtyped as indolent systemic mastocytosis with skin involvement but missing the *KIT* D816V mutation. There also was a lack of CD25 expression by the mast cells (not depicted). (From Hoffman R et al: *Hematology, basic principles and practice,* ed 7, Philadelphia, 2018, Elsevier.)

2. Leukotriene antagonist (second line): Montelukast or zafirlukast
3. Aspirin (third line): Low doses sometimes helpful
4. Psoralen and ultraviolet A light (PUVA) (third/fourth line)

- Abdominal pain/nausea/diarrhea/bloating:
  1. H_2 blockade: Ranitidine or famotidine
  2. Proton pump inhibitors (second line): Omeprazole, others
  3. Cromolyn sulfate (mast cell stabilizer, third line) before meals and HS. This agent is expensive; availability may vary
  4. Corticosteroids for short courses (fourth line)
- Recurrent hypotension:
  1. Epinephrine injector ("Epi-Pen")
  2. H_1/H_2 receptor blockade
  3. Specific therapy for defined allergies (e.g., bee stings)
- Osteoporosis:
  1. Bisphosphonates: Alendronate, others
  2. Optimize vitamin D/calcium replacement
- Cytoreductive therapy:
  1. Midostaurin, an oral multikinase inhibitor, is FDA-approved for treatment of ASM, SM-AHN, and mast cell leukemia (MCL). The response rate in ASM was 75%, and progression-free survival (PFS) was 28.7 mo; lower for SM-AHN and MCL
  2. Cladribine: A recent study found response rates of 72%, more durable in indolent disease (3.71 yr for indolent, 2.47 for advanced)
  3. Interferon alpha, given TIW, adjusted to response and tolerance
  4. Tyrosine kinase inhibitors such as imatinib mesylate have limited efficacy in *KIT* D816V mutated disease, but have use with other *KIT* mutations

DISPOSITION

- Indolent mastocytosis patients had survivals that roughly parallel age-matched controls in a study 159 patients seen between 1976 and 2007 at Mayo Clinic.
- Advanced mastocytosis patients had median survival of 41 mo. It is not known what impact changes in treatment standards in the current treatment era will have on survival.

AUTHOR: **Ritesh Rathore, MD**

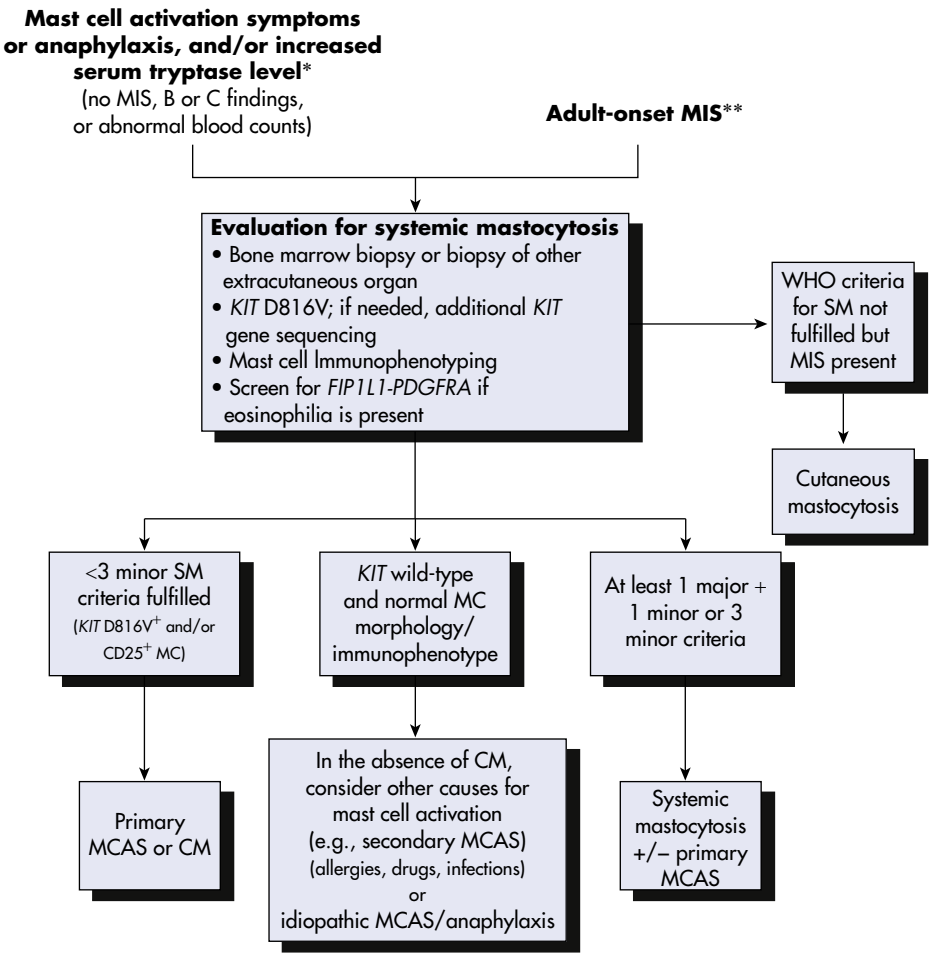

FIG. E4 Diagnostic decision pathways for patients with mast cell activation symptoms or adult-onset mastocytosis in the skin. For patients with mast cell activation symptoms or anaphylaxis (and/or increased serum tryptase level), or adult-onset MIS, screening to assess whether diagnostic criteria for SM are met should be the first diagnostic checkpoint. In patients not meeting the criteria for SM, evaluation for MCAS (primary vs. secondary vs. idiopathic) and idiopathic anaphylaxis is the next phase. Patients with MIS in whom no signs of SM can be found may be categorized as having cutaneous mastocytosis. *The serum tryptase level may be below the 20 ng/ml threshold, or only transiently elevated. **Although an evaluation for systemic mastocytosis generally is recommended in adults with MIS who have no blood count abnormalities or organ dysfunction and a normal or mildly increased serum tryptase level, the value of performing a bone marrow biopsy should be discussed with the patient. *CM,* Cutaneous mastocytosis; *MC,* mast cell; *MCAS,* mast cell activation syndrome; *MIS,* mastocytosis in the skin; *SM,* systemic mastocytosis; *PDGFRA,* platelet-derived growth factor receptor A; *WHO,* World Health Organization. BASIC INFORMATION

DEFINITION

- Pain in the breast
- Usually cyclic but may be noncyclic or extramammary

SYNONYM

Mastalgia

ICD-10CM CODE
N64.4 Mastodynia

EPIDEMIOLOGY & DEMOGRAPHICS

- Mastodynia affects up to 70% of women at some time in their reproductive lives.
- Severe cyclic mastodynia lasting more than 5 days/mo and of sufficient intensity to interfere with sexual, physical, social, and work-related activities is reported among 30% of premenopausal women.
- Underlying fear of breast cancer is the reason most of these women seek medical consultation.
- One tenth of women with mastodynia require pain-relieving therapy.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Usually the breasts are normal bilaterally.
- Generalized breast nodularity without discrete lumps.
- Chest wall tenderness: Extramammary breast pain, unilateral, aggravated by activity.
- Distinguishing mammary from extramammary pain can be difficult.
- With the patient lying on her side so that the breast tissue falls away from the chest wall, tenderness can then be reproduced by direct pressure over the offending site.
- Cyclic mastodynia presents in the luteal phase of the menstrual cycle one wk prior to onset of menses and resolves with menstruation.
- Women with cyclic mastodynia tend to have abdominal bloating, leg swelling, and other symptoms of premenstrual syndrome.
- Noncyclic mastodynia is unrelated to the menstrual cycle.
- Extramammary breast pain simulates noncyclic mastodynia.

ETIOLOGY

- Hormonal imbalance: Theories include increased estrogen, decreased progesterone, and increased prolactin
- Abnormal lipid metabolism, increased saturated fatty acids
- Premenstrual syndrome (20%)
- Fibrocystic breast disease, breast cysts
- Emotional abuse and anxiety
- Excessive caffeine intake has not been proven
- Breast cancer (10%)
- Mastitis
- Tietze syndrome (idiopathic costochondritis)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- See "Etiology."
- The majority of women with mastodynia have no underlying abnormality.
- Breast fullness and tenderness associated with hormonal changes fluctuate with the menstrual cycle.
- Similarly, breast nodularity, which may or may not be the result of fibrocystic breast disease, also fluctuates with the menstrual cycle.
- Discrete breast lumps need full evaluation to rule out malignancy.
- Tietze syndrome is usually unilateral and may be associated with chest wall swelling.

LABORATORY TESTS

Although hormonal imbalance and abnormal lipid metabolism have been implicated in the etiopathogenesis of mastodynia, there is no good evidence to support any consistent pattern of serum hormonal or lipid profile in women with mastodynia. These tests are therefore not recommended.

IMAGING STUDIES

- Cyclical, bilateral, nonfocal: Usually does not require imaging.
- Ultrasound is helpful in the assessment of cystic breast lesions.
- Unilateral, noncylical, focal: Imaging based on age
- Consideration of family history for breast disease is important.
- There are no radiologic features associated with mastodynia: Rather, radiologic investigations are performed to exclude the rare presence of a subclinical carcinoma.

TREATMENT

NONPHARMACOLOGIC THERAPY

- 78% to 85% of women with mastodynia can be reassured after full clinical evaluation. In fact, reassurance can be considered first-line therapy for mastodynia since many women who present are concerned about significant pathology, especially cancer.
- A firm, supportive brassiere designed for postpartum use is particularly helpful if mastodynia is associated with breast swelling.
- Follow a low-fat, high-carbohydrate diet.
- Reducing caffeine intake has not been proven effective but may help some women.

ACUTE GENERAL Rx

- There is limited evidence supporting the use of evening primrose oil, which contains gamma-linolenic acid, but this may be offered to patients as it is generally benign.
- Topical NSAID preparations (diclofenac, salicylate) may confer some benefit and can be prescribed for these women.
- Hormonal therapy is the mainstay of treatment and may include progesterone-only oral contraceptives or cyclic Provera.
- Danazol is the only drug approved by the FDA for the treatment of mastodynia. Danazol has some androgenic and peripheral antiestrogenic effects. Its efficacy is well established, with significant relief of mastodynia in 70% to 93% of cases.
  1. Widespread use of danazol is limited because of its adverse side effects. These include menstrual irregularities, depression, acne, hirsutism, and, in severe cases, voice deepening. Women should be advised to use effective nonhormonal contraception because of the drug's potential adverse effects on the fetus. It is imperative to rule out pregnancy prior to drug initiation.
  2. The side effects of danazol can be significantly reduced by using a low dose (100 mg daily) and confining treatment to 2 wk preceding menstruation. However, alternatives should be explored.
- Tamoxifen, a synthetic antiestrogen, has also been shown to be effective in the treatment of mastodynia. Although effective in relieving symptoms, its use is extremely limited because of side effects, although it has fewer than Danazol. When used, it should be at a low dosage of 10 mg/day and duration should be limited to 6 mo at a time. In the U.S. this agent is not approved for use in women with mastodynia.
- Bromocriptine is a dopamine-receptor agonist whose primary action is inhibition of prolactin release. It has been used extensively in the treatment of severe cyclic mastodynia and is effective. Again, side effects such as headache and lightheadedness have limited its use and it is less effective than Danazol.
- Lisuride maleate was recently found to be effective by one study.
- Other hormonal agents that have been reported to be effective in small studies cannot be recommended. Either they have unacceptable side effect profiles or their efficacy is not established. These agents include gestrinone, gonadotropin-releasing hormone analogues, progesterone, and hormone replacement therapy.
- Investigational treatments: Phytoestrogens, agnus cactus, chamomile.

CHRONIC Rx

- Longstanding cases of mastodynia can be managed with intermittent low-dose danazol therapy to limit side effects. In between these courses of hormone, nonpharmacologic and nonhormonal therapy can be used.
- Severe, unremitting mastodynia that does not respond to medical treatment may require mastectomy; this is rare.

DISPOSITION

- Cyclic mastodynia resolves spontaneously in 20% to 30% of women.
- Noncyclic mastodynia responds poorly to treatment but may resolve spontaneously in up to 50% of women.

AUTHOR: **Gina Ranieri, DO**

BASIC INFORMATION

DEFINITION

Mastoiditis is inflammation of the mastoid process and air cells, a complication of otitis media.

SYNONYM

Mastoid abscess

ICD-10CM CODES

H40.1 Chronic mastoiditis
H70.0 Acute mastoiditis
H70.8 Other mastoiditis and related conditions
H70.9 Mastoiditis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Since the introduction of antibiotic therapy and use of broad-spectrum antibiotics, there has been a marked decline in the incidence of acute mastoiditis.
PREDOMINANT SEX: More common in males
PREDOMINANT AGE: 2 mo to 18 yr
PEAK INCIDENCE: Early childhood

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Acute mastoiditis is usually a complication of acute otitis media.
- Most common presenting symptom is pain and tenderness in the postauricular region.
- Other signs or symptoms include:
  1. Fever
  2. Postauricular erythema and edema
  3. Protrusion of the pinna inferiorly and anteriorly
  4. Tympanic membrane usually intact with signs of acute otitis media
- Complications of acute mastoiditis include:
  1. Subperiosteal abscess (most common complication)
  2. Hearing loss
  3. Facial nerve palsy
  4. Labyrinthitis
  5. Intracranial complications such as hydrocephalus, meningitis, encephalitis, intracranial abscess, and lateral sinus thrombosis
- Chronic mastoiditis is characterized by chronic otorrhea and chronic tympanic membrane perforation.

ETIOLOGY

- Continuity exists between the middle air space and the mastoid cavity.
- Initial hyperemia and edema of the mucosal lining of the air cells result in accumulation of purulent exudate.
- Dissolution of calcium from bony septa and osteoclastic activity in the inflamed periosteum lead to bone necrosis and coalescence of air cells.
- Most common bacterial isolates (Table E1) are:
  1. *Streptococcus pneumoniae*
  2. *Streptococcus pyogenes*
  3. *Haemophilus influenzae*
  4. *Moraxella catarrhalis*
  5. *Staphylococcus aureus*
- Often, there are multiple organisms in chronic mastoiditis, with predominance of anaerobes and gram-negative bacteria.
- *Mycobacterium tuberculosis,* nontuberculous mycobacteria, *Aspergillus,* and *Rhodococcus equi* have been reported in cases of mastoiditis in severely immunocompromised individuals.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Children:
  1. Rhabdomyosarcoma
  2. Histiocytosis X
  3. Leukemia
  4. Kawasaki syndrome
- Adults:
  1. Fulminant otitis externa
  2. Histiocytosis X
  3. Metastatic disease
- Table E2 differentiates postauricular involvement of acute mastoiditis with periostitis/abscess.

WORKUP

A thorough history and physical examination are important in establishing diagnosis.

TABLE E1 Etiology of Acute Mastoiditis

Bacteria	Frequency
Streptococcus pneumoniae	10-51%
Streptococcus pyogenes	0-12%
Staphylococcus aureus	2-10%
Pseudomonas aeruginosa	10%
Haemophilus influenzae	2-3%
No growth	20-40%

From Kliegman RM: *Nelson Textbook of Pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

LABORATORY TESTS

- Fluid for Gram stain and culture may be obtained by myringotomy.
- If there is a perforation in the tympanic membrane with drainage, cultures of this may be taken after carefully cleaning the external canal.

IMAGING STUDIES

- Plain x-rays of the mastoid region may demonstrate clouding or opacification in areas of pneumatization.
- CT scan (Fig. E1) can demonstrate early involvement of bone (mastoiditis with bone destruction).
- MRI is more sensitive than CT scan in evaluating soft-tissue involvement and is useful in conjunction with CT scan to investigate other complications of mastoiditis.

TREATMENT

NONPHARMACOLOGIC THERAPY

Myringotomy, if the ear is not already draining

ACUTE GENERAL Rx

- Initiated with IV antibiotics directed against the common organisms *S. pneumoniae* and *H. influenzae.* Useful agents are amoxicillin/clavulanate, ceftriaxone, and cefotaxime. If the disease in the mastoid has had a prolonged course, coverage for *S. aureus* with gram-negative enteric bacilli may be considered for initial therapy until results of cultures become available. Add vancomycin if methicillin-resistant *Staphylococcus aureus* (MRSA) suspected or nafcillin/oxacillin if culture is positive for *S. aureus*, methicillin susceptible.
- Antibiotics continued until all signs of mastoiditis have resolved

TABLE E2 Differential Diagnosis of Postauricular Involvement of Acute Mastoiditis With Periostitis/Abscess

	Postauricular Signs and Symptoms				External Canal Infection	Middle-Ear Effusion
Disease	Crease*	Erythema	Mass	Tenderness		
Acute mastoiditis with periostitis	May be absent	Yes	No	Usually	No	Usually
Acute mastoiditis with subperiosteal abscess	Absent	Maybe	Yes	Yes	No	Usually
Periostitis of pinna with postauricular extension	Intact	Yes	No	Usually	No	No
External otitis with postauricular extension	Intact	Yes	No	Usually	Yes	No
Postauricular lymphadenitis	Intact	No	Yes†	Maybe	No	No

*Postauricular crease (fold) between pinna and postauricular area.
†Circumscribed.
From Bluestone CD, Klein JO, eds: *Otitis media in infants and children*, ed 3, Philadelphia, 2001, WB Saunders, p 333. In Kliegman RM: *Nelson Textbook of Pediatrics*, ed 21, Philadelphia, 2020, Elsevier.

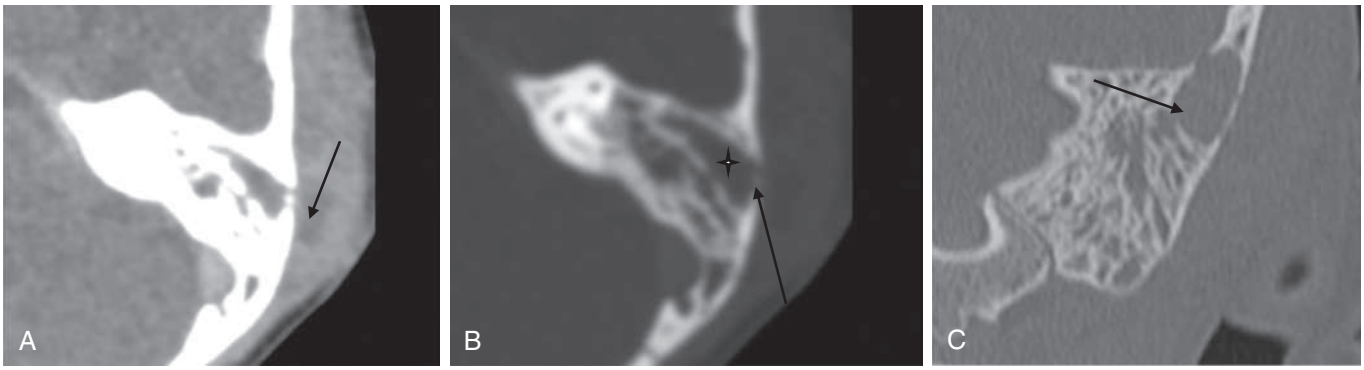

FIG. E1 This contrasted CT scan shows coalescent mastoiditis with subperiosteal abscess formation. Panels **A** and **B** contain axial images with soft tissue windows and bone windows, respectively. In panel **A**, the *arrow* points to the subperiosteal abscess. The *star* in panel **B** shows the loss of bony septations in the mastoid cavity and the *arrow* points to the erosion of the bony cortex. Panel **C** is a coronal image showing demineralization of the mastoid tegmen abutting the middle cranial fossa. The image in panel **C** is a precursor to epidural abscess formation. (From Kliegman RM: *Nelson Textbook of Pediatrics*, ed 21, Philadelphia, 2020, Elsevier.)

- Directed against enteric gram-negative organisms and anaerobes in chronic mastoiditis
- Indications for mastoidectomy:
  1. Failure to improve after 72 hr of therapy
  2. Persistent fever
  3. Imminent or overt signs of intracranial complications
  4. Evidence of a subperiosteal abscess in the mastoid bone

DISPOSITION

Proceed with mastoidectomy when medical therapy fails.

REFERRAL

- To otorhinolaryngologist:
  1. If diagnosis is in doubt
  2. If aural complications present
  3. To evaluate for surgical intervention
- To neurosurgeon if intratemporal or intracranial extension of infection suspected:
  1. Aural complications: Bone destruction, subperiosteal abscess, petrositis, facial paralysis, labyrinthitis
  2. Intracranial complications: Extradural abscess, lateral sinus thrombophlebitis or thrombosis, subdural abscess, meningitis, brain abscess, otitic hydrocephalus

PEARLS & CONSIDERATIONS

Mastoiditis is particularly difficult to eradicate because the mastoid air cells are poorly vascularized and difficult to drain.

BASIC INFORMATION

DEFINITION

Measles is a childhood exanthem caused by an RNA virus called *Morbillivirus,* belonging to the family Paramyxoviridae.

SYNONYM

Rubeola

ICD-10CM CODES

B05.0	Measles complicated by encephalitis
B05.1	Measles complicated by meningitis
B05.2	Measles complicated by pneumonia
B05.3	Measles complicated by otitis media
B05.4	Measles with intestinal complications
B05.81	Measles keratitis and keratoconjunctivitis
B05.89	Other measles complications
B05.9	Measles without complication
Z23	Encounter for immunization

EPIDEMIOLOGY & DEMOGRAPHICS

- Before the introduction of an effective vaccine in 1963, measles was one of the most common childhood illnesses. In developing countries, where it mostly strikes children <5 yr, it remains a leading cause of childhood death.
- Although measles was eliminated in the United States in 2000 (Fig. E1), vaccine hesitancy and importation of the virus from other countries continues to cause outbreaks.
- In developed countries, measles outbreaks occasionally occur in adolescents and young adults who have not been immunized (incidence up to 10 per 100,000 person/yr).

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Incubation: 10 to 14 days (up to 3 wk in adults)
- Prodrome: 2 to 4 days; malaise, fever, rhinorrhea, conjunctivitis, cough
- Exanthem phase: 7 to 10 days
- The fever increases and peaks at 104° to 105° F together with the rash; it persists for 5 or 6 days. The patient's fever decreases over 24 hr
- Rash: Erythematous maculopapular eruption begins behind the ears, progresses to the forehead and neck, then spreads to face, trunk (Fig. E2, Fig. E3), upper extremities, buttocks, and lower extremities, in that order. After 3 days the rash fades in the same sequence by becoming copper brown and then desquamating
- Enanthem: *Koplik spots* are white papules 1 to 2 mm in diameter on an erythematous base. They first appear on the buccal mucosa opposite the lower molar 2 days before the rash and spread over 24 hr to involve most of the buccal and lower labial mucosa (Fig. E4). They fade after 3 days
- Other symptoms and signs: Malaise, anorexia, vomiting, diarrhea, abdominal pain, pharyngitis, lymphadenopathy, and occasional splenomegaly

Atypical measles (in vaccinated persons):

- Incubation: 10 to 14 days
- Prodrome: 1 to 3 days; high fever and headache
- Rash: Maculopapular, urticarial, or petechial rash that begins peripherally and progresses centrally
- Modified measles applies to patients who have received immune serum globulin and develop a milder illness
- Complications (30% of all cases):
  1. Otitis media
  2. Laryngitis, tracheitis
  3. Pneumonia (accounts for 90% of measles deaths)
  4. Encephalitis with lethargy, irritability, and seizures; 60% recover completely, 25% have neurologic sequelae (mental retardation, hemiplegia, paraplegia, epilepsy, deafness), and 15% die
  5. Myocarditis, pericarditis, hepatitis
  6. Complications more common in immunocompromised hosts and persons with AIDS

ETIOLOGY & PATHOGENESIS

- The measles virus is transmitted through the respiratory tract by airborne droplets. Patients shed measles virus from 7 days after exposure to 4 to 6 days after the onset of rash.
- Measles is one of the most contagious human pathogens. A single case of human measles results in 12 to 18 secondary cases in a susceptible population.
- It initially infects the respiratory epithelium; the patient becomes viremic during the prodromal phase, and the virus is disseminated to the skin, respiratory tract, and other organs.
- Generally patients with measles are infectious from 4 days before to 4 days after the onset of a rash.
- Viral clearance is achieved by cellular immunity.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Other viral infections by enteroviruses, adenoviruses, human parvovirus B-19, rubella (Table E1)
- Scarlet fever
- Allergic reaction
- Kawasaki disease

WORKUP

Knowledge of outbreak, history, and physical findings (Koplik spots are diagnostic), laboratory tests

LABORATORY TESTS

- Enzyme-linked immunosorbent assay for measles antibodies, which appear shortly after the onset of the rash and peak 3 to 4 wk later
- Complete blood count: Leukopenia
- Cerebrospinal fluid analysis in encephalitis may reveal pleocytosis (lymphocytes) and an elevated protein

IMAGING STUDIES

Chest radiograph if pneumonia is suspected

TREATMENT

- Supportive (hydration, antipyretics for comfort and fever control, airway humidification in patients with respiratory tract involvement). Antiviral therapy is not effective.

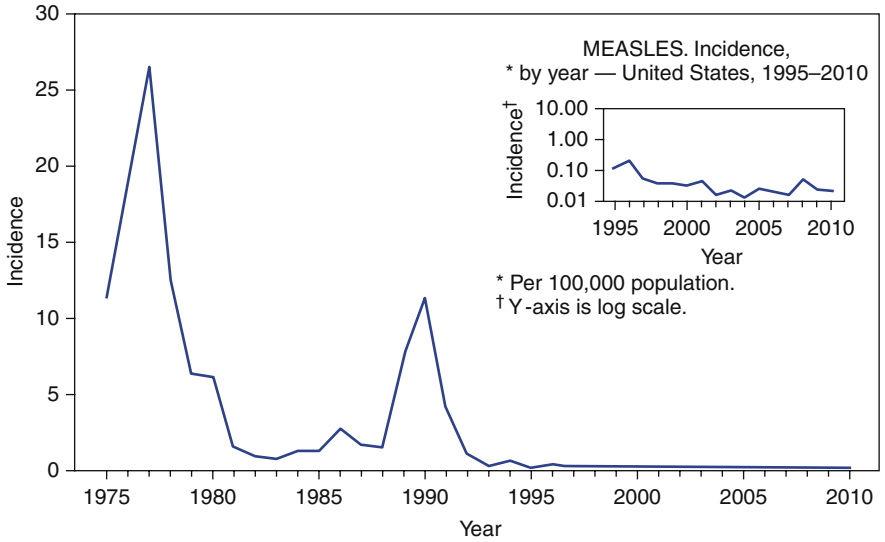

FIG. E1 Incidence by yr—U.S., 1975 to 2010. (From Centers for Disease Control and Prevention: Summary of notifiable diseases—United States, *MMWR Morb Mortal Wkly Rep* 59(53):1-111, 2012.)

FIG. E3 Rubeola (measles). Intensely erythematous patches of the face with cephalocaudad spread onto the trunk and extremities. (From Paller AS, Mancini AJ: *Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, 2016, Elsevier.)

FIG. E4 Koplik spots on the buccal mucosa during the third day of rash. (From Centers for Disease Control and Prevention: Public Health Image Library, Image #4500, available at http://phil.cdc.gov/phil/details.asp.)

TABLE E1 A Guide to the Differential Diagnosis of Measles

	Conjunctivitis	Rhinitis	Sore throat	Exanthem	Leukocytosis	Specific Laboratory Tests
Measles	++	++	0	+	0	+
Rubella	0	±	±	0	0	+
Exanthem subitum	0	±	0	0	0	+
Enterovirus infection	0	±	±	0	0	+
Adenovirus infection	+	+	+	0	0	+
Scarlet fever	±	±	++	0	+	+
Infectious mononucleosis	0	0	++	±	±	
Drug rash	0	0	0	0	0	0

From Gabbe SG: *Obstetrics,* ed 6, Philadelphia, 2012, WB Saunders.

- Vitamin A therapy is beneficial in children >6 mo of age with measles who are hospitalized with measles and its complications or have any of the following risk factors: immunodeficiency, clinical evidence of vitamin A deficiency, impaired intestinal absorption, moderate to severe malnutrition, and recent immigration from areas where high mortality rates attributed to measles have been observed. Treatment regimen consists of a single dose of 200,000 IU orally for children >1 yr of age, 100,000 IU for children 6 mo to 1 yr of age and 50,000 IU for infants younger than 6 mo.
- Ribavirin is at times used for severe measles pneumonitis; however, it is not licensed in the U.S. for treatment of measles.
- Post-exposure prophylaxis: Measles vaccine given within 3 days after measles exposure, or human immune globulin given up to 6 days after exposure, can prevent or attenuate disease in susceptible persons.

PEARLS & CONSIDERATIONS

PREVENTION

- Passive immunization: Human immunoglobulin 0.5 ml/kg of body weight IM for persons weighing up to 30 kg and a dose of 400 mg/kg IU for persons of body weight OVER 30 kg
- Active immunization (see Section V).

Measles (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

SUGGESTED READING

Gastañaduy PA et al: A measles outbreak in an underimmunized Amish community in Ohio, *N Engl J Med* 375:1343-1354, 2016.

Strebel PM, Orenstein WA: Measles, *N Engl J Med* 381(4):349-357, 2019.

BASIC INFORMATION

DEFINITION

Meckel diverticulum is an ileal diverticulum located 100 cm proximal to the cecum. It results from failure of the omphalomesenteric duct to obliterate completely (as it should by the eighth wk of gestation).

SYNONYM

MD

ICD-10CM CODES

Q43.0	Meckel diverticulum (displaced) (hypertrophic)
C17.3	Meckel diverticulum, malignant

EPIDEMIOLOGY & DEMOGRAPHICS

- Meckel diverticulum, based on autopsy studies and intraoperative evidence, occurs in 0.3% to 4% of the population and is the most prevalent congenital anomaly of the gastrointestinal (GI) tract. Complications occur more frequently in males.
- Most patients who develop symptoms are <10 yr.
- The lifetime risk of complications developing in a case of Meckel diverticulum is 4%.
- In adults, complications (small bowel obstruction [25% to 40%], diverticulitis [20%]) are usually attributable to factors other than heterotopic mucosa.
- Tumors have rarely been reported in symptomatic Meckel diverticulum, with carcinoid being the most common type.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Painless lower GI bleeding (4%)
- Intestinal obstruction caused by intussusception, volvulus, herniation, or entrapment of a loop of bowel through a defect in the diverticular mesentery (6%)
- Meckel diverticulitis mimics acute appendicitis (5%)
- Rare primary tumor arising from diverticulum (carcinoid, sarcoma, leiomyoma, adenocarcinoma)
- Asymptomatic (80% to 95%)

ETIOLOGY & PATHOGENESIS

- As a remnant of the omphalomesenteric duct, Meckel diverticulum contains all layers of the intestinal wall and has its own mesentery and blood supply (branch of the superior mesenteric artery) (Fig. E1).
- The majority of complicated cases of Meckel diverticulum contain ectopic mucosa (75% gastric, 15% pancreatic). It causes ulceration and bleeding of ileal mucosa adjacent to the acidic ectopic gastric secretions. Alkaline secretions of ectopic pancreatic tissue can also cause ulcerations.

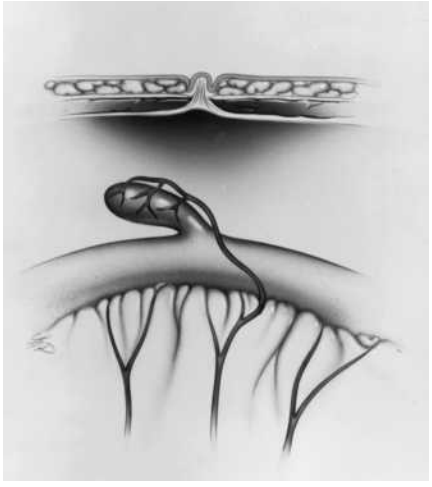

FIG. E1 Typical Meckel diverticulum located on the antimesenteric border. (From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, WB Saunders.)

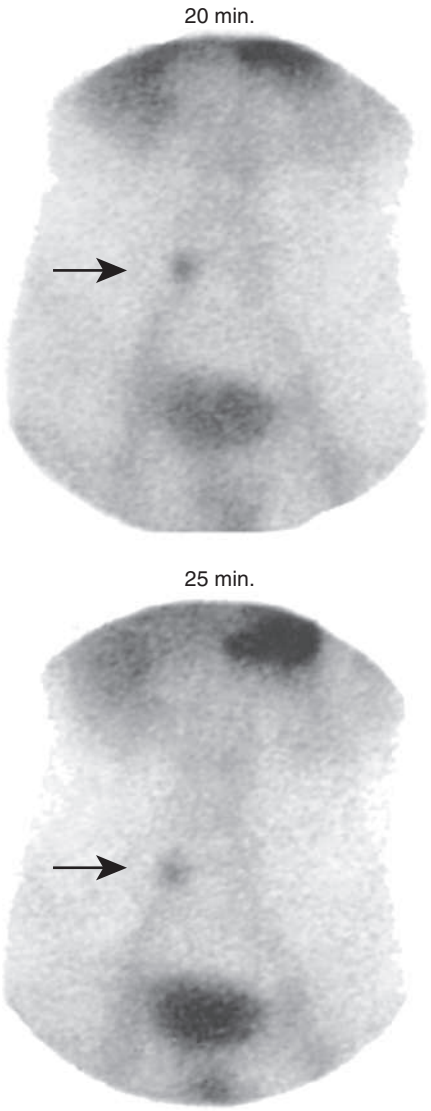

FIG. E2 Meckel scan demonstrating accumulation in the stomach superior bladder (inferior) and in the acid-secreting mucosa of a Meckel diverticulum. (From Kliegman RM et al: *Nelson textbook of pediatrics,* ed 19, Philadelphia, 2011, WB Saunders.)

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Appendicitis
- Crohn disease
- All causes of lower GI bleeding (polyp, colon cancer, arteriovenous malformation, diverticulosis, hemorrhoids)

WORKUP

- Diagnosis is often made intraoperatively when the preoperative diagnosis is appendicitis.
- Preoperative detection of symptomatic Meckel diverticulum requires a high index of suspicion.
- Meckel scan: In the case of GI bleeding of unknown source, a technetium scan will identify Meckel diverticulum (sensitivity: 85% in children, 62% in adults; specificity: 95% in children, 9% in adults) (Fig. E2).
- In patients with suspected small-bowel obstruction, intussusception, or diverticulitis, a CT scan of the abdomen and pelvis is helpful.

TREATMENT

- Surgical resection in symptomatic patients.
- There is controversy regarding the need to remove an incidentally found diverticulum, with most surgeons arguing in favor of resection.

RELATED CONTENT

Meckel Diverticulum (Patient Information)

AUTHOR: **Fred F. Ferri, MD**

BASIC INFORMATION

DEFINITION

Mediastinitis is an infection involving the connective mediastinal tissue that fills the interpleural spaces and surrounds the mediastinal organs. It can be acute or chronic.

SYNONYMS

Fibrosing mediastinitis
Sclerosing mediastinitis
Granulomatous mediastinitis

ICD-10CM CODE
J98.5 Mediastinitis

EPIDEMIOLOGY

Acute mediastinitis (Box 1) occurs most frequently as a postoperative infection after a median sternotomy and can be a life-threatening infection. Most infections are bacterial in nature.

Chronic mediastinitis is a chronic form of infection in the mediastinum characterized by an invasive and compressive inflammatory infiltrate. It is mostly caused by fungi and some bacteria.

INCIDENCE: Incidence of postoperative mediastinitis ranges from 0.4% to 5%.

RISK FACTORS: Mediastinal infections have four possible sources:

- Direct contamination as seen in trauma or surgery (e.g., open heart, esophageal)
- Hematogenous or lymphatic spread
- Extension of infection from the neck or retroperitoneum
- Extension from the lung, pleura, or chest wall

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Patients with acute mediastinitis present with acute onset of fever, tachycardia, chest pain, dysphagia, or respiratory distress. There may be signs of sternal wound infection or cellulitis and/or crepitus and edema of the chest wall.
- Patients with chronic mediastinitis are mostly asymptomatic until symptoms develop related to invasion or obstructions of structures within the mediastinum or adjacent to the mediastinum, such as cough, dyspnea, wheezing, chest pain, dysphagia, or hemoptysis. Complications of chronic or sclerosing mediastinitis include:
  1. Superior vena cava syndrome. Histoplasma is the most common nonmalignant cause of this syndrome, marked by edema of face, neck and torso; neck vein distention; and headache
  2. Pulmonary venous or arterial obstruction
  3. Esophageal obstruction, cor pulmonale, constructive pericarditis
  4. Thoracic duct obstruction

BOX 1 Classification of Mediastinitis

Acute Mediastinitis
- A. Due to traumatic perforation of the esophagus
  1. Spontaneous or postemetic
  2. Foreign body–associated
  3. Instrumentation or surgery
- B. Due to extension of infection from adjacent structures
  1. Infection of the head and neck
  2. Infections of lungs, pleura, lymph nodes, or pericardium
  3. Subphrenic infection
  4. Vertebral osteomyelitis
  5. Hematogenous dissemination
- C. Postoperative

Chronic Mediastinitis

From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

ETIOLOGY (TABLE 1)

Acute mediastinitis:

- Related to head and neck infections or esophageal perforation
  1. Anaerobic bacteria: *Peptostreptococci, Veillonella, Fusobacterium, Actinomyces, Prevotella, Eubacterium, Bacteroides*
  2. Aerobic bacteria: *Streptococcus, Staphylococcus, Corynebacterium, Moraxella*, enteric gram-negative rods
  3. Fungi: *Candida albicans*
- Related to cardiothoracic surgery
  1. Gram-positive bacteria: *Staphylococcus aureus, Staphylococcus epidermidis, Enterococcus, Streptococcus*
  2. Gram-negative bacteria: *Escherichia coli, Enterobacter, Klebsiella, Proteus, Pseudomonas*, other Enterobacteriaceae
  3. Fungi: *Candida albicans*

Chronic mediastinitis:

- *Histoplasma capsulatum,* a dimorphic fungus, is the most common and can cause mediastinal granuloma or fibrosing mediastinitis. A leakage of fungal antigens from lymph nodes into the mediastinal space is believed to cause a hypersensitivity reaction and subsequent exuberant fibrotic response.
- Other: *Mycobacterium tuberculosis, Nocardia,* actinomycosis, aspergillosis.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

For chronic mediastinitis:

- Tumors that can also cause superior vena cava syndrome (e.g., Hodgkin and non-Hodgkin lymphomas, mesothelioma)
- Sarcoidosis
- Behçet syndrome
- Mediastinal fibrosis associated with radiation
- Silicosis

LABORATORY TESTS

- CBC with differential, C-reactive protein, and procalcitonin can point to bacterial infection
- Obtain cultures: Aerobic and anaerobic bacteria and fungi, intraoperatively or of any purulent drainage
- Pathologic examination: Distinguish between cancer and infection for chronic mediastinitis and allow for specific fungal stains on tissues

IMAGING STUDIES

- Chest x-ray: Can show diffuse mediastinal widening or evidence of mediastinal abscess, including gas bubbles or fluid level. Pneumomediastinum (Fig. E1) or pneumothorax can be seen with esophageal perforation (Table 2).

TABLE 1 Microbiology of Mediastinitis

Organisms Frequently Recovered in Mediastinitis Secondary to Infection of the Head and Neck or Esophageal Perforation

Anaerobic

Gram-positive cocci—*Peptostreptococcus* spp.
Gram-positive bacilli—*Actinomyces, Eubacterium, Lactobacillus*
Gram-negative cocci—*Veillonella*
Gram-negative bacilli—*Bacteroides* spp., *Fusobacterium* spp., *Prevotella* spp., *Porphyromonas* spp.

Aerobic or Facultative

Gram-positive cocci—*Streptococcus* spp., *Staphylococcus* spp.
Gram-positive bacilli—*Corynebacterium*
Gram-negative cocci—*Moraxella*
Gram-negative bacilli—Enterobacteriaceae, *Pseudomonas* spp., *Eikenella corrodens*
Fungi—*Candida albicans*

Representative Organisms Recovered in Mediastinitis Secondary to Cardiothoracic Surgery, with Representative Rate and Range

Gram-Positive Cocci

Staphylococcus aureus, 25% (7.1%-66.7%)
Staphylococcus epidermidis, 30% (6%-45.5%)
Enterococcus spp., 10% (8%-18.8%)
Streptococcus spp., 2% (0%-18.2%)

Gram-Negative Bacilli

Escherichia coli, 5% (0%-12.5%)
Enterobacter spp., 10% (4%-21.4%)
Klebsiella spp., 3% (0%-21.1%)
Proteus spp., 2% (0%-7.1%)
Other Enterobacteriaceae, 2% (0%-20%)
Pseudomonas spp., 2% (0%-54%)

Fungi

C. albicans, <2 (0%-20.5%)
Polymicrobial, 10% (0%-40%)

Others Occasionally Reported

Acinetobacter, Salmonella spp., *Legionella* spp., *Bacteroides fragilis, Corynebacterium* spp., *Burkholderia cepacia, Mycoplasma hominis, Candida tropicalis, Aspergillus* spp., *Nocardia* spp., *Kluyvera, Gordonia sputi, Mycobacterium fortuitum, Mycobacterium chelonae, Rhodococcus bronchialis*

Other Unusual Causes of Mediastinitis

Anthrax, brucellosis, actinomycosis, paragonimiasis, *Streptococcus pneumonia*

From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.

TABLE 2 Risk Factors for Surgical Site Infection/Mediastinitis Post–Cardiac Surgery

Preoperative Risk Factors	Operative Risk Factors	Postoperative Risk Factors
Increasing age	Emergent surgery	Need for reexploration
Diabetes	Heart transplant	Prolonged ICU stay
Staphylococcus aureus nasal colonization	Increasing complexity of surgery	Need for mechanical ventilation >48 hr
Previous sternotomy	Use of internal thoracic arteries in CABG	Lack of perioperative glucose control
COPD	Prolonged operative time	Placement of tracheostomy
Peripheral vascular disease	Hair removal by razor, not clippers	Postoperative myocardial infarction
Class 3-4 angina	Inappropriate timing of antibiotics	Receipt of multiple blood products
Renal failure requiring hemodialysis	Prolonged time on cardiopulmonary bypass	Postoperative low cardiac output state
History of endocarditis	High core temperature during bypass (>38° C; 100.4° F)	
Cigarette smoking		
Low cardiac output		
Concurrent infection		
Prolonged preoperative hospitalization		
Preoperative use of a ventricular assist device		

CABG, Coronary artery bypass grafting; *COPD,* chronic obstructive pulmonary disease; *ICU,* intensive care unit.
From Bennett JE et al: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, WB Saunders.

- Chest CT (Fig. E2): Can show the same as x-ray but is more sensitive in determining degree of mediastinal involvement and may guide drainage procedures for treatment or diagnosis.
- MRI may be superior to CT for sclerosing mediastinitis.

Rx TREATMENT

NONPHARMACOLOGIC THERAPY

Surgery remains the gold standard treatment of mediastinitis for optimal drainage and debridement.

- Open techniques: Debridement of infected tissue and open packing of the wound with delayed closure or use of vacuum-assisted closure for acute mediastinitis
- Closed techniques: Debridement of infected tissues, closure of the sternum, and postoperative irrigation through drainage tubes for acute mediastinitis

ACUTE GENERAL Rx

- Intravenous antibiotics: Also a cornerstone of therapy but without surgery may fail. Broad-spectrum antibiotics should be used until cultures are finalized. Combination of piperacillin-tazobactam or meropenem plus vancomycin offers good initial coverage for acute mediastinitis. Other options include ciprofloxacin or cefepime for gram-negative rods, linezolid for gram-positive bacteria, metronidazole for anaerobic bacteria.
- Therapy is 2 to 3 wk, but some cases may require 4 to 6 wk.

CHRONIC Rx

There is no definitive cure for chronic fibrosing or sclerosing mediastinitis. Antifungal agents and steroids generally do not work. The goal of therapy is to palliate symptoms by relieving airway, vascular, or esophageal obstruction. Surgery in patients with extensive fibrosis has high morbidity and mortality.

DISPOSITION

Patients may need extensive wound care and possible vacuum-assisted closure and prolonged intravenous antibiotics.

REFERRAL

- Thoracic surgeon and/or head and neck surgeon for surgery and debridement
- Infectious diseases consultant for antibiotic selection and long-term management

PEARLS & CONSIDERATIONS

COMMENTS

Histoplasma capsulatum is a dimorphic fungus found commonly in bird and bat fecal material and is most prevalent in the Ohio and Mississippi river valleys of the United States.

PREVENTION

Antibiotic prophylaxis should be given within 60 min before incision for surgeries requiring sternotomy. Options include cefazolin 1 g IV if <80 kg and 2 g if >80 kg, or cefuroxime 1.5 g IV. If the patient is penicillin allergic or has a history of methicillin-resistant *S. aureus* (MRSA) infection or surgery is to be done in a hospital where MRSA infection is common, use vancomycin 1 g IV.

Medical Marijuana

BASIC INFORMATION

DEFINITION

Medical cannabis refers to the use of the unprocessed marijuana plant or part of the plant or extracts from the marijuana plant as medical therapy to treat disease or alleviate symptoms.

SYNONYMS

Medical cannabis
Cannabinoids—are biologically active compounds that have affinity or activity to the cannabinoid receptors. They may be derived from the plant or be synthetic.
CBD—cannabinol
THC—Δ^9 -tetrahydrocannabinol

ICD-10CM CODES

F12.9	Cannabis use, unspecified
Z02.79	Encounter for issue of other medical certificate
Z79.899	Other long term (current) drug therapy

BACKGROUND

- First medical marijuana law (MML) was enacted in California in 1996, allowing for use of medical cannabis despite lack of Food and Drug Administration (FDA) testing for safety and efficacy.
- In 2014, 0.8% of the U.S. population used medical marijuana exclusively, and 0.5% used medical and recreational marijuana.
- Of 2014 marijuana smokers, 6.2% used medical marijuana only and 3.6% used medical and recreational marijuana.
- In 2015, 1.57% U.S. population used medical marijuana; highest increase in prevalence noted to be in 2015.
- Residents of medical marijuana states were 1.3 times more likely to use medical marijuana in 2015 compared to 2013.
- As of July 2019, state-level referendum and legislation resulted in 33 U.S. states, DC, Guam, and Puerto Rico with policies that legalized marijuana use for medical purposes.

MECHANISM OF ACTION

- Cannabinoids elicit their effects by interacting with cannabinoid receptors in various central nervous system (CNS) locations, eliciting diverse CNS and peripheral nervous system (PNS) effects.
- Primarily bind to CB1 G-protein-coupled receptors in the basal ganglia, hippocampus, cortex, and cerebellum, eliciting antinociception, locomotor, and psychoactive effects.
- Marijuana contains roughly 60 plant-derived cannabinoid compounds, with the major phytocannabinoids being cannabidiol (CBD) and Δ^9-tetrahydrocannabinol (THC).

FORMULATIONS

Research has demonstrated a wide range of THC and CBD concentrations in various formulations, with frequent inaccurate labelling.

- Cigarettes
- Tinctures
- Capsules
- Vaporization cartridges
- Purified cannabinoids butane hash oil
- Supercritical fluid extracts (SFEs or "dabs")
- Buccal sprays
- Edibles
- Lozenges
- Transdermal patches

INDICATIONS

- Variable evidence for treatment of:
  1. Chronic pain
  2. Chemotherapy-induced nausea/vomiting
  3. HIV-related anorexia
  4. Glaucoma
  5. Anxiety
  6. Multiple sclerosis (MS)
  7. Seizures
- Marijuana has not been FDA approved as safe and effective for any indication and remains a Schedule I drug.
- However, there are phytocannabinoids and synthetic phytocannabinoid analogs that are FDA approved.
  1. Dronabinol and Nabilone (synthetic THC analogs) are schedule II FDA approved medications for AIDS associated anorexia and chemotherapy induced nausea, respectively.
  2. Purified cannabidiol oral solution (Epidiolex) is FDA approved for seizures associated with Dravet or Lennox-Gastaut syndrome.
- Qualifying diagnoses for certification for prescription medical marijuana vary by state, but typically include:
  1. Cancer
  2. Glaucoma
  3. HIV/AIDS
  4. Hepatitis C
  5. Cachexia
  6. Severe, debilitating, chronic pain
  7. Severe nausea
  8. Seizures
  9. Severe muscle spasms
  10. Crohn disease
  11. Alzheimer disease
  12. PTSD
  13. Sickle cell disease

EFFICACY

- There is evidence in the medical literature demonstrating that marijuana improves non–cancer-related pain, chemotherapy-induced nausea and vomiting, and spasticity in multiple sclerosis.
  1. A 2011 systematic review of randomized controlled trials (RCTs) demonstrated statistically significant improvement in pain scores for non–cancer-related chronic pain in 15 of 18 trials with no serious adverse effects.
  2. A 2015 systematic review and meta-analysis showed improved response in nausea and vomiting compared to placebo (OR 3.82).
  3. A 2018 systematic review demonstrated a decrease in nausea and vomiting following chemotherapy (RR 3.60 compared to placebo), improved spasticity with MS (RR 1.45 compared to placebo), and a modest benefit with primarily neuropathic pain (RR 1.37 compared to placebo) with frequent adverse effects including psychosis, "feeling high," and somnolence (number needed to harm = 5 to 8).
     a. No statistically significant improvement was noted in acute pain.
  4. A Cochrane review in 2013 found no statistically significant weight gain with dronabinol in HIV/AIDS patients, and multiple RCTs have identified megestrol acetate as superior to dronabinol for weight gain in cancer patients.

RISKS OF USE

- Marijuana use has been demonstrated to impair short-term memory consolidation, reaction time, and concept formation, and to increase incidence of road traffic accidents, ataxia, euphoria, disorientation, dry mouth, somnolence, and, at high doses, psychosis, panic, and paranoia.
- Meta-analyses demonstrate increased respiratory symptoms of cough, sputum production, and wheeze with smoking marijuana; however, there was no statistical difference in pulmonary function.
- Concomitant use of other medications such as opiates and benzodiazepines should be avoided as it could lead to somnolence and respiratory suppression.
- Acute marijuana intoxication is associated with reversible changes in P and T waves and ST segments (pseudo-Wellens syndrome).[1]
- Medical marijuana should be stored away from children given the risk of toxic ingestion.

PRESCRIBING

- Marijuana remains classified as a schedule I drug under the Controlled Substance Act of 1970.
- However, the Justice Department declared it would not prosecute any physician who recommends medical marijuana for a legitimate medical indication in a state where it has been legalized.
- Medical marijuana card (MMC)
  1. MMC allows a patient to possess a certain amount of marijuana for medical use and not be prosecuted for possession of marijuana.
  2. In order to obtain an MMC, a patient must obtain physician certification confirming a clinical indication for medical marijuana.
  3. With an MMC, the patient can go to a licensed medical marijuana compassion center (dispensary), which will dispense a dose and formulation of medical marijuana appropriate for the patient's medical condition.
  4. Physicians do not prescribe the dose or formulation of medical marijuana.
- To certify a patient for a medical marijuana card, physicians must

[1]Co MLF et al: Pseudo-Wellens syndrome after heavy marijuana use, *Cleve Clin J Med* 84(8):590-591, 2017.

1. Complete a Department of Health certification form.
   a. Forms vary by state, but typically consist of a single-page form indicating a qualifying diagnosis that is to be signed by the physician.
2. Complete and document a full medical history and physical exam.
3. Explain the risks, benefits, and side effects of medical marijuana.
4. Continue an ongoing role on the patient's health care team.
5. Maintain accurate medical records and documentation of the patient's clinical indication for medical marijuana.

- Some states require additional physician training and registration with the state medical marijuana program prior to being able to certify patients.
- Physicians are under no obligation to issue medical marijuana certifications.

PEARLS & CONSIDERATIONS

- Medical marijuana has been shown to improve non–cancer-related pain, chemotherapy-induced nausea and vomiting, and spasticity in multiple sclerosis.
  1. However, qualifying diagnoses for a medical marijuana card include cancer, glaucoma, HIV/AIDS, hepatitis C, cachexia, debilitating chronic pain, severe nausea, seizures, severe muscle spasms, Crohn disease, Alzheimer disease, PTSD, and sickle cell disease. Qualifying diagnoses may vary from state to state.
  2. Adverse effects include increased incidence of road traffic accidents and pulmonary and cognitive side effects. At high doses, psychosis, panic, and paranoia can occur.
  3. Hospitals may also have specific restrictions and policies regarding medical marijuana for inpatient stays.
- Medical marijuana laws and regulations permit patients to use medical marijuana if certified by a physician but vary by state.
  1. Physician certification involves documentation that a patient has a qualifying clinical condition.
  2. A medical marijuana card entitles a patient or designated caregiver to possess a given amount of marijuana and therefore will not be prosecuted for possession of marijuana.
  3. Medical marijuana can be obtained at state regulated medical marijuana compassion centers (dispensaries). Compassion centers obtain marijuana from licensed cultivators and offer a variety of formulations that are regulated by the state.
  4. There is no FDA oversight of the compassion centers.
- Physicians do not prescribe the dose or formulation of medical marijuana.
- Physicians are under no obligation to issue medical marijuana certifications.
- Emergency department (ED) visits attributable to inhaled cannabis are more frequent than those attributable to edible cannabis, although the latter is associated with more acute psychiatric visits and more ED visits than expected.[2]

PATIENT & FAMILY EDUCATION

- Patients must possess a valid state-issued ID and apply for a state medical marijuana card.
- Patients can obtain medical marijuana from compassion centers without a medical marijuana card but could then be prosecuted for possession of marijuana.
- Patients should be aware that concomitant use of other medications such as opiates and benzodiazepines should be avoided as it could lead to somnolence and respiratory suppression.
- Patients should store medical marijuana away from children given the risk of toxic ingestions.

Medication-Related Osteonecrosis of the Jaw

BASIC INFORMATION

DEFINITION

The American Association of Oral and Maxillofacial Surgeons (AAOMS) defines bisphosphonate-related osteonecrosis of the jaw (BRONJ) as an exposure of bone in the maxillofacial region that does not heal within 8 wk, in patients receiving therapeutic doses of bisphosphonates (BPs) who have not undergone radiation therapy to the craniofacial region and who do not have evidence of metastatic disease in the jaw. Osteoclast apoptosis may occur due to the antiresorptive effects of BPs, preventing the release of bone-regenerative proteins and thus preventing bone renewal and remodeling. This results in tissue loss and exposed bone. BRONJ primarily involves the jawbone due to its higher risk for complications from minor injury and infection when the healing potential or vascular supply is compromised.

Cases of ONJ have also been reported in patients receiving denosumab as well as chemotherapeutic and immunosuppressive agents, such as bevacizumab, sirolimus, sorafenib, and sunitinib. The AAOMS therefore uses the term medication-related osteonecrosis of the jaw (MRONJ).

SYNONYMS

Bisphosphonate-induced osteonecrosis of the jaw (BIONJ)
Medication-related osteonecrosis of the jaw (MRONJ)
Antiresorptive agent-related osteonecrosis of the jaw (ARONJ)
Denosumab-related osteonecrosis of the jaw (DRONJ)

ICD-10CM CODE
M87.180 Osteonecrosis due to drugs, jaw

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- A 2015 systematic review and consensus of 14 national and international societies describe the incidence of BRONJ in patients receiving oral BPs for the treatment of osteoporosis as 1.04 to 69 per 100,000 patient-yrs. The incidence of BRONJ in patients receiving intravenous (IV) BPs ranged from 0 to 90 per 100,000 patient-yrs.
- BRONJ has been estimated at 3.9% with oral BPs and at 14.8% with IV BPs at 42 mo after tooth extraction.
- DRONJ has been estimated at 0.68% in patients with postmenopausal osteoporosis who underwent invasive oral procedures vs. 0.05% for those who did not. The overall exposure-adjusted rate of DRONJ was 5.2 per 10,000 patient-yrs.

PEAK INCIDENCE:

- BRONJ has been identified as early as 7 mo after the use of IV BPs in patients with malignancy and as early as 13 mo in patients with osteoporosis. Incidence may depend on when dentoalveolar surgery occurs during BP treatment.
- A 2017 retrospective secondary analysis of 349 patients made the following estimates of median time to onset for 50% of patients to develop BRONJ: (1) 6 yr for those treated with oral alendronate, (2) 2.2 yr for those treated with IV zoledronate, (3) 5.3 yr for patients with osteoporosis, and (4) 2.2 yr for those with malignancy.
- A 2016 case series of 13 patients with malignancy receiving denosumab and with no history of BP treatment reported that DRONJ occurred after 5 to 36 doses of denosumab 120 mg subcutaneous every 4 to 6 wk.

PREVALENCE:

- Prevalence in 2008: estimated 13.3% of patients with malignancy receiving an IV BP.
- Most prevalent in patients with multiple myeloma or breast cancer versus other cancers or osteoporosis.

PREDOMINANT SEX AND AGE:

- Sex not statistically associated with MRONJ.
- Age as a risk factor for adults is variably reported in the literature.

GENETICS:

- Single nucleotide polymorphisms have been identified in the *CYP2C8* gene among patients with multiple myeloma and exposure to IV BPs.
- Polymorphisms in the *RBMS3* gene in white patients of European descent have been associated with a nearly six fold increase in the risk of developing BRONJ.
- A 2014 study of patients in Taiwan who received alendronate estimated an incidence rate of 283 per 100,000 person-yrs, suggesting a higher incidence in this ethnic group.

RISK FACTORS:

- Patients with malignancy who are exposed to IV BPs and undergo dentoalveolar surgery have an estimated five- to twenty-one fold increased risk for BRONJ compared with similar patients who do not undergo this surgery
- The 2014 AAOMS position paper estimates that the risk of MRONJ is about 100 times greater for patients with malignancy who receive antiresorptive agents versus patients with osteoporosis
- With IV formulations such as zoledronic acid, the risk ratio for developing BRONJ is 14.6 with IV versus oral products
- Longer duration of antiresorptive therapy
- Concomitant antiangiogenic agents and corticosteroids
- History of periodontal and dental abscesses
- Trauma due to invasive oral procedures such as tooth extractions
- Bacterial infection
- Chronic inflammation
- Poor oral hygiene
- Smoking
- Concomitant diabetes
- Ill-fitting dentures, resulting in mechanical injury
- Renal impairment and advanced age may be associated with increased MRONJ severity
- Rheumatoid arthritis (RA):
  1. Compain et al (2018) found that BRONJ seems to occur earlier in patients with RA than with osteoporosis (46.8 vs. 63.6 mo); likely due to age at initiation of BP, cumulative dose, immunosuppression, chronic vasculitis, dental health status, and concomitant disease-modifying treatments.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Exposed areas of necrotic bone in the mandible or maxilla, with 65% of cases involving the mandible. Multifocal or bilateral involvement is possible but uncommon. Pathologic fracture of the jaw may occur.
- Pain in the maxillofacial region, although one third of lesions may be painless.
- Paresthesia of the chin is an early sign.
- Tooth mobility or spontaneous tooth loss.
- Mucosal swelling, erythema, ulceration, altered sensation.
- Infection.
- BRONJ due to IV BPs may produce larger and more frequent buccolingual cortical bone perforations than oral BPs.
- DRONJ may produce large sequestrum and periosteal reaction.

ETIOLOGY

Exposure to BPs as well as other antiresorptive and antiangiogenic agents

DIAGNOSIS

The AAOMS considers a diagnosis of MRONJ if the following three characteristics are present:

1. Current or previous treatment with a BP, denosumab, or antiangiogenic agent
2. Exposed bone or bone that can be probed through intraoral or extraoral fistulae in the maxillofacial region persisting for more than 8 wk
3. No history of radiation therapy to the maxillofacial region or evident metastatic disease to the jaw

DIFFERENTIAL DIAGNOSIS

- Suppurative osteomyelitis of the jaw (SOJ)
- Osteoradionecrosis of the jaw (ORNJ)
- Alveolar osteitis, gingivitis, sinusitis, fibro-osseous lesion, sarcoma, sclerosing osteomyelitis, periodontitis, dental caries, and temporomandibular joint disorders

WORKUP

- Treatment history, including medications and radiation therapy
- Past medical history, including osteoporosis and malignancy

LABORATORY TESTS

A validated diagnostic test is not available to identify patients at an increased risk of BRONJ. Tissue biopsy should only be performed if metastatic disease is strongly suspected and its detection would change the management of BRONJ. Histopathology of BRONJ shows empty osteocytic lacunae, empty Haversian and Volkmann canals, an absence of inflammatory cells or blood vessels in the marrow space, and absence of extracellular collagenase.

IMAGING STUDIES

Panoramic and periapical radiographs

Rx TREATMENT

Goals of treatment for MRONJ include:
- Control or reduce pain.
- Control secondary infection.
- Minimize progression or occurrence of bone necrosis, as well as extension of lesion(s).

NONPHARMACOLOGIC THERAPY

The AAOMS recommends the following surgical strategies based on MRONJ staging:
- Stage 0 (no clinical evidence of necrotic bone, nonexposed bone variant): No surgery
- Stage 1 (exposed and necrotic bone, or fistulae that probe to bone, asymptomatic, no infection): No surgery
- Stage 2 (exposed and necrotic bone, or fistulae that probe to bone, with pain or infection): Superficial debridement
- Stage 3 (exposed and necrotic bone with pain, infection, *and* one of the following features: necrosis extending beyond alveolar bone, pathologic fracture, extraoral fistula, oral antral or nasal communication, osteolysis extending to mandible of sinus floor): Surgical debridement or resection for palliation of infection and pain

Literature suggests that success rates with surgical management are higher and less variable than with conservative management. The AAOMS recommends surgery for patients with stage 3 MRONJ. However, a surgical margin with viable bone can be difficult to obtain. The entire jawbone likely has been exposed to accumulation of the drug (especially BPs), and therefore successful eradication of necrotic bone is often not possible. Those areas of necrosis that consistently irritate soft tissues should undergo debridement as necessary because dead tissue will interfere with wound healing and will be prone to infection. Another consideration is that some patients may not be surgical candidates if their overall health is poor and/or if chemotherapy is incomplete.

Limited evidence supports the use of hyperbaric oxygen as adjunct to surgery and antibiotics to slow progression and improve pain. Small case reports have documented the use of platelet-rich plasma, low-level laser irradiation, parathyroid hormone, and bone morphogenic protein; however, the efficacy of these methods has not been established through controlled studies.

With regards to surgery for stages 2 and 3, Kagami et al (2015) found that curettage under local anesthesia had a higher risk of relapse than sequestrectomy, saucerization, or mandibulectomy. Shibahara et al (2018) observed that the majority of patients with stage 2 BRONJ who underwent surgery (N = 936) achieved remission (46.3%) or improvement in BRONJ (30.6%). Stage 2 surgery may also be reasonable for older patients or those with limited life expectancy, rather than lengthy debridement that may significantly decrease quality of life.

ACUTE GENERAL Rx

Both chlorhexidine mouth rinse and antibiotics for 1 to 3 wk have been found useful for stage reduction. Most microbes are sensitive to penicillin antibiotics.
- Chlorhexidine 0.12% antibacterial mouth rinse daily for stages 1 to 3
- Oral antibiotics for symptomatic stage 2 and oral or IV antibiotics for stage 3
- Analgesics for stages 2 or 3

CHRONIC Rx

- Determine whether discontinuation of antiresorptive agent is appropriate. A multicenter retrospective chart review by Hayashida et al (2019) evaluated 427 cases in patients with osteoporosis or malignancy. Discontinuation of antiresorptive therapy significantly increased cure rate in those with osteoporosis who underwent nonsurgical treatment and did not impact any patients who underwent surgical treatment.
  1. Evaluate potential benefit of continuing antiresorptive agent, such as relief of bone pain in malignancy or prevention of fractures with high morbidity and mortality.
  2. BPs have a prolonged half-life, so return to normal osteoclast function and bone turnover may be too gradual.
  3. Consider other risks of antiresorptive agents, such as atypical femoral fractures.
- If discontinuing antiresorptive agents, consider alternative treatments for osteoporosis or bone pain.
- Anecdotal case reports exist for using teriparatide (unless the patient has bone metastases or is at risk for osteosarcoma) or pentoxifylline plus tocopherol to heal BRONJ.
- Patients with malignancy and any stage of MRONJ: Dental specialist should re-evaluate lesions every 8 wk and communicate condition to oncologist.

DISPOSITION

A retrospective cohort study in Japan by Shibahara et al (2018) showed that lack of risk factors for BRONJ, performing surgical removal/reduction/resection in stage 2 BRONJ, a completely closed wound, and discontinuing BPs were all associated with a positive prognosis.
- Patients with involvement of the maxilla appear to have a greater likelihood of repeat surgery.
- Patients taking oral rather than IV BPs may have less severe complications and may have a better response.
- Treatment with antibiotics and chlorhexidine mouth rinse, withdrawal of BPs, and surgical removal of loose sequestra may possibly reduce pain and lesions of osteonecrosis.

Concomitant diabetes, lower serum albumin, malignancy as indication for antiresorptive agent, and nonsurgical treatment of MRONJ were associated with worse outcomes, including poor healing rate, in the chart review by Hayashida et al (2019).

REFERRAL

Oral and maxillofacial surgeon

PEARLS & CONSIDERATIONS

COMMENTS

- Patients may be asymptomatic for wk to yrs before BRONJ is apparent.
- Radiographic changes may not be observed until significant disease has developed.
- Tooth extraction may be difficult to avoid in patients at high risk of BRONJ if an underlying bacterial infection is present.
- Patients with malignancy are at highest risk because the dosages of BPs are much higher than for osteoporosis.
- Use of BPs in pediatric patients has increased without identified cases of BRONJ to date. Further evaluation of long-term use of BPs in these patients is warranted.

PREVENTION

- Regular dental hygiene and routine (every 3 mo for patients with malignancy) dental examinations.
  1. Results from Coello-Suanzes et al (2018) for 255 patients with malignancy showed that patients who received dental procedures prior to initiation of zoledronic acid had a statistically significant lower incidence of BRONJ (7.3% vs. 36.5%).
- Appropriate fitting of dentures with periodic mucosal examination.
- Assessment of patients for other risk factors of MRONJ.
- Completion of any anticipated dental procedures before beginning antiresorptive therapy.
- Asymptomatic patients receiving IV BPs: Limit dental surgery to removal of nonrestorable teeth and avoid dental implants in patients who also have cancer.
- The 2014 AAOMS position paper supports a 2-mo drug holiday before oral surgery for patients who have received BPs for greater than 4 yr or for patients exposed to less than 4 yr of BPs and taking concomitant corticosteroids or antiangiogenics. Allow osseous healing to complete before restarting BPs. A 2017 retrospective study did not find a difference in ONJ incidence due to preextraction drug holidays of 2 or 3 mo. In terms of long-term BP drug holidays:
  1. Results from the FLEX trial suggest that women with postmenopausal osteoporosis who have taken alendronate for 5 yr and are at low risk of vertebral fractures may discontinue the drug for up to 5 yr.
  2. Results from the HORIZON-PFT extension trial suggest that women with postmenopausal osteoporosis who have taken IV zoledronic acid for 3 yr and are at low risk of vertebral fractures may discontinue for up to 3 yr.
- Careful monitoring of patients after dentoalveolar surgery and delayed initiation of BPs by at least 2 to 3 wk to allow for osseous healing.
- Evidence suggests a threefold reduction in the incidence of ONJ when preventive measures are practiced.

PATIENT & FAMILY EDUCATION

- All health care providers should be aware of past and current use of antiresorptive agents.
- Contact a health care provider if any of the following are observed:
  1. Presence of exposed bone in the maxillofacial area
  2. Persisting pain in the maxillofacial area

3. Signs of infection such as fever, pus, and swelling

- Practice good dental hygiene and keep regular dental appointments.
- Patients needing assistance with access to dental care may contact the AAOMS, the Centers for Medicare & Medicaid Services, the United Way, nearby dental schools, or their local health department.

Meigs Syndrome

BASIC INFORMATION

DEFINITIONS

- **Classic Meigs syndrome:** A triad characterized by the presence of ascites and pleural effusion (usually right-sided) in association with a benign fibroma or fibroma-like ovarian tumor (thecoma, granulosa cell tumor, or Brenner tumor).
- **Nonclassic Meigs syndrome:** Characterized by ascites and pleural effusion in conjunction with a benign ovarian, fallopian tube, or broad ligament tumor that is not included in the definition of classic Meigs syndrome.
- **Pseudo-Meigs syndrome:** Characterized by both ascites and pleural effusion but caused by a pelvic or abdominal tumor, either benign or malignant, not included in either classic Meigs or nonclassic Meigs syndrome, such as leiomyomas, struma ovarii, mucinous cystadenoma, teratoma, and malignancies that are metastatic to the ovary (particularly colorectal cancer).
- **Pseudo-pseudo Meigs (Tjalma) syndrome:** Characterized by the triad of ascites, pleural effusion, and an elevated CA-125 (Cancer antigen 125) in a patient with systemic lupus erythematosus.

ICD-10CM CODES

C56.9	Malignant neoplasm of unspecified ovary
D27.9	Benign neoplasm of unspecified ovary
D28.2	Benign neoplasm of uterine tubes and ligaments
D28.7	Benign neoplasm of other specified female genital organs
J91.8	Pleural effusion in other conditions classified elsewhere
R18.0	Malignant ascites
R18.8	Other ascites

EPIDEMIOLOGY & DEMOGRAPHICS

- Occurs in 1% to 2% of ovarian fibromas (associated with approximately 0.004% of ovarian tumors)
- <1% progress to malignancy
- Incidence begins to increase in the 30s. Most frequently encountered in postmenopausal women (average age 50 yr)

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Abdominal bloating/increased girth
- Intermittent pelvic pain (intermittent torsion)
- Weight gain or loss
- Pelvic mass on bimanual examination
- Acute pelvic/abdominal tenderness
- Fluid wave
- Shifting dullness
- "Puddle sign" (physical exam maneuver)
- Hyperresonance or flatness to chest percussion, absence of tactile and vocal fremitus
- Absent or loud bronchial breath sounds, rales, mediastinal displacement, tracheal shift

ETIOLOGY

- Unknown
- Hypothesized to be due to "edematous" fibromas (or other benign ovarian solid tumors) in excess of 10 cm that may stimulate the peritoneal lining to produce peritoneal fluid
- Alternative theory of large fibroma with narrow stalk has inadequate lymphatic drainage; when coupled with intermittent torsion, results in backflow transudation into the peritoneal cavity
- Pleural effusion likely arises from passage of accumulated peritoneal ascites to the right pleural cavity via lymphatics (overloaded thoracic duct) or abdominal pleural commutation (i.e., foramen of Bochdalek)
  1. Fluid accumulation may be due to substances like vascular endothelial growth factor (VEGF) that raise capillary permeability

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Ovarian malignancy
- Various gynecologic disorders:
  1. Uterus: Endometrial tumor, sarcoma, leiomyoma ("pseudo-Meigs syndrome")
  2. Fallopian tube: Hydrosalpinx, granulomatous salpingitis, fallopian tube malignancy
  3. Ovary: Benign, serous, mucinous, endometrioid, clear cell, Brenner tumor, granulosa, stromal, dysgerminoma, fibroma, metastatic tumor
- Nongynecologic causes of abdominopelvic ascites:
  1. Portal vein obstruction
  2. Inferior vena cava obstruction
  3. Hypoproteinemia
  4. Thoracic duct obstruction
  5. Tuberculosis
  6. Amyloidosis
  7. Pancreatitis
  8. Gastrointestinal/genitourinary neoplasm
  9. Ovarian hyperstimulation
  10. Pleural effusion
  11. Congestive heart failure
  12. Collagen-vascular disease
  13. Cirrhosis

WORKUP

- Clinical condition characterized by ovarian mass, ascites, and predominantly right-sided pleural effusion
- History of early satiety, weight loss with increased abdominal girth, bloating, intermittent abdominal pain, dyspnea, and nonproductive cough

LABORATORY TESTS

- Complete blood count to rule out inflammatory process
- Tumor markers (CA-125, human chorionic gonadotropin, alpha-fetoprotein, carcinoembryonic antigen, lactic dehydrogenase) to evaluate gynecologic malignancy
- Chemical and liver function testing profile to evaluate metabolic or hepatic involvement
- Arterial blood gases if respiratory compromise

IMAGING STUDIES

- Pelvic sonography (color-flow Doppler evaluation of adnexal mass) initially to evaluate pelvic pathology (CT scan or MRI to further delineate neoplastic lesions)
- Chest x-ray to confirm pleural effusion

Procedures:

- Paracentesis/thoracentesis will usually show a transudate

TREATMENT

NONPHARMACOLOGIC THERAPY

- Informed consent and proper preparation of patient for possible staging laparotomy (total abdominal hysterectomy and bilateral salpingo-oophorectomy, possible omentectomy, possible bowel resection, and possible pelvic/periaortic lymphadenectomy)
  1. Can consider unilateral salpingo-oophorectomy in reproductive-age women, whereas total hysterectomy is preferred in postmenopausal women
- Bowel prep if considering pelvic malignancy

ACUTE GENERAL TREATMENT

Depending on clinical presentation, size of pelvic mass, amount of ascites, and pleural effusion:

- If pelvic mass <10 cm with minimal ascites/pleural effusion: Consider diagnostic laparoscopy (possible exploratory laparotomy) and salpingo-oophorectomy with removal of ovarian fibroma (tumor).
- If pelvic mass >10 cm with moderate/large amount ascites/pleural effusion: Consider pleurocentesis if respiratory compromise (cytology: acid fast bacillus) and exploratory laparotomy with salpingo-oophorectomy and removal of ovarian tumor.
- Treat pelvic malignancy, gastrointestinal, or genitourinary tumor as indicated.

CHRONIC TREATMENT

- Resolution of ascites and pleural effusion after removal of ovarian tumor
- Routine gynecologic follow-up for benign ovarian tumor

DISPOSITION

Dramatic resolution of ascites and effusion within wks of resection of pelvic mass is seen. Excellent progress and complete survival are expected. Recurrence rate is low.

REFERRAL

- To gynecologic oncologist for evaluation and treatment, especially if malignancy considered or encountered
- To pulmonologist for management of pleural effusion

BASIC INFORMATION

DEFINITION

Melanoma is a skin neoplasm arising from the malignant degeneration of melanocytes. It is classically subdivided in four types (Table 1):

1. Superficial spreading melanoma (70%)
2. Nodular melanoma (15%)
3. Lentigo maligna melanoma (4% to 10%) (Fig. E1)
4. Acral lentiginous melanoma (5% to 10%)

SYNONYMS

Malignant melanoma
Cutaneous malignant melanoma

ICD-10CM CODES

C43.30	Malignant melanoma of unspecified part of face
C43.31	Malignant melanoma of nose
C43.4	Malignant melanoma of scalp and neck
C43.51	Malignant melanoma of anal skin
C43.52	Malignant melanoma of skin of breast
C43.59	Malignant melanoma of other part of trunk
C43.8	Malignant melanoma of overlapping sites of skin
C43.9	Malignant melanoma of skin, unspecified
D03.8	Melanoma in situ of other sites
D03.9	Melanoma in situ, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

- In 2019, there were an estimated 96,480 new cases and 7,230 deaths in the U.S.; the estimated lifetime risk of development of melanoma is 1 in 50.
- Melanoma is much more common in whites (17.2 per 100,000 white men) than in African Americans (1 per 100,000 African American men). Increased risk of developing melanomas is found in patients with fair skin, red hair, light eyes, abundance of freckles, atypical moles or large amount of moles (>50). A personal history of any skin cancer or a family history of melanoma also increases the risk.
- Melanoma is the leading cause of death from skin cancer. Although it represents <10% of all skin-cancers, it accounts for at least 70% of deaths related to skin cancer.
- The median age at diagnosis is 53 yr.
- Superficial spreading melanoma occurs most often in young adults on sun-exposed areas.
- Acral lentiginous melanoma is most often found in Asian Americans and African Americans and is unrelated to sun exposure.
- Eight percent to 10% of melanomas arise in people with a family history of the disease.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Variable depending on the subtype of melanoma:

- Superficial spreading melanoma is most often found on the lower legs, arms, and upper back. It may have a combination of many colors or may be uniformly brown or black.
- Nodular melanoma can be found anywhere on the body, but it most frequently occurs on the trunk on sun-exposed areas. It has a dark-brown or red-brown appearance and can be dome shaped (Fig. E2) or pedunculated. Lesions are frequently misdiagnosed because they may resemble a blood blister or hemangioma and may also be amelanotic.
- Lentigo maligna melanoma is generally found in older adults in areas continually exposed to the sun and frequently arising from lentigo maligna (Hutchinson freckle) or melanoma in situ. It might have a complex pattern and variable shape; color is more uniform than in superficial spreading melanoma.
- Acral lentiginous melanoma frequently occurs on soles, subungual mucous membranes, and palms (sole of the foot is the most prevalent site). Unlike other types of melanoma, it has a similar incidence in all ethnic groups.
- The warning signs that the lesion may be a melanoma can be summarized with the ABCDE mnemonic (Table 2):
  - **A:** Asymmetry (e.g., lesion is bisected and halves are not identical)
  - **B:** Border irregularity (uneven, ragged border) (Fig. E3)
  - **C:** Color variegation (presence of various shades of pigmentation)
  - **D:** Diameter enlargement (>6 mm)
  - **E:** Evolving (mole changing in size, shape, or color, or mole that differs visibly from surrounding moles ["ugly duckling" sign])

ETIOLOGY

- Ultraviolet light is the most important cause of malignant melanoma.
- There is a modest increase in melanoma risk in patients with small nondysplastic nevi and a much greater risk in those with dysplastic lesions.
- The *CDKN2A* gene, residing at the 9p21 locus, is often deleted in patients with familial melanoma.
- A mutated signal transduction molecule, v-raf murine sarcoma viral oncogene homolog B *(BRAF),* has been identified in 40% to 60% of patients with melanoma.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Dysplastic nevi
- Solar lentigo
- Vascular lesions
- Blue nevus
- Basal cell carcinoma
- Seborrheic keratosis

WORKUP

- Dermoscopy (use of an instrument that shines polarized light on skin surfaces and magnifies skin lesions) can increase the accuracy in diagnosing melanoma by 10% to 27%.

TABLE 1 Four Histologic Subtypes of Cutaneous Melanoma

SUPERFICIAL SPREADING MELANOMA

- Incidence: Accounts for 70% of all melanomas, tends to occur in younger patients (median age, 50)
- Anatomic site: Any; predominantly trunk and extremities, anatomic sites associated with intermittent sun exposure
- Clinical appearance: Change in the appearance of a large mole, asymmetry, irregular border, variegated color (brown, black, pink, white, gray, and blue), often arising in a precursor mole
- Can be associated with mutation in *BRAF*

LENTIGO MALIGNA MELANOMA

- Incidence: Accounts for 4% to 10% of all melanoma; tends to occur more commonly in older patients
- Anatomic site: Areas with chronic exposure to the sun, head and neck regions, and distal extremities
- Clinical appearance: Macular (flat) lesion; arising in a lentigo maligna, which often appears as a flat, light brown skin lesion
- Can be associated with mutation in *KIT*

NODULAR MELANOMA

- Incidence: Accounts for 15% of melanomas
- Anatomic site: Any
- Clinical appearance: Rapidly enlarging, elevated, or polypoid lesion; often arising in normal skin; often blue, black, or pink and can be amelanotic

ACRAL LENTIGINOUS MELANOMA

- Incidence: 5%-10%
- Anatomic site: Most commonly on the palms or soles or subungual (under the nail bed)
- Clinical appearance: Darkly pigmented, flat to nodular lesion, highly irregular borders
- Can be associated with mutation in *KIT*

From Niederhuber JE: *Abeloff's clinical oncology,* ed 6, Philadelphia, 2020, Elsevier.

TABLE 2 Clinical Features (ABCDE Signs) of Malignant Melanoma

	Clinical Feature	Comment
A	Asymmetry	The two halves of the lesion are not alike
B	Border irregularity	Borders notched, scalloped, irregular
C	Color changes	Especially blue, red, black, white
D	Diameter >6 mm	Size of a pencil eraser; not applicable to congenital nevi, which are often >6 mm early in their evolution
E	Enlargement	Evolutionary change in the lesion

From Paller AS, Mancini *AJ: Hurwitz clinical pediatric dermatology, a textbook of skin disorders of childhood and adolescence,* ed 5, Philadelphia, 2016, Elsevier.

- Any suspicious lesion (Fig. E4) should be biopsied. Perform excisional biopsy with elliptical excision that includes 1 to 2 mm of normal skin surrounding the lesion and extends to the subcutaneous tissue; incisional punch biopsy is sometimes necessary in surgically sensitive areas (e.g., digits, nose). It is essential that the size of the specimen be adequate to determine the histologic depth of penetration, which is known as the Breslow depth.
- Sentinel lymph node excision (SLNE) is the most important staging and potentially therapeutic procedure for patients with melanoma. It should be considered in patients with intermediate (1 to 4 mm) melanomas or high-risk skin tumors to obtain information regarding a patient's subclinical lymph node status with minimal morbidity. The National Comprehensive Cancer Network (NCCN) recommends that SLNE be discussed with and offered to patients classified as stage IB or II, and should be considered for patients with stage IA melanoma and "adverse" features that might portend a higher risk of sentinel node involvement (e.g., Clark level IV or V, tumor thickness of 0.75 mm or more, lymphovascular invasion, positive deep margins). SLNE involves the use of radiologic lymphoscintigraphy to map lymphatic drainage from the site of the primary melanoma to the first sentinel lymph node in the region. When properly performed, if the sentinel node is negative the remaining lymph nodes in the region will not have metastases in more than 98% of cases. If the sentinel nodes are negative, no additional regional surgery is recommended. The staging of intermediate thickness (1.2 to 3.5 mm) primary melanomas, according to the results of sentinel node biopsy, provides important prognostic information and identifies patients with nodal metastases whose survival can be prolonged by immediate lymphadenectomy.
- The staging system for melanoma adapted by the American Joint Committee on Cancer (AJCC) can be found in Table 3.

LABORATORY TESTS

The pathology report should indicate the following:

- Tumor thickness (Breslow microstage).
- Tumor depth: The depth of invasion is the most important histologic prognostic parameter in evaluating the primary tumor.
- Mitotic rate: Tabulated as mitoses per square millimeter in the dermal part of the tumor in which most mitoses are identified.
- Radial growth rates versus vertical growth rate: Radial growth phase describes the growth of melanoma within the epidermis and along the dermal-epidermal junction.
- Tumor infiltrating lymphocytes have a strong predictive value in vertical growth phase melanomas and are defined as brisk, nonbrisk, or absent.
- Histologic regression: Characterized by the absence of melanoma in the epidermis and dermis flanked on one or both sides by melanoma.
- Reverse-transcription polymerase chain reaction assay for tyrosine messenger RNA is a useful marker for the presence of melanoma cells. It is performed on sentinel lymph node biopsy and is useful for detection of submicroscopic metastases.

Rx TREATMENT

- Initial excision of the melanoma
- Re-excision of the involved area after histologic diagnosis:
  1. The margins of re-excision depend on the Breslow depth. For melanoma in situ with Breslow depth ≤2.0 mm, recommended surgical margin is 1 cm. If Breslow depth is ≤2.0 mm, margin should be 2 cm. For melanoma in situ, margin should be 5 mm.
  2. Low-risk or intermediate-risk tumors require excision of 1 to 3 cm.
  3. Melanomas of moderate thickness (0.9 to 2.0 mm) can be excised safely with 2-cm margins.
  4. A 1-cm margin of excision for melanoma with a poor prognosis (as defined by a tumor thickness ≥2 mm) is associated with a significantly greater risk of regional recurrence than is a 3-cm margin, but with a similar overall survival rate. Randomized clinical trials have also shown that radical surgery with 2-cm excision margins did not differ from that with 4-cm margins for survival in patients with cutaneous melanoma >2 mm thick.
- Lymph node dissection: Recommended in all patients with enlarged lymph nodes. Lymph node evaluation is important in patients with melanoma 1 mm in depth because it determines the overall prognosis and need for therapeutic lymph node dissection or adjuvant treatment.
  1. Elective lymph node dissection remains controversial.
  2. It is indicated with positive sentinel node. It may be considered in those with a primary melanoma between 1 and 4 mm thick (especially in patients >60 yr).
- Adjuvant therapy:
  1. Interferon alfa-2b and Peginterferon alfa-2b have been previously used for the adjuvant treatment resected stage III melanoma despite modest benefits.
  2. Ipilimumab, an antibody that blocks cytotoxic T-lymphocyte–associated antigen 4 (CTLA-4), improves survival in stage III high-risk resected melanoma but is associated with significant immune adverse events.
  3. Immune checkpoint PD-1 (programmed death receptor-1) antibodies nivolumab and pembrolizumab have demonstrated superiority to ipilimumab in patients with resected high-risk stage III melanoma; currently only nivolumab is approved in this setting.
  4. The combination regimen of BRAF inhibitor and MEK inhibitor (dabrafenib plus trametinib) has shown improved relapse-free survival in cases of resected BRAF V600-mutant stage III melanoma and is another option for these patients.
- Advanced disease:
  1. The use of immune checkpoint inhibitors has improved overall survival in patients with previously treated or untreated metastatic melanoma irrespective of BRAF mutation status. Monotherapy with the PD-1 inhibitors nivolumab or pembrolizumab has been approved for the treatment of metastatic melanoma in treatment-naïve patients and also in cases of progression after initial therapy with ipilimumab.
  2. Combination immunotherapy with the use of nivolumab and ipilimumab in previously untreated patients with unresectable or metastatic melanoma has been shown to be more effective than ipilimumab alone as first-line treatment in high-risk patients though severe immune toxicity is seen in the majority of patients.
  3. In patients who carry the V600E *BRAF* mutation, the combination of oral BRAF inhibitors and oral MEK inhibitors improves overall survival in patients with previously untreated melanoma. Three such combination regimens (vemurafenib plus cobimetinib; dabrafenib plus trametinib; and encorafenib plus binimetinib) are approved by the FDA for use in this setting. Targeted therapy is useful in patients with rapidly growing melanoma with *BRAF* mutations, but resistance appears in almost all patients, and median progression-free survival is 15 to 18 mo. Interestingly, the

TABLE 3 The TNM Classification for Melanoma Adapted by the American Joint Committee on Cancer (AJCC, 8th edition)

T classification	Thickness	Ulceration status/mitoses
T_{is} (in situ)	n/a	n/a
T_1	<1.0 mm	Unknown or unspecified
T_{1a}	<0.8 mm	Without ulceration

N_{3a}	Four or more clinically occult (sentinel biopsy detected)	No
N_{3b}	Four or more, at least one of which was clinically detected, or the presence of any number of matted nodes	No
N_{3c}	Two or more clinically occult or clinically detected and/or presence of any number of matted nodes	Yes
M category	**Anatomic site**	**LDH level**
M_0	No distant metastases	n/a
M_1	Evidence of distant metastases	
M_{1a}	Distant metastasis to skin, soft tissue including muscle, and/or nonregional lymph node	M_{1a}(0): Normal M_{1a}(1): Elevated
M_{1b}	Distant metastasis to lung with or without M_{1a} sites of disease	M_{1b}(0): Normal M_{1b}(1): Elevated
M_{1c}	Distant metastasis to non-CNS visceral sites with or without M_{1a} or M_{1b} sites of disease	M_{1c}(0): Normal M_{1c}(1): Elevated
M_{1d}	Distant metastasis to CNS with or without M_{1a}, M_{1b}, or M_{1c} sites of disease	M_{1d}(0): Normal M_{1d}(1): Elevated

CNS, Central nervous system; *LDH,* lactic dehydrogenase; *TNM,* tumor, nodes, metastases.

majority of patients with melanoma CNS metastases in this setting have similar response rates in the CNS as systemically.

4. The combination of atezolizumab (PD-L1 checkpoint inhibitor), cobimetinib (MEK inhibitor), and vemurafenib (BRAF inhibitor) has been shown to improve progression-free survival compared with placebo in patients with *BRAF* mutated advanced melanoma and is likely to be another option in this setting.

- Patients with a history of melanoma should be followed up with skin examinations every 6 mo or sooner if patient detects any new lesions; the assessments usually consist of medical history, physical examination, laboratory values, and chest radiograph.

DISPOSITION

- Prognosis varies with the stage of the melanoma. The 5-yr survival related to thickness is as follows: <0.76 mm, 99% survival; 0.6 to 1.49 mm, 85%; 1.5 to 2.49 mm, 84%; 2.5 to 3.9 mm, 70%; >4 mm, 44%.
- The 5-yr survival in patients with distant metastasis was historically <10% but is improving with current therapeutic options and is now >20%.
- Treatment of advanced disease consists (in addition to surgical excision and lymph node dissection) of chemotherapy, immunotherapy, and radiation therapy. Nivolumab combined with ipilimumab has shown clinically meaningful activity in melanoma metastatic to the brain (see Tawbi HA et al in Suggested Readings).

Ménière Disease PTG

BASIC INFORMATION

DEFINITION

Ménière disease is a syndrome characterized by recurrent vertigo with fluctuating hearing loss, tinnitus, and fullness in the ear.

SYNONYMS

Endolymphatic hydrops
Lermoyez syndrome
Idiopathic endolymphatic hydrops

ICD-10CM CODES

H81.01 Ménière disease, right ear
H81.02 Ménière disease, left ear
H81.03 Ménière disease, bilateral
H81.09 Ménière disease, unspecified ear

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): Approximately 190/100,000 persons
PREDOMINANT SEX: Female:male ratio of 1.3:1
PEAK INCIDENCE: Fourth to sixth decade of life

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Hearing may be unilaterally decreased.
- Pallor, sweating, and nausea may occur during a severe attack.
- Usually the patient develops a sensation of fullness and pressure along with decreased hearing and tinnitus in a single ear.
- The patient typically experiences severe vertigo, which peaks within minutes, then slowly subsides over hours.
- May see spontaneous nystagmus on examination.
- Persistent sense of disequilibrium for days is typical after an acute episode.
- May have vestibulopathy demonstrable with a positive head thrust test.

ETIOLOGY

- Unknown; viral, autoimmune, and genetic causes have been suggested.
- Endolymphatic hydrops is the postmortem histologic hallmark. Endolymphatic hydrops may create cytochemical changes that disturb endolymphatic fluid homeostasis, leading to spiral ganglion cell death.

DIAGNOSIS

Proposed guidelines by the American Academy of Otolaryngology-Head and Neck Surgery (AAO-HNS) for diagnosis of Ménière disease:

DIFFERENTIAL DIAGNOSIS

- Acoustic neuroma
- Migrainous vertigo
- Multiple sclerosis
- Autoimmune inner ear syndrome
- Otitis media
- Vertebrobasilar disease
- Labyrinthitis

WORKUP

- Diagnosis is primarily made by history, although further diagnostic tests may help support the diagnosis. Guidelines to define Ménière disease are described in Table 1.
- Audiogram may show sensorineural hearing loss with lower frequencies primarily affected. Hearing loss may recover either partially or completely after an attack. Recurrent attacks may lead to a persistent and progressive sensorineural hearing loss.
- Electronystagmography may show peripheral vestibular deficit.
- Both vestibular-evoked myogenic potential (VEMP) studies and electrocochleography (ECoG) have low sensitivity and specificity for Ménière disease and are not clinically useful.

LABORATORY TESTS

No laboratory serologic test is specific for Ménière disease. A thyroid panel, glucose, hemoglobin A1C, antinuclear antibodies, urinalysis, chemistry panel, rapid plasma reagin, Lyme disease antibodies, and allergy testing can be ordered to screen for other disorders such as thyroid or autoimmune diseases, diabetes, otorenal syndrome, syphilis, Lyme disease, and allergy-mediated Ménière disease.

IMAGING STUDIES

- MRI to rule out acoustic neuroma or other retrocochlear lesion, especially if cerebellar or CNS dysfunction is present.
- Recent efforts have shown a role for MRI with intratympanic gadolinium.

TREATMENT

NONPHARMACOLOGIC THERAPY

Limit activity during attacks.

ACUTE GENERAL Rx

- Prochlorperazine 5 to 10 mg PO q6h or 25 mg PO bid
- Promethazine 12.5 to 25 mg PO q4 to 6h
- Diazepam 5 to 10 mg IV/PO for acute attack
- Meclizine 25 mg q6h
- Scopolamine patch

CHRONIC Rx

- Diuretics such as furosemide, hydrochlorothiazide, or acetazolamide.
- Lifestyle modification recommendations include salt restriction and avoidance of caffeine.
- For refractory cases, intratympanic gentamicin injections to the affected ear; endolymphatic sac surgery.

DISPOSITION

- Patients are usually followed by an otoneurologist or ENT specialist.
- Usual course of disease consists of alternating attacks and remissions.
- Majority of patients can be managed medically. Of all patients, 10% to 30% will undergo surgical intervention for persistent incapacitating vertigo.

REFERRAL

To an otolaryngologist for surgical intervention if attacks persist despite medical therapy

AUTHORS: **Katherine Kostroun, MD, Joseph S. Kass, MD, JD, FAAN,** and **Sharon S. Hartman Polensek, MD, PhD**

TABLE 1 Guidelines to Define Ménière Disease

Definition	Symptoms
Certain Ménière disease	Histopathologic confirmation
Definite Ménière disease	≥2 definitive spontaneous episodes of vertigo 20 min to 12 hr Audiometrically documented low- to medium-frequency sensorineural hearing loss in one ear, defining the affected ear on at least one occasion before, during, or after one of the episodes of vertigo Fluctuating aural symptoms (hearing, tinnitus, or fullness) in the affected ear Not better accounted for by another vestibular diagnosis
Probable Ménière disease	One definite episode of vertigo Audiometrically documented hearing loss on at least one occasion Tinnitus or aural fullness in the treated ear Other causes excluded
Possible Ménière disease	Episodic vertigo without documented hearing loss, or sensorineural hearing loss (SNHL) fluctuating or fixed, with disequilibrium but nonepisodic Other causes excluded

BASIC INFORMATION

DEFINITION

Meningiomas are generally slow-growing tumors arising from arachnoid cells of the arachnoid villi; 90% are benign.

ICD-10CM CODE

D32.0 Benign neoplasm of cerebral meninges

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: 7.92/100,000 persons/yr, but increases with age. Most common primary type of central nervous system tumor, and most common nonmalignant primary central nervous system tumor.

PREDOMINANT SEX AND AGE: Female:male ratio of almost 3:1 (in ages 35 to 54) in the brain and up to 6:1 in the spinal cord; 1:1 in childhood

PEAK INCIDENCE: Males: Sixth decade, females: Seventh decade, incidence increases with age, dramatic increase in incidence after age 65; rare in childhood

RISK FACTORS: Ionizing radiation results in increased incidence and a shorter latency period. Neurofibromatosis type 2 (NF2) is an autosomal dominant genetic disorder that predisposes to multiple intracranial tumors. Approximately half of all individuals with NF2 have meningiomas, most of which are intracranial. Studies have suggested a link between hormonal factors and development of meningioma, specifically estrogen exposure. Multiple prospective cohorts studies have also found an association between higher body mass index and meningioma, possibly relating to increased levels of circulating estrogen through increased adipose tissue. At present, there is no conclusive evidence to support a causal relationship with cell phone usage and subsequent development of meningioma.

GENETICS: Meningiomas may be isolated or found in association with other genetic diseases, such as NF2 and familial meningioma. Other genetic conditions associated with increased incidence of meningioma include BAP1 tumor predisposition syndrome, Rubinstein-Taybi syndrome, multiple endocrine neoplasia, type 1, Gorlin syndrome, Cowden syndrome 1, Werner syndrome, and familial meningiomatosis. Approximately half of meningiomas have allelic losses involving the *NF2* and *DAL-1* genes. Allelic losses of chromosomes 1p, 2p, 6q, 9q, 10q, 14q, 17p, and 18q may be associated with histologic progression. Genome-wide association studies (GWAS) have discovered two genomic variants associated with increased meningioma risk in genes for *MLLT10* and possibly *RIC8A*. Further, GWAS analysis also demonstrates an association between longer telomere length and increased risk of meningiomas.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Neurologic symptoms vary with location and size (see Table 1); meningiomas can arise from the dura at any site, although they most commonly occur within the skull and at sites of dural reflection (i.e., the cerebral convexities and the falx). Other less common locations include the sphenoid wing, olfactory groove, and optic nerve sheath.
- The presence of focal symptoms such as vision loss, hearing loss, or mental status change depend on the site of origin and the time course of growth.
- Most common presentation is with a focal or generalized seizure or gradually worsening neurologic deficit. Seizures are present preoperatively in 30% to 40%.
- Typically are slow growing and asymptomatic; many meningiomas are asymptomatic and/or discovered incidentally on a neuroimaging study or at autopsy.

ETIOLOGY

- Meningiomas are thought to arise from a multistep progression of genetic changes.
- Mutations of the *NF2* gene on chromosome 22 are found in patients with neurofibromatosis type 2 and >50% of sporadic meningiomas. This gene is thought to act as a tumor suppressor gene; the protein product, merlin, is also involved in cytoskeletal organization.
- *DAL-1*, located on chromosome 18p, is another tumor suppressor gene that has been identified in a subset of the approximately 40% of sporadic meningiomas with neither the *NF2* gene mutations nor allelic loss of chromosome 22q.
- Cranial radiation may be responsible for some cases following an appropriate latency period from 10 to 20 yr. Meningiomas that result from radiation are generally more aggressive.
- The link with steroid hormones and their receptors is suggested by the increase in growth rate and/or development of meningiomas during pregnancy, increased incidence in women who use postmenopausal hormones, and in association with breast carcinomas.

TABLE 1 Locations and Presentations of Meningiomas

Location	Presenting Manifestation
Parasagittal	Urinary incontinence, dementia, gradual paraparesis, seizures
Lateral convexity	Variable depending on structures compressed, including slow hemiparesis, speech abnormalities
Olfactory groove	Anosmia, visual disturbance, dementia, Foster-Kennedy syndrome
Suprasellar	Hormonal failure, bitemporal hemianopsia, optic atrophy
Sphenoid ridge	Extraocular nerve paresis, exostoses, proptosis, seizures

From Goetz CG, Pappert EJ: *Textbook of clinical neurology,* Philadelphia, 1999, WB Saunders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Other well-circumscribed intracranial tumors that involve the dura or subdural space:

- Acoustic schwannoma (typically at the pontocerebellar junction)
- Ependymoma, lipoma, and metastases within spinal cord
- Metastatic disease from lymphoma/adenocarcinoma
- Inflammatory disease such as sarcoidosis and Wegener granulomatosis
- Infections such as tuberculosis

WORKUP

Imaging studies with CT or MRI, followed by surgical removal with histologic confirmation

LABORATORY TESTS

According to the World Health Organization (WHO) classification, there are nine benign histologic variants (account for 90% of all meningiomas) and four variants associated with increased recurrence and rates of metastasis. 80% of meningiomas are classified as benign meningiomas or WHO grade I.

IMAGING STUDIES

- Cranial CT scanning or MRI can detect and determine the extent of meningiomas (Fig. 1). CT can show hyperostosis and/or intratumoral calcifications. MRI with contrast (Fig. 2) is the imaging modality of choice to demonstrate the dural origin of the tumor in most cases, with the characteristic "tail" sign that tracks along the dura outside brain parenchyma.
- On nonenhanced scans, meningiomas are typically isodense or slightly hyperdense to

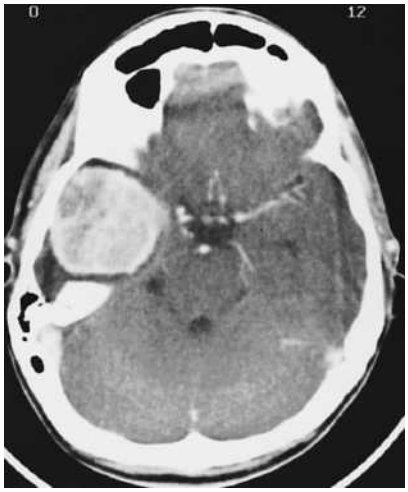

FIG. 1 Contrast-enhanced computed tomography scan demonstrates a large contrast-enhancing right sphenoid wing meningioma. (From Specht N [ed]: *Practical guide to diagnostic imaging,* St Louis, 1998, Mosby.)

FIG. 2 Magnetic resonance imaging picture of a posterior fossa meningioma, demonstrated an extra-axial homogeneously contrast-enhanced mass arising from the tentorium and compressing the cerebellar hemisphere. (From Goetz CG, Pappert EJ: *Textbook of clinical neurology,* Philadelphia, 1999, WB Saunders.)

brain and are homogeneous in appearance. They show homogeneous contrast enhancement; gadolinium can facilitate imaging of smaller additional lesions that are missed on unenhanced images.
- Indistinct margins, marked edema, mushroom-like projections from tumor, brain parenchymal infiltration, and heterogeneous enhancement are suggestive of more aggressive behavior.
- Positron emission tomography (PET) scan may help in predicting the aggressiveness of the tumor and the potential for recurrence, but it is not used routinely.

Rx TREATMENT

Primary management depends on signs or symptoms, age of patient, and location and size of tumor. Observation may be appropriate if tumors are discovered incidentally and/or if growth is indolent and unlikely to cause symptoms.

PHARMACOLOGIC THERAPY

- Although a variety of chemotherapeutic agents have been studied, such as hydroxyurea, there is no established effective systemic therapy.
- Inhibition of hormone receptors, such as progesterone, estrogen, and androgen, has failed to demonstrate clinical benefit.
- Treatment with molecularly targeted approaches, such as angiogenesis inhibition, is currently under way.

NONPHARMACOLOGIC THERAPY

- The mainstay of treatment for meningiomas remains surgical removal. Complete resection is usually attempted, when feasible. After total excision, recurrence rates of 0% to 20% have been observed, while 20% to 50% of patients recur within 5 yr of a subtotal resection.
- Active surveillance to monitor for tumor recurrence is important.
- Radiation therapy is the only validated form of adjuvant therapy and may be beneficial in patients with incomplete resections or inoperable tumors. Stereotactic radiosurgery can provide local control with more limited toxicity.

ACUTE GENERAL Rx

- For lesions that cause significant mass effect, steroids are sometimes used to decrease brain edema.
- Anticonvulsants are used if the patient presents with seizures.

CHRONIC Rx

- Prophylactic use of anticonvulsants is not recommended in patients without a history of seizures.
- There is limited data on the efficacy of traditional chemotherapy, and the evidence is largely anecdotal. The most extensively evaluated agents are hydroxyurea, mifepristone (RU486), and interferon alfa-2b. Recently, somatostatin analogs have been evaluated in multicenter clinical trials, primarily in malignant meningiomas.

DISPOSITION

- Estimated surgical mortality is 7%. Significant morbidity and mortality can be observed in meningiomas with otherwise favorable pathology secondary to unfavorable location (e.g., skull base). 10-yr relative survival is 80.4% in the cerebral meninges vs. 93.2% in spinal meninges.
- Long-term outcome varies based on pathology, tumor grade, location, and completeness of resection. 10-yr relative survival for nonmalignant meningioma is 81.5%, with highest survivability in the youngest age group. 10-yr relative survival for malignant meningioma is 53.5%, with similar age-based effects.
- Most incidentally discovered meningiomas remain asymptomatic and have a slow rate of growth. Calcified tumors may be less likely to progress than noncalcified ones.
- Meningiomas may recur after surgical resection or progress to a higher grade. Risk factors for recurrence include multiple allelic chromosomal losses, local brain invasion, high rate of mitosis, and highly anaplastic features.

REFERRAL

- Neurosurgical consultation for all cases
- Neurology, radiation oncology, and oncology consults depending on presence of other sequelae or in the setting of recurrence

PEARLS & CONSIDERATIONS

COMMENTS

- Many meningiomas are discovered incidentally; most are benign and remain asymptomatic. A first follow-up MRI should be performed 3 to 6 mo after the tumor is identified to rule out an atypical meningioma with rapid growth.
- "Dural tail," which is the thickening of the dura adjacent to the mass, is a classic finding on neuroimaging studies.
- Individuals with neurofibromatosis type 2 are at high risk to develop meningiomas.

BASIC INFORMATION

DEFINITION

Bacterial meningitis is an inflammation of meninges with increased intracranial pressure, and pleocytosis or increased WBCs in cerebrospinal fluid (CSF) secondary to bacteria in the pia-subarachnoid space and ventricles, leading to neurologic sequelae and abnormalities.

SYNONYMS

Spinal meningitis
Bacterial meningitis

ICD-10CM CODES

G00.9	Bacterial meningitis, unspecified
G00.8	Other bacterial meningitis
G01	Meningitis in bacterial diseases classified elsewhere

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 1.3 to 2.0 cases/100,000 persons; 1.2 million cases per yr in the world; 135,000 deaths annually worldwide. The rate of bacterial meningitis declined dramatically in the U.S. starting in the early 1990s with the introduction of the *Haemophilus influenzae* type b (Hib) vaccine and in 2000 with the introduction of the conjugate pneumococcal vaccine.
PREDOMINANT SEX: Male = female
PREDOMINANT AGE: All ages, neonate to geriatric

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Fever
- Headache
- Neck stiffness, nuchal rigidity, meningismus
- Altered mental state, lethargy
- Vomiting, nausea
- Photophobia
- Seizures
- Coma; lethargy, stupor
- Rash: Petechial and purpuric lesions (Fig. E1) associated with meningococcal infection, purpura fulminans
- Myalgia
- Cranial nerve abnormality (unilateral)
- Papilledema
- Dilated, nonreactive pupil(s)
- Posturing: Decorticate/decerebrate
- Physical examination findings of Kernig sign and Brudzinski sign (Fig. E2) in adults with meningitis are often seen later in the course of disease and may not be helpful in determining early meningeal inflammation

ETIOLOGY

The bacterial etiology of meningitis depends on the age of the patient. *Neisseria meningitidis* is now more common than *Haemophilus influenzae* as a cause of bacterial meningitis in children as well as adults, and streptococci (*Streptococcus pneumoniae*) are still common causes of community-acquired bacterial meningitis. *H. influenzae* is the cause of >30% of cases of meningitis (usually in infants and children <6 yr of age). It is associated with sinusitis, otitis media.

- Neonates: Group B streptococcus, gram-negative rods such as *E. coli, Listeria monocytogenes*
- Infants ≥1 mo and <3 mo: Group B streptococci (40%), gram-negative rods (30%), *Streptococcus pneumoniae* (14%), and *Neisseria meningitidis* (12%)
- Infants ≥3 mo and <3 yr:
  1. *S. pneumoniae* (45%)
  2. *N. meningitidis* (34%)
  3. *S. agalactiae* (group B streptococci) (11%)
  4. *H. influenzae*
  5. *E. coli*
- Ages ≥3 yr and <10 yr:
  1. *S. pneumoniae* (47%)
  2. *N. meningitidis* (32%)
- Ages ≥10 yr and <19 yr
  1. *N. meningitidis* (55%)
  2. *S. pneumoniae*
- Adults: *S. pneumoniae, N. meningitidis,* and *Streptococcus agalactiae* (third most common cause in adults).
- *Listeria monocytogenes* is uncommon in the general population but is often seen in older adults and in those with cell-mediated immune deficiencies.
- People with HIV/AIDS are at increased risk for invasive meningococcal disease (IMD).

DIAGNOSIS

Diagnostic approach is based on patient presentation and physical examination (Fig. 3). Lumbar puncture should be performed as soon as possible. Key elements to diagnosis are CSF evaluation and CT scan or MRI if the patient is in a coma or has focal neurologic deficits, pupillary abnormalities, or papilledema. Table 1 describes tests of CSF in patients with suspected CNS infection.

DIFFERENTIAL DIAGNOSIS (BOX E1)

- Endocarditis, bacteremia
- Intracranial tumor
- Lyme disease
- Brain abscess
- Partially treated bacterial meningitis
- Medications
- SLE
- Seizures
- Acute mononucleosis
- Other infectious meningitides
- Neuroleptic malignant syndrome
- Subdural empyema
- Subarachnoid hemorrhage (Table 2)
- Rocky Mountain spotted fever

WORKUP

CSF examination (Table 3):

- Opening pressure >100 to 200 mm Hg
- WBC usually >1000/mm^3
- Neutrophilic predominance: >80%
- Gram stain of CSF: Positive in 60% to 90% of patients
- CSF protein: >50 mg/dl
- CSF glucose: <40 mg/dl
- Culture: Positive in 65% to 90% of cases
- Multiplex PCR assay for detection of *S. pneumoniae, H. influenza, N. meningitidis,* and *L. monocytogenes* offer 100% sensitivity and 98% specificity.

LABORATORY TESTS

Blood culturing, WBC with differential, and CSF examination (see "Workup")

IMAGING STUDIES

- Guidelines from the Infectious Society of America recommend CT of brain before lumbar puncture in patients presenting with:
  1. A high clinical suspicion for subarachnoid hemorrhage
  2. New focal neurologic deficit
  3. Papilledema
  4. Seizures within a wk
  5. Altered mental status
  6. History of central nervous system disease (e.g., tumor, stroke)
  7. Immunodeficiency
  8. Age 60 or older

TREATMENT

Empiric therapy (Table 4) is necessary with IV antibiotic treatment if patient has purulent CSF fluid at time of lumbar puncture, is asplenic, or has signs of DIC/sepsis pending gram stain and culture results. Try to obtain blood and CSF cultures before starting antimicrobial therapy, but do not delay therapy if obtaining them is not possible. If CT scan is indicated (see "Imaging Studies" for indications) it should not delay empiric antibiotic therapy. Therapy after gram stain pending cultures is recommended for the following:

- Neonates: Ampicillin: 200 to 400 mg/kg per day divided q6 to 8 hr plus gentamicin: 7.5 mg/kg IV in three divided doses plus a third-generation cephalosporin: cefotaxime or ceftriaxone
- 1 to 23 mo: Vancomycin: 60 mg/kg per day IV (maximum up to 4 g/day) divided in four doses plus third-generation cephalosporin: Ceftriaxone: 100 mg/kg (maximum dose 4 g/day) in one or two divided doses or cefotaxime: 300 mg/kg per day IV (maximum dose of 12 g/day) in three or four divided doses
- Children: Vancomycin: 60 mg/kg per day IV (maximum dose 4 g/day) in four divided doses plus third-generation cephalosporin: Ceftriaxone 100 mg/kg per day IV (maximum 4 g/day) or cefotaxime: 300 mg/kg IV (maximum dose of 12 g/day) in three or four divided doses
- Adults: Vancomycin: 15 to 20 mg/kg IV every 8 to 12 hours plus third-generation cephalosporin: Ceftriaxone: 2 g IV q12h or cefotaxime: 2 g IV q4 to 6 hr. For adults over 50 yr of age also add ampicillin 2 g IV every 4 hr to cover *Listeria*
- Immunocompromised patients: Vancomycin *plus* ampicillin *plus* either cefepime 2 g IV

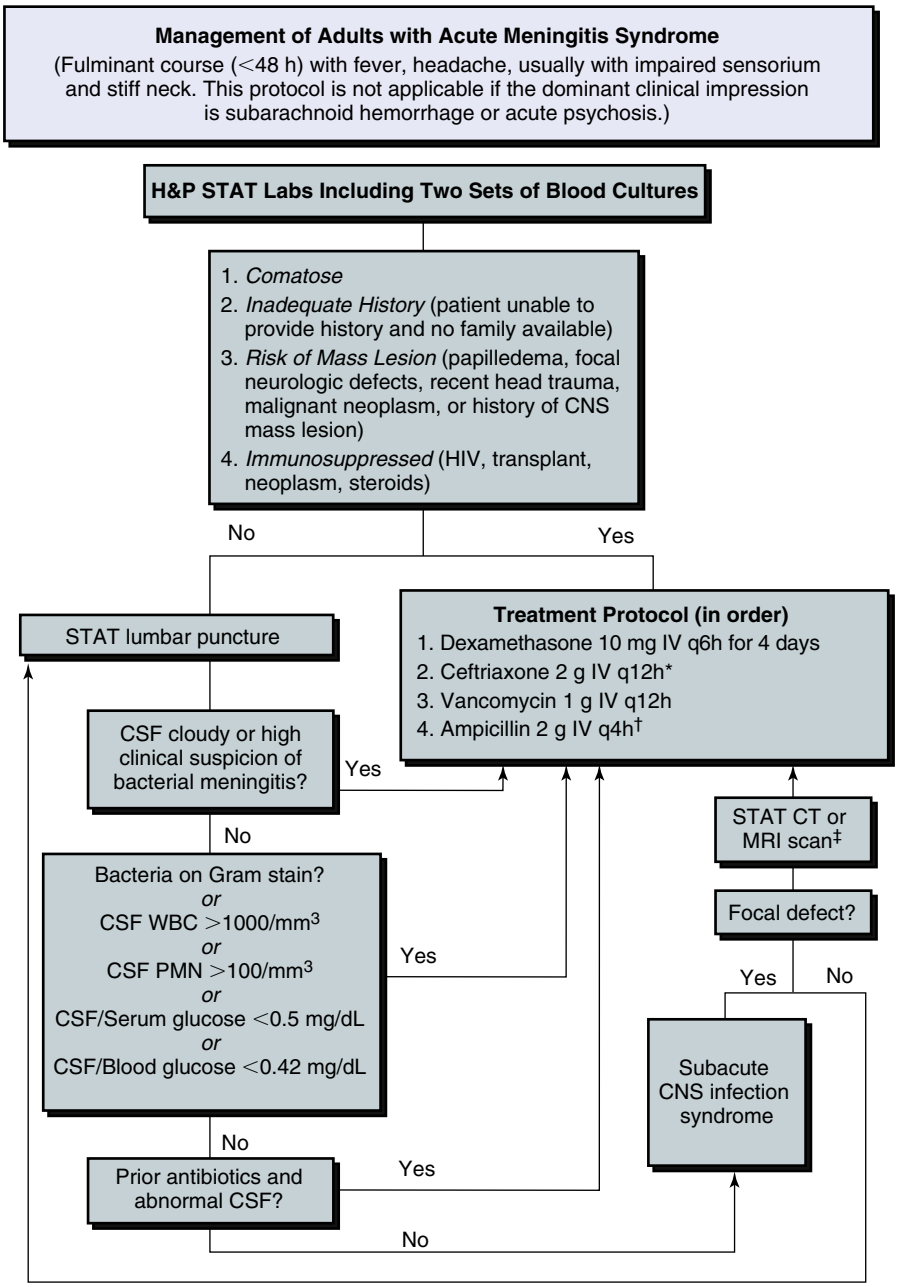

FIG. 3 Algorithm for management of adult patients with acute meningitis syndrome. *For severe cephalosporin allergy, consider meropenem or moxifloxacin. †Ampicillin is indicated if there is a history of alcoholism, organ transplant, malignancy, pregnancy, or age older than 50 yr. For penicillin-allergic patients, an alternative is trimethoprim-sulfamethoxazole. ‡Consider magnetic resonance imaging *(MRI)* if the patient is known or suspected to have human immunodeficiency virus *(HIV),* if it can be obtained rapidly. *CNS,* Central nervous system; *CSF,* cerebrospinal fluid; *CT,* computed tomography; *H&P,* history and physical examination; *PMN,* polymorphonuclear leukocyte; *WBC,* white blood cell. (From Vincent JL et al: *Textbook of critical care,* ed 6, Philadelphia, 2011, Saunders.)

every 8 hr to cover *Pseudomonas* or meropenem 2 g IV q8h for adults, which also covers *Pseudomonas*

Use of corticosteroids in adults:

- Dexamethasone 0.15 mg/kg q6h for first 4 days of therapy should be used for adults in developed countries with known or suspected bacterial meningitis. Decreased mortality and neurologic sequelae (hearing loss , etc.) are seen with adjunct therapy in patients with pneumococcal meningitis but not other pathogens. The benefit of dexamethasone is less clear in developing countries with high HIV prevalence and malnutrition or with delayed clinical presentations.
- Dexamethasone also benefits children with Hib meningitis if given at the same time or before the first dose of the antibiotic: 0.15 mg/kg per dose q6h for 2 to 4 d. The use and benefit of corticosteroids in children with suspected or pneumococcal or meningococcal meningitis to prevent neurologic sequelae is not as clear and should be individualized after analysis of risk and benefits.

TABLE 1 Tests of Cerebrospinal Fluid in Patients with Suspected Central Nervous System Infection

Routine Tests
White blood cell count with differential
Red blood cell count[a]
Glucose concentration[b]
Protein concentration
Gram stain
Bacterial culture
Selected Specific Tests Based on Clinical Suspicion
Viral culture[c]
Smears and culture for acid-fast bacilli
Venereal Disease Research Laboratory (VDRL)
India ink preparation
Cryptococcal polysaccharide antigen
Fungal culture
Antibody tests (IgM or IgG, or both)[d]
Nucleic acid amplification tests (e.g., polymerase chain reaction)[e]
Cytology[f]
Flow cytometry

[a]Should be checked in the first and last tubes; in patients with a traumatic tap, there should be a decrease in the number of red blood cells with continued flow of cerebrospinal fluid (CSF). See text for the formula for determining whether the numbers of CSF red blood cells and white blood cells are consistent with a traumatic tap.
[b]Compare with serum glucose drawn just before lumbar puncture.
[c]Yield of viral culture may be low.
[d]May be useful for specific causes of meningitis and encephalitis.
[e]Most useful for specific viral causes of encephalitis and causes of chronic meningitis.
[f]In patients with suspected malignancy.
From Bennett JE, Dolin R, Blaser MJ: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases,* ed 8, Philadelphia, 2015, Saunders.

TABLE 2 Acute Bacterial Meningitis and Subarachnoid Hemorrhage

Finding	Frequency (%)
Acute Bacterial Meningitis	
Neck stiffness	84
Fever	66-97
Altered mental status	55-95
Kernig or Brudzinski sign	61
Focal neurologic signs	9-37
Seizures	5-28
Petechial rash	3-52
Subarachnoid Hemorrhage	
Neck stiffness	21-86
Seizures	7-32
Altered mental status	29-64
Focal neurologic findings	10-36
Fever	6
Preretinal hemorrhage	4

Diagnostic standard: For *meningitis,* cerebrospinal fluid pleocytosis and microbiologic or postmortem data supporting bacterial meningitis; for *subarachnoid hemorrhage,* computed tomography or lumbar puncture.
From McGee, S: *Evidence-based physical diagnosis,* ed 4, Philadelphia, 2018, Elsevier.

DISPOSITION

Bacterial meningitis is a reportable disease that needs to be reported to local health authorities. Droplet precautions should be used for first 24 hr of therapy for suspected or confirmed *N. meningitidis* infection.

REFERRAL

- To a neurologist if persistent neurologic sequelae develop after bacterial meningitis
- To an infectious disease consultant if a patient has recurrent bacterial meningitis; such patients deserve a workup for an anatomic (CSF dural leak) or immunologic defect (complement defect, hyposplenism, immunoglobulin deficiency)

TABLE 3 Typical Cerebrospinal Fluid Findings in Patients with Selected Infectious Causes of Meningitis

Cause of Meningitis	White Blood Cell Count (cells/mm^3)	Primary Cell Type	Glucose (mg/dl)	Protein (mg/dl)
Viral	50-1000	Mononuclear[a]	>45	<200
Bacterial	1000-5000[b]	Neutrophilic[c]	<40[d]	100-500
Tuberculous	50-300	Mononuclear[e]	<45	50-300
Cryptococcal	20-500[f]	Mononuclear	<40	>45

[a]May be neutrophilic early in presentation.
[b]Range from <100 to >10,000 cells/mm^3.
[c]About 10% of patients have cerebrospinal fluid lymphocyte predominance.
[d]Should always be compared with a simultaneous serum glucose; ratio of CSF to serum glucose is ≤0.4 in most cases.
[e]May see a "therapeutic paradox," in which a mononuclear predominance becomes neutrophilic during antituberculous therapy.
[f]More than 75% of patients with acquired immunodeficiency syndrome have <20 cells/mm^3.
From Bennett JE, Dolin R, Blaser MJ: *Mandell, Douglas, and Bennett's principles and practice of infectious diseases, ed 8, Philadelphia,* 2015, Saunders.

PEARLS & CONSIDERATIONS

COMMENTS

- Patients with bacterial meningitis often require ICU care either to manage complications evident on presentation or for monitoring for any complications that may subsequently develop during their course. Criteria for admission to an ICU are summarized in Table 5.
- Nosocomial bacterial meningitis may result from invasive procedures (e.g., placement of ventricular catheters, lumbar puncture, craniotomy, spinal anesthesia). Treatment of this different spectrum of microorganisms requires empirical antimicrobial therapy with vancomycin plus either cefepime, ceftazidime, or meropenem. In cases of basilar skull fracture, effective empirical antimicrobial therapy consists of vancomycin plus a third-generation cephalosporin.
- False-positive elevations of CSF where blood cell counts can be found after traumatic lumbar puncture or in patients with intracerebral or subarachnoid hemorrhage in which RBCs and WBCs are introduced into the

TABLE 4 Empiric Treatment of Suspected Bacterial Meningitis in Adults[a,1,2,3,4]

Host Factors to Consider

Age >50 yr? Risk for *Listeria monocytogenes* and aerobic gram-negative rods

Immune suppression? Includes host defects (e.g., HIV, alcoholism, lymphoma) and treatment-related (e.g., posttransplant, corticosteroids)

Health care–associated? Includes trauma, postneurosurgical, shunt- or ventriculostomy-related

Life-threatening penicillin/β-lactam allergy? Aztreonam or fluoroquinolone alternatives for gram-negative rods; trimethoprim-sulfamethoxazole an alternative for *L. monocytogenes*

Host	Likely Pathogens	Empiric Therapy	Additional Considerations
Age 15-50 yr Without Immune Suppression	*Streptococcus pneumoniae, Neisseria meningitidis*, group B β-hemolytic streptococci	Vancomycin + third-generation cephalosporin[b]	Adjuvant dexamethasone Consider rifampin if high rates of cephalosporin-resistant *S. pneumoniae*
Age ≥50 yr Without Immune Suppression	*S. pneumoniae, N. meningitidis,* group B β-hemolytic streptococci, *L. monocytogenes,* aerobic gram-negative rods	Vancomycin + ampicillin + third-generation cephalosporin[b]	Adjuvant dexamethasone Consider rifampin if high rates of cephalosporin-resistant *S. pneumoniae*
Immune Suppression	*S. pneumoniae, N. meningitidis,* group B β-hemolytic streptococci, *L. monocytogenes*, *Staphylococcus aureus*, aerobic gram-negative rods including *Pseudomonas aeruginosa*	Vancomycin + ampicillin + cefepime or meropenum[c]	Adjuvant dexamethasone Consider rifampin if high rates of cephalosporin-resistant *S. pneumoniae*
Health Care–Associated: Trauma, Postneurosurgical, or Shunt-Associated[c]	*S. aureus*, coagulase-negative staphylococci, aerobic gram-negative rods including *P. aeruginosa*	Vancomycin + ceftazidime or cefepime or meropenem[c]	Dexamethasone not indicated Consider rifampin for staphylococci Consider intrathecal therapy for shunt-/ventriculostomy-associated infection
Health Care–Associated: Basilar Skull Fracture	*S. pneumoniae*, *Haemophilus influenzae,* group A β-hemolytic streptococci	Vancomycin + third-generation cephalosporin[b]	Adjuvant dexamethasone Consider rifampin if high rates of cephalosporin-resistant *S. pneumoniae*

[a]Age older than 15 yr.
[b]Third-generation cephalosporin: ceftriaxone 2 g q12h or cefotaxime 2 g q4-6h.
[c]Dosing of other agents (modified for renal insufficiency): vancomycin targeted to vancomycin trough levels of 15-20 μg/ml; ampicillin 2 g q4h; ceftazidime 2 g q8h; cefepime 2 g q8h; meropenem 2 g q8h.

TABLE 5 Major Complications of Bacterial Meningitis Requiring ICU Level of Care for Monitoring and Management[1,2,3,4,5]

Type of Complication	Etiologies, Prevalence	Management Strategies
Neurologic Complications		
Increasing intracranial pressure	Brain edema, 6%-10%	Strategies: osmotic diuresis, intracranial pressure monitoring, head of bed elevation, prophylactic lumbar drain Glycerol and hypothermia not beneficial and may result in higher mortality
Hydrocephalus	Communicating hydrocephalus, 3%-8% Obstructive hydrocephalus uncommon	Repeated lumbar puncture, lumbar drain, ventriculostomy
Focal neurologic deficits	Arterial infarct or vasculitis, 10%-15% Venous infarction, 3%-5% Hearing loss, 14%-30% Cranial nerve deficits, especially eighth nerve, 15%-30% Hemorrhage, <1% Brain abscess, subdural empyema <1%	Radiographic studies to look for focal intracranial complications Administer dexamethasone for suspected pneumococcal meningitis to decreases risk of hearing loss
Seizures	Multiple etiologies, 14%-33%	Continuous EEG monitoring, antiepileptic agents Prophylactic antiepileptic agents not routinely recommended
Agitation	Common	Careful sedation
Other Complications		
Hyponatremia	Up to 25%-30%	? Hypertonic saline solution Presence of hyponatremia did not affect outcome
Sepsis and cardiorespiratory failure	38%	Hemodynamic support, mechanical ventilation
Pneumonia	17%, most often with *Streptococcus pneumoniae*	Ventilatory support

subarachnoid space. In those instances, the following formula should be used as a correction factor for the true WBC count in the presence of CSF RBCs:

$$\text{Adjusted WBC in CSF} = \text{Actual WBC in CSF} - \frac{\text{WBC in blood} \times \text{RBC in CSF blood}}{\text{RBC in blood}}$$

In the previous equation, the amount being subtracted is the predicted CSF WBC that would occur if all the CSF WBCs were the result of blood contamination.[1]

[1]Bennett JE et al: *Mandell, Douglas and Bennett's principles and practice of infectious diseases, ed 8,* Philadelphia, 2015, Saunders, p 1093.

- Prevention of meningitis can be achieved through chemoprophylaxis of close contacts (household members and anyone exposed to oral secretions).
- Effective medications are rifampin 10 mg/kg PO bid for 2 days or ceftriaxone 250 mg IM single dose in patients older than age 12; 125 mg IM if age 12 or younger.
- Ciprofloxacin 500 mg for prevention of *Neisseria* meningitis can be given to patients older than 18 yr who cannot tolerate rifampin to eradicate pharyngeal colonization.
- Menactra: A protein-conjugate vaccine against serogroup A, C, Y, W-135 capsular polysaccharides is available for adults (up to 55 yr) and children older than 2 yr.
- Two new vaccines for *Neisseria* meningitis serogroup B (MenB) are now available: Bexsero and Trumenba.
- Children with cochlear implants are at increased risk of developing bacterial meningitis.
- Patients on eculizumab (Soliris) are at high risk for invasive meningococcal disease and should receive Menactra and a MenB vaccine and may need lifelong antibiotic prophylaxis as well.

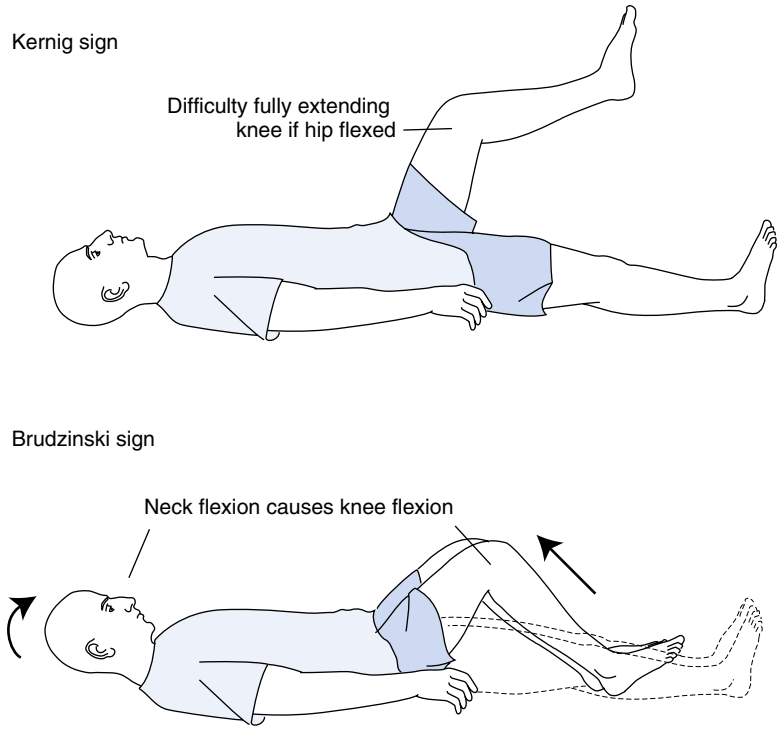

FIG. E2 Kernig sign and Brudzinski sign. In Kernig sign *(top),* the patient resists full extension of the knee when the knee and hip are first flexed (patient's left leg), although the knee extends normally if the hip is extended (patient's right leg). In Brudzinski sign *(bottom),* flexion of the patient's neck causes the hips and knees to flex, pulling both legs up toward the chest. (From McGee S: *Evidence-based physical diagnosis,* ed 4, Philadelphia, 2018, Elsevier.)

BOX E1 Differential Diagnosis Meningococcemia

Infectious

- Rocky Mountain spotted fever
- Ehrlichiosis
- Streptococcal *pneumoniae* sepsis
- *Haemophilus influenzae* type b sepsis
- Group A streptococcus sepsis
- *Staphylococcus aureus* sepsis
- Other bacterial sepsis with disseminated intravascular coagulation (i.e., enteric gram-negative organisms)
- Infective endocarditis
- Gonococcemia
- Rat bite fever
- Typhus
- Secondary syphilis

Noninfectious

- Henoch-Schönlein purpura
- Acute hemorrhagic edema of infancy
- Idiopathic thrombocytopenic purpura
- Collagen vascular disease
- Neoplastic processes

(From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.)

Meningitis, Fungal

BASIC INFORMATION

DEFINITION

Fungal meningitis is an infection of the meninges and/or central nervous system that is usually more subacute than acute and caused by a variety of different fungi or molds. The most common causes in the U.S. are *Cryptococcus neoformans* and *Coccidioides immitis* meningitis, but there was a recent multistate outbreak in the U.S. of fungal central nervous system infections and septic arthritis mostly caused by *Exserohilum rostratum* transmitted via epidural or paraspinal injections of methylprednisolone produced at a single compounding pharmacy. See Table E1. This chapter covers this outbreak. Also see chapters on Cryptococcosis and Coccidioidomycosis.

SYNONYMS

Fungal central nervous system infections
Fungal meningitis

ICD-10CM CODES

B37.5+	Candidal meningitis
B38.4+	Coccidioidomycosis meningitis
B39.3	Disseminated histoplasmosis capsulati
B40.7	Disseminated blastomycosis
B45.1	Cerebral cryptococcosis
B46.1	Rhinocerebral mucormycosis
B47.7	Disseminated sporotrichosis
B49	Unspecified mycosis

EPIDEMIOLOGY & DEMOGRAPHICS

- Outbreak started in September 2012.
- As of October 2013 there were 751 cases, including 64 deaths. No new cases were anticipated.
- Cases have been reported in 20 states, but Michigan, Tennessee, and Indiana have had the most cases.
- Some 14,000 patients had been injected with vials of methylprednisolone that were potentially contaminated with the mold.

INCIDENCE: Overall attack rate is calculated at 4.4 cases per 100 persons potentially exposed.

PREDOMINANT AGE AND SEX:

- Median age of affected patient is 64 yr (range 16 to 92).
- Females represent 60% of the cases.

PEAK INCIDENCE: Occurs within 6 wk of receiving an epidural or paraspinal injection of methylprednisolone contaminated with the mold, but cases have been detected after 3 mo.

RISK FACTORS: The source of this outbreak was traced to a single compounding pharmacy (New England Compounding Center). *E. rostratum* has been detected in two of three implicated lots of unopened vials of preservative-free methylprednisolone.

- 17,000 vials were potentially contaminated.
- 75 health care facilities (hospital and outpatient treatment centers) in 23 states received vials with lots that were subsequently recalled.
- Infection is only acquired via injection of the steroid and *not* transmitted person to person.

TABLE E1 Mycoses as a Cause of Fungal Meningitis

Cryptococcus neoformans and *Cryptococcus gattii*
Coccidioides immitis
Histoplasma capsulatum
Candida albicans and other *Candida* species
Sporothrix schenckii
Blastomyces dermatitidis
Molds: *Scedosporium, Aspergillus*
Molds with dark cell walls containing melanin: Many species including:
Cladophialophora
Exophiala species
Exserohilum rostratum

- Eventually all products manufactured at that facility were recalled and the facility closed.
- Contamination was felt to have occurred due to lack of sterility controls in manufacturing.
- Green-black material was visibly seen in 83 of 321 vials from one of the recalled lots.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

Most patients present 1 to 4 wk after injection.

- Meningitis, stroke, and injection site infections.
  1. Meningitis: New or worsening headache, neck stiffness, photophobia.
  2. Stroke: Neurologic deficit with weakness, slurred speech, vertigo, ataxia, or diplopia. Stroke usually involves posterior circulation causing a basilar stroke.
  3. Injection site infections: Epidural abscess, arachnoiditis, discitis, vertebral osteomyelitis, or persistent back pain.
  4. Peripheral joint infections: 35 patients have developed only a peripheral joint infection due to an injection into that joint with a steroid from a contaminated lot.
- Pathogenesis: The steroid itself may impair local host defenses and facilitate the fungal infection into the central nervous system. The fungus accesses the cerebrospinal fluid (CSF) and spreads upward to the basal cisterns and then invades the basilar arteries.
- Fever has not been a consistent symptom.
- Some patients were found to have injection site infections on screening MRI but had no clinical symptoms yet.

ETIOLOGY

- Only about a third of the clinical cases have a proven culture result.
- *Exserohilum rostratum* is the documented cause in about 30% of clinical cases.
  1. Part of the Dematiaceae fungi group (darkly pigmented due to melanin)
  2. Found in soil and part of living or dead plant material
  3. Sensitive to voriconazole and amphotericin B but resistant to fluconazole
- Thirteen other mold species have been isolated in patients including *Aspergillus* species, *Alternaria* species, *Cladosporium* species, *Penicillium* species, and other species.
- Four different types of molds were isolated from the contaminated vials.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Meningitis: Bacterial, viral, or mycobacterial pathogens
- Stroke: Cardioembolic stroke, hemorrhagic stroke
- Tumors of the central nervous system
- Epidural abscess by bacterial pathogens
- Osteomyelitis of bacterial etiology

WORKUP

- A negative culture from a clinical specimen does not rule out the infection.
- Local health department should be contacted if case suspected.

LABORATORY TESTS

- CSF: If meningitis suspected perform lumbar puncture (LP). Obtain at least 10 to 20 ml of CSF.
  1. Obtain routine tests: Gram stain, culture, cell count, protein, glucose.
  2. At least 10 cc for fungal culture and hold for a minimum of 2 wk.
  3. Send unspun CSF to CDC for a polymerase chain reaction (PCR) for *E. rostratum.*
  4. Fungal CSF characteristics are summarized in Table E2.
- Other tests: Routine CBC with differential, blood urea nitrogen/creatinine (BUN/CR), liver function tests.

IMAGING STUDIES

Neuroimaging via MRI or MRI/MRA or CT can detect:

- Infarcts/strokes
- Large vessel involvement of the posterior circulation
- Dural and leptomeningeal enhancement
- Arachnoiditis
- Osteomyelitis/discitis of the spine
- Epidural abscess

TREATMENT

There are four cornerstones of the management of mold infections of the CNS: early diagnosis, administration of antifungal chemotherapy, neurosurgical assessment and intervention, and management of immunologic impairment.

ACUTE GENERAL Rx

Will depend on site of infection and severity:

- Meningitis: Voriconazole with or without liposomal amphotericin B.
  1. Voriconazole: 6 mg/kg q12h IV for severe cases or oral for mild cases has good penetration into CSF; side effects include changes in color vision or hallucinations.
  2. Liposomal amphotericin B (AmBisome): 7.5 mg/kg IV q24h can be added to voriconazole for the most severe cases or for patients who are not responding to

TABLE E2 Fungal Cerebrospinal Fluid Characteristics

Organism	WBCs	Protein	Glucose	Smears	Serology	Cultures
Blastomyces	Variable up to 15,000 cells/mm^3 with PMNs or lymphocytes	Elevated up to 300 mg/dl	Normal or low	Rare on smear	No good serology	CSF cultures rarely positive; increased yield with ventricular taps
Candida	Mean 600 cells/mm^3 up to 1900 cells/mm^3 with lymphocytes or PMNs	Elevated	Low or normal	40% positive on smears	Serology not helpful	CSF cultures useful
Coccidioides	100-750 WBCs, mostly lymphocytes	150-2000 mg/dl	21%-62% serum	Rare on smear	CSF CF antibody positive in 75%-95%	CSF cultures positive in 33%-60%
Cryptococcus	40-400 WBCs, mostly lymphocytes	High	Low	India ink positive in 25%-50%	CSF and serum cryptococcal antigen positive in 85%-90%	CSF cultures positive in 75%
Histoplasma	0-300 WBCs, lymphocytes, or PMNs; most 11-101/mm^3	Usually elevated, but can be normal	Usually low (<40 mg/dl) to normal	Rare on smear	Polysaccharide antigen in urine, blood, CSF positive in 61%	CSF cultures positive in 27%-65%

CF, Complement fixation; *CSF,* cerebrospinal fluid; *PMN,* polymorphonuclear leukocyte; *WBC,* white blood cells.
From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

voriconazole alone or relapse. Can cause nephrotoxicity that can be ameliorated by giving 1 L of IV normal saline prior to dose.

- Injection site infections: Epidural abscess, discitis, vertebral osteomyelitis, etc.
  1. Voriconazole: 6 mg/kg q12h IV or oral depending on presentation and can consider adding liposomal amphotericin B at 5 to 6 mg/kg IV q24h.

CHRONIC Rx

- Meningitis: Meningitis therapy should last at least 3 mo, but stroke or severe CNS disease may require 6 mo to 1 yr. Monitor liver function tests, and obtain a voriconazole trough concentration on day 5 of treatment that should be between >2 mcg/ml and <5 mcg/ml. Monitor for neurologic side effects of voriconazole. For patients on liposomal amphotericin B, kidney function and electrolytes (K+) need to be monitored frequently.
- Injection site infections: Therapy should last at least 3 to 6 mo.

DISPOSITION

Mortality has been about 8.8%, and highest risk factor is development of a stroke.

REFERRAL

- Infectious diseases physician for guidance on initial and long-term antifungal therapy
- Neurologist for evaluation and diagnosis
- Neuroradiologist for MRI/MRA interpretation

PEARLS & CONSIDERATIONS

PATIENT & FAMILY EDUCATION

This fungal disease is transmitted by the contaminated steroid injection and is not transmitted person to person and thus not contagious.

BASIC INFORMATION

DEFINITION

Viral meningitis is an acute febrile illness with signs and symptoms of meningeal irritation, usually with a lymphocytic pleocytosis of the cerebrospinal fluid (CSF) and negative CSF bacterial stains and cultures.

SYNONYMS

Aseptic meningitis
Viral meningitis

ICD-10CM CODES

A87.8 Other viral meningitis
A87.9 Viral meningitis, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS (TABLE 1)

INCIDENCE (IN U.S.): 11 cases/100,000 persons; leads to 26,000 to 42,000 hospitalizations per yr
PREDOMINANT SEX: Male = female
GENETICS: Those with abnormal humoral immunity and agammaglobulinemia have associated difficulty with viral clearance.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Fever
- Headache
- Nuchal rigidity
- Photophobia
- Myalgias
- Vomiting
- Rash

ETIOLOGY

- Enterovirus: 85% to 95% of all cases. Most common are coxsackie viruses and echoviruses
- Parechoviruses
- Mumps virus
- Measles
- Arboviruses from mosquitoes: Eastern equine encephalitis (EEE), West Nile, St. Louis
- Herpes: HSV-1, HSV-2, VZV, HHV-6, and HHV-7
- Acute HIV
- Lymphocytic choriomeningitis virus
- Adenovirus
- Cytomegalovirus (CMV) and Epstein-Barr virus (EBV)
- Other arthropod-borne viruses: Powassan virus
- Influenza A and B virus
- Box E1 summarizes etiologic agents, factors, and diseases associated with aseptic meningitis

DIAGNOSIS

The diagnostic approach is similar to that for bacterial meningitis (see "Meningitis, Bacterial"); the foremost need is to rule out bacterial meningitis with CSF evaluation. Presentation may be similar to that of meningitis with bacterial involvement.

DIFFERENTIAL DIAGNOSIS

- Bacterial meningitis
- Meningitis secondary to Lyme disease, tuberculosis (TB), syphilis, amebiasis, leptospirosis
- Rickettsial illnesses: Rocky Mountain spotted fever
- Migraine headache
- Medications
- Systemic lupus erythematosus (SLE)
- Acute mononucleosis/Epstein-Barr virus
- Seizures
- Carcinomatous meningitis

WORKUP

CSF examination:
- Usually shows pleocytosis
- Lymphocytic predominance (neutrophils in early stages)
- Opening pressure: 200 to 250 mm Hg H_2O ($\leq$250 mm/H_2O)
- WBC: 100 to 1000 mm^3
- Increased CSF protein (<200 mg/dl)
- Slightly decreased or normal CSF glucose (>45 mg/dl)
- Negative gram stain, cultures, CIE, latex agglutination
- Viral cultures or serologic testing may be diagnostic
- Polymerase chain reaction (PCR) for HSV or enterovirus (which could shorten duration of antibiotic treatment and hospitalization if bacterial meningitis was suspected); Multiplex or panel-based PCR tests that test for multiple viruses and bacteria at the same time in a single CSF sample are available
- Antibody detection in CSF for diagnosis of West Nile virus meningitis

LABORATORY TESTS

CBC with differential, blood culturing, and CSF examination (see "Workup")

IMAGING STUDIES

CT scan or MRI: If cerebral edema, focal neurologic findings develop.

TREATMENT

- No specific antiviral therapy for most viruses. Treatment is supportive unless herpes simplex virus (HSV) is detected, which would be treated with IV acyclovir: 10 mg/kg q8h in adults for 14 to 21 days. Up to 20 mg/kg q8h in children >12 yr.
- Empiric antibiotics may be given until CSF cultures exclude bacterial meningitis.

DISPOSITION

Viral meningitis is almost always an uncomplicated illness that will resolve; however, relapsing headache, myalgia, and weakness may occur for 2 to 3 wk after onset of symptoms.

PEARLS & CONSIDERATIONS

- Enteroviruses are the most common cause of viral meningitis and are transmitted by fecal-oral route and less commonly by the respiratory route. They are more common in summer and fall mos. From 2000 to 2005, the most common serotypes were coxsackie viruses A9, B5, and B1 and echoviruses 6, 9, 13, 18, and 30.
- Herpes simplex type 2 (HSV-2) can be a cause of a primary episode of meningitis and also be a cause of recurrent episodes of lymphocytic meningitis. HSV-2 meningitis presents most often without a history of genital herpes or genital symptoms. Recurrent aseptic meningitis, also known as Mollaret disease, is predominantly caused by HSV-2 infection.

BOX E1 Etiologic Agents, Factors, and Diseases Associated with Aseptic Meningitis

Viruses
- Adenoviruses (1, 2, 3, 5, 6, 7, 12, 14, 32)
- Arboviruses (in the U.S.: West Nile, St. Louis, California, Colorado tick fever, eastern equine, western equine, Venezuelan equine, and Powassan)[a]
- Coronaviruses
- Cytomegalovirus
- Encephalomyocarditis
- Enteroviruses (echoviruses, coxsackieviruses A and B, polioviruses, enteroviruses)
- Epstein-Barr
- Hendra and Nipah
- Herpes simplex type 1
- Herpes simplex type 2
- Human herpesvirus–6
- Human herpesvirus–7
- Human immunodeficiency virus (HIV-1)
- Human parechoviruses
- Human T-cell lymphotrophic virus (HTLV-1)
- Influenza A and B
- Lymphocytic choriomeningitis
- Measles
- Mumps
- Parainfluenza
- Parechoviruses
- Parvovirus B19
- Rhinoviruses
- Rotaviruses
- Rubella
- Varicella zoster
- Variola

Bacteria

Atypical Mycobacteria
- *Bartonella henselae*
- *Borrelia* spp. (relapsing fever)
- *Borrelia burgdorferi* (Lyme disease)
- *Brucella* spp.
- *Leptospira* spp. (leptospirosis)
- *Mycobacterium tuberculosis*
- *Nocardia* spp. (nocardiosis)

Pyogenic: Partially Treated
- *Treponema pallidum* (syphilis)

Rickettsia
- *Anaplasma phagocytophila*
- *Coxiella burnetii*
- *Ehrlichia chaffeensis*
- *Rickettsia rickettsii* (Rocky Mountain spotted fever)
- *Rickettsia prowazekii* (typhus)

Mycoplasma
- *Mycoplasma hominis*
- *Mycoplasma pneumoniae*

Chlamydia
- *Chlamydia pneumoniae*
- *Chlamydia psittaci*

Ureaplasma
- *Ureaplasma urealyticum*

Fungi
- *Blastomyces dermatitidis*
- *Candida* spp.
- *Coccidioides immitis*
- *Cryptococcus neoformans*
- *Histoplasma capsulatum*
- Other: *Acremonium* spp., *Alternaria* spp., *Aspergillus* spp., *Blastoschizomyces capitatus*, *Cephalosporium* spp., *Cladosporium trichoides, Drechslera hawaiiensis, Fusarium* spp., *Paecilomyces* spp., *Paracoccidioides brasiliensis, Penicillium marneffei, Phaeohyphomycosis, Pseudallescheria boydii, Sporothrix schenckii, Trichosporon beigelii, Ustilago* spp., *Zygomycetes* spp.

Parasites (Eosinophilic Meningitis)
- Flukes: *Paragonimus westermani,* schistosomiasis, fascioliasis
- Roundworms: *Angiostrongylus cantonensis, Gnathostoma spinigerum, Baylisascaris procyonis, Strongyloides stercoralis, Trichinella spiralis, Toxocara canis*
- Tapeworms: *Cysticercosis*
- Protozoa and free-living amoebae (noneosinophilic meningitis)
- *Acanthamoeba*
- *Naegleria fowleri*
- *Toxoplasma gondii* (toxoplasmosis)

Vaccine Associated
- Measles
- Mumps
- Polio
- Rabies
- Vaccinia

Parameningeal Infection

Malignancy
- Central nervous system tumor
- Leukemia

Immune Diseases
- Behçet syndrome
- Lupus erythematosus
- Sarcoidosis

Medications
- Antimicrobial agents (e.g., trimethoprim-sulfamethoxazole)
- Intrathecal injections (e.g., contrast media, antibiotics)
- Nonsteroidal antiinflammatory drugs
- Other drugs

Miscellaneous
- Epidermoid, dermoid, other cysts
- Foreign bodies (shunt, reservoir)
- Heavy metal poisoning
- Kawasaki disease

[a]In other areas of the world, many other arboviruses are important.

From Cherry JD et al: *Feigin and Cherry's textbook of pediatric infectious diseases,* ed 8, Philadelphia, 2019, Elsevier.

Meningomyelocele

BASIC INFORMATION

DEFINITION

Meningomyelocele is the most common type of open neural tube defect and is characterized by herniation of the spinal cord, nerves, or both through a bony defect of the spine covered only by a thin membrane or not covered.

SYNONYMS

Myelomeningocele
Spina bifida cystica

ICD-10CM CODES

Q05.2	Lumbar spina bifida with hydrocephalus
Q05.4	Unspecified spina bifida with hydrocephalus
Q05.7	Lumbar spina bifida without hydrocephalus
Q05.8	Sacral spina bifida without hydrocephalus
Q05.9	Spina bifida, unspecified

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE (IN U.S.): 4.6/10,000 births
PREDOMINANT SEX: Male = female
PEAK INCIDENCE: Newborn
GENETICS: Environmental and genetic factors have a joint role.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Evident at birth: A sac protruding in the lumbar region (Fig. E1, *A*)
- Severity of neurologic deficits depends on the location of the lesion along the neuraxis, and newborns may remain asymptomatic up to 6 wk
- Motor dysfunction in the legs below the level of the lesion
- Lack of bladder or bowel control in 97%
- Often associated with Chiari II malformation and resulting obstructive hydrocephalus

ETIOLOGY

- Failure of neural tube to close completely at about 4 wk gestation
- Associated with maternal valproate use, maternal diabetes, and prepregnancy obesity
- Growing recognition of role of environmental chemicals, including organic pollutants
- In the U.S., higher rates of neural tube defects reported among Hispanic women
- A small proportion of cases are associated with chromosomal or single-gene disorders

DIAGNOSIS

- Prenatal diagnosis through ultrasound and MRI is being made more frequently.
- Coexisting hydrocephalus detected by measurement of head size, ultrasonography, CT, or MRI.

DIFFERENTIAL DIAGNOSIS

- Teratoma
- Meningocele

WORKUP

- Evaluate for hydrocephalus.
- Evaluate for other congenital abnormalities, such as congenital heart disease, hydronephrosis, intestinal malformation, club foot, and skeletal deformities.

LABORATORY TESTS

Prenatal testing often reveals elevated alpha-fetoprotein in amniotic fluid or maternal serum.

IMAGING STUDIES

- MRI of spine (Fig. E1, *B* and *C*)
- X-ray studies of skull exhibit craniolacunia, a honeycombed pattern associated with hydrocephalus (not routinely performed)
- CT or MRI of head: May reveal hydrocephalus

TREATMENT

- Surgical closure of myelomeningocele is performed soon after birth
- Control of hydrocephalus (shunt)
- Management of urinary incontinence (bladder catheterization)

ACUTE GENERAL Rx

- Immediate goal after delivery is to close defect and prevent infection; surgery usually performed within 24 hours of birth
- Shunt placement for obstructive hydrocephalus
- Treatment of seizures, if present

CHRONIC Rx

- Follow closely for development of hydrocephalus
- Bladder catheterization
- Long-term management of neurologic sequelae
- Avoid use of latex-containing products to prevent development of latex allergy

DISPOSITION

Followed by a team of specialists including neurosurgeons, urologists, orthopedists, nurses, and physical therapists. Table E1 summarizes prognosis based on motor level spinal cord segment.

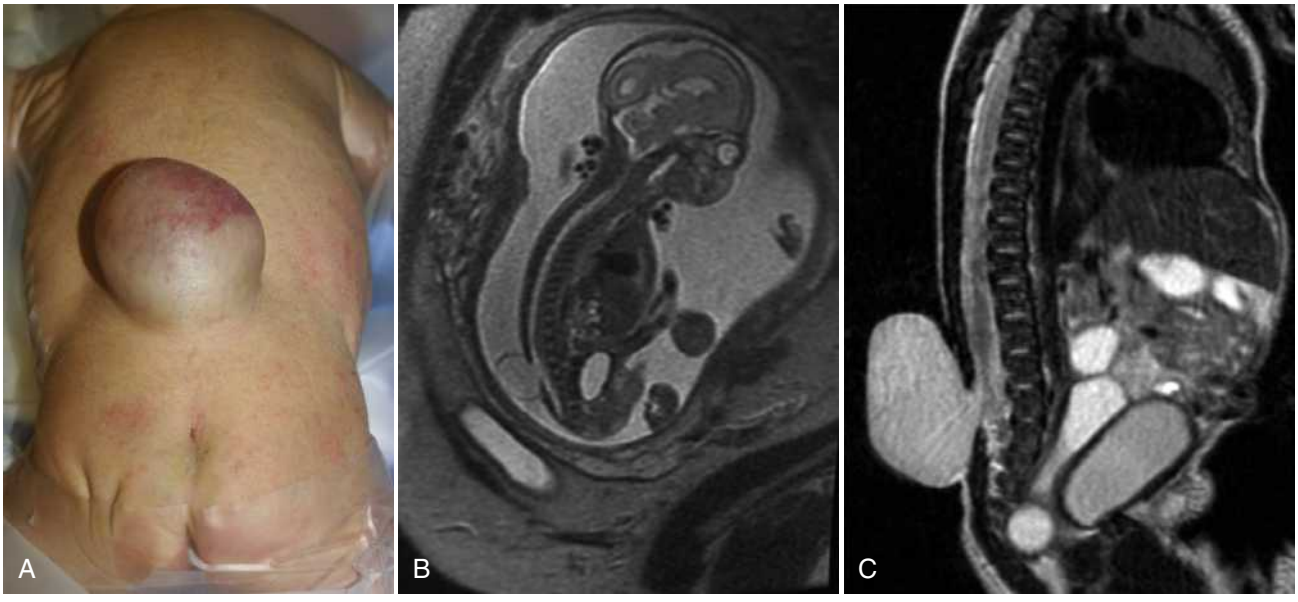

FIG. E1 Lumbar meningocele in a newborn. A, External appearance of the skin. **B,** Midline sagittal view from a fetal T2-weighted magnetic resonance image (MRI) study depicts a fluid-filled cystic lesion. Note homogeneous water signal within the lesion, suggesting the diagnosis of meningocele, rather than meningomyelocele. **C,** Midline sagittal T2-weighted image from the postnatal MRI showing the fluid-filled sac and the spinal cord within the spinal canal. (From Swaiman KF et al: *Swaiman's pediatric neurology, principles and practice,* ed 6, Philadelphia, 2017, Elsevier.)

TABLE E1 Prognosticating in Myelomeningocele

Motor Level Spinal Cord Segment	Critical Motor Function Present	Mobility: School Age	Range: Adult	Activity: Adolescent
T12	Totally paralyzed lower limbs	Standing brace, wheelchair	Wheelchair	Wheelchair, no ambulation
L1-L2	Hip flexor muscles	Crutches, braces, wheelchair	Wheelchair, household ambulation	Wheelchair, nonfunctional ambulation
L3-L4	Quadriceps muscles	Crutches, braces, household ambulation, wheelchair	Crutches, household ambulation, wheelchair	50% Wheelchair, household ambulation with crutches
L5	Medical hamstrings, anterior tibial muscles	Crutches, braces, community ambulation	Crutches, community ambulation	Community ambulation with crutches
S1	Lateral hamstring and peroneal muscles	Community ambulation	Community ambulation	Community ambulation 50% crutch or cane
S2-S3	Mild loss of intrinsic foot muscles possible	Normal	Normal	Limited endurance because of late foot deformities

From Braddon RL (ed): *Physical medicine & rehabilitation,* ed 4, Philadelphia, 2011, WB Saunders, Table 54.1, p. 1284.

PEARLS & CONSIDERATIONS

All mothers of children with neural tube defects should be instructed on nutritional supplementation with folate for future pregnancies.

COMMENTS

- Intrauterine repair of meningomyelocele decreases the incidence of hindbrain herniation and shunt-dependent hydrocephalus in infants, but increases the incidence of premature delivery and is associated with maternal and fetal risks.
- U.S. Public Health Service recommends 400 mg of folate intake per day for all women capable of becoming pregnant for primary prevention of neural tube defects.

Meniscal Tear

BASIC INFORMATION

DEFINITION

Damage or tear of semicircular cartilage located between the femur and tibia in the knee joint. Each knee joint contains two menisci (medial and lateral). Classically, injury results from forceful twisting or rotation of the knee.

SYNONYMS

Knee cartilage tear
Tear of semilunar or semicircular cartilage

ICD-10CM CODES

S83.202	(A,D,S) Bucket-handle tear of unspecified meniscus, current injury, unspecified knee
S83.209	(A,D,S) Unspecified tear of unspecified meniscus, current injury, unspecified knee
S83.219	(A,D,S) Bucket-handle tear of medial meniscus, current injury, unspecified knee
S83.229	(A,D,S) Peripheral tear of medial meniscus, current injury, unspecified knee
S83.239	(A,D,S) Complex tear of medial meniscus, current injury, unspecified knee
S83.259	(A,D,S) Bucket-handle tear of lateral meniscus, current injury, unspecified knee
S83.269	(A,D,S) Peripheral tear of lateral meniscus, current injury, unspecified knee
S83.279	(A,D,S) Complex tear of lateral meniscus, current injury, unspecified knee

A, Initial encounter; *D,* subsequent encounter; *S,* sequela.

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE:

- Estimated >200,000 cases per yr in the U.S.

PEAK INCIDENCE:

- Males: Peak incidence 21 to 30 yr.
- Females: Peak incidence 11 to 20 yr.
- In patients older than 65 yr, 60% of meniscal tears are degenerative.

PREVALENCE (IN U.S.):

- May be the most common knee injury.
- Estimated prevalence of acute meniscal tears: 61 cases per 100,000 persons.

PREDOMINANT AGE AND SEX

- Overall male:female incidence: Approximately 2.5 to 1.
- Rare in children younger than 10 yr.
- Degenerative tears are common in patients older than 65 yr.

RISK FACTORS: Trauma, age

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Key historical points:
  1. Mechanism of injury (e.g., twisting, squatting, or cutting maneuver on a weight-bearing knee)
  2. Pain (commonly intermittent and localized to the joint line)
  3. Mechanical complaints (clicking, popping, or painful locking of the joint on either flexion or extension of the knee)
  4. Swelling (often delayed, sometimes absent; degenerative tears may manifest with recurrent effusions)
- Physical examination findings suggestive of a potential meniscal injury include:
  1. Joint line tenderness
  2. Presence of knee effusion
  3. Impaired range of motion (locking of knee joint may occur with severely displaced tears)
- Several provocative examination maneuvers have been developed to aid in diagnosing ligamentous and meniscal injuries. Common stability tests include:
  1. **McMurray test:** Patient lies supine with the knee hyperflexed. The foot is grasped by examiner with one hand and the knee with the other. The examiner then flexes and extends the knee while simultaneously internally and externally rotating the tibia on the femur and providing slight varus and valgus stress. Positive test result is the presence of "clicking" palpable along the joint line or locking of the knee.
  2. **Apley grinding test:** With patient prone, knee is flexed 90 degrees, and the leg is internally and externally rotated with downward pressure applied to the heel. Presence of popping and/or pain localized to the joint line indicates a positive test. The pain should be relieved with distraction of the knee and rotation of the leg back to a neutral position.
  3. **Thessaly test:** Hold patient's outstretched hands while he or she stands flat-footed on one leg, internally and externally rotating three times with the knee flexed 20 degrees. Presence of pain or "clicking" indicates a positive test. Test first with the uninjured knee for comparison.
- Above-mentioned maneuvers are variably accurate, at best, when compared with magnetic resonance imaging (MRI) or arthroscopy findings.

ETIOLOGY

- May arise from a single traumatic event, a degenerative process, or a combination.
- Force required can be minimal, such as rising from a chair while turning.
- Intermittent locking of the knee results from a meniscal fragment blocking joint movement.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Patellofemoral pain syndrome
- Popliteal tendinitis
- Loose bodies
- Osteochondrotic lesions
- Tibial spine fractures
- Plica syndromes
- Inflammatory arthritis

WORKUP

- Rule out fracture or vascular injury.
- Identify potential infections and inflammatory conditions hidden by a history of minor trauma.

LABORATORY TESTS

None needed

IMAGING STUDIES

- MRI: Criterion standard for imaging meniscus pathology and associated intraarticular disorders. Fig. E1 illustrates a normal meniscus. Tears can be horizontal/oblique (Figs. E2 and E3), vertical (Figs. E4 and E5), bucket handle (Figs. E6 and E7), radial (Figs. E8 and E9), and parrot beak (Figs. E10 and E11).
- Arthroscopy: Perhaps the best tool for diagnosing meniscal tear. Both therapeutic and diagnostic and offers the option of immediate treatment of most meniscal disorders.
- Plain radiographs of the knee are not helpful in establishing diagnosis of meniscal tear.

TREATMENT

- Recommendations must take into consideration the patient's age, activity level, duration of symptoms, type of meniscus tear, and associated injuries, such as ligamentous pathology.

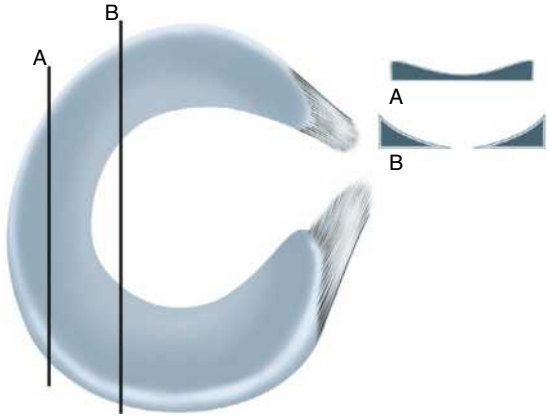

FIG. E1 Normal meniscus. This schematic shows the normal "bow tie" configuration at the periphery of the meniscus **(A)** and triangular configuration of the anterior and posterior horns of the menisci more centrally **(B)** on sagittal images. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Elsevier.)

- Trial of conservative treatment should be attempted in all but the most severe cases, such as a locked knee secondary to a displaced tear.
- Unfortunately, most tears do not heal without operative intervention.

NONPHARMACOLOGIC THERAPY

- Home physical therapy (PT) program: Goals are to minimize effusion, normalize gait and pain-free range of motion, prevent muscle atrophy, maintain proprioception, and maintain cardiovascular fitness.
- Ice, rest, and activity modification.
- Surgical intervention may be considered for patients with persistent symptoms that limit activity.
- Untreated tears may increase in size and may abrade articular cartilage, resulting in arthritis.
- Surgical options (arthroscopic or open) include the following:

1. Partial meniscectomy: Treatment of choice for tears in the avascular portion of the meniscus or complex tears that are not amenable to repair.
2. Meniscus repair: Recommended for tears located in the vascular region, those longer than 1 cm, root tears, those involving greater than 50% of the meniscal thickness, and tears that are unstable to arthroscopic probing.
3. Meniscus transplantation: A relatively new procedure for which specific indications and long-term results have not yet been clearly established.

ACUTE GENERAL Rx

Nonsteroidal antiinflammatory drugs

CHRONIC Rx

- Natural history of a short (<1 cm), vascular, longitudinal tear is often one of healing or resolution of symptoms with conservative treatment.
- Likewise, stable tears with minimal displacement, degenerative tears, or partial-thickness tears may become asymptomatic with nonoperative treatment.

DISPOSITION

Outpatient management

REFERRAL

- Referral to an orthopaedic surgeon is warranted if conservative treatment does not lead to resolution of symptoms.
- Urgent orthopaedic consultation is required for a knee that is locked and cannot be extended or flexed secondary to a displaced bucket handle meniscal tear.

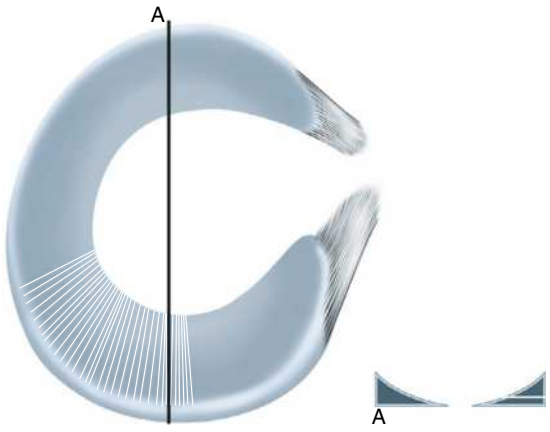

FIG. E2 Horizontal/oblique tear. This schematic shows the appearance of a horizontal meniscal tear *(A)* seen on a sagittal image through the meniscus. The tear can extend to the articular surfaces or the free apical edge of the meniscus. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Elsevier.)

PEARLS & CONSIDERATIONS

COMMENTS

- Meniscal tears commonly accompany ligamentous injuries, especially ACL tears.
- Most meniscal tears might not require surgery. A recent 2-yr follow-up study showed no benefit of partial meniscectomy compared to sham procedure in patients with knee pain and nontraumatic meniscal tears without osteoarthritis.[1]

PREVENTION

Avoiding high-impact maneuvers that are higher risk for meniscal tears

[1]Sihuonen R et al: Arthroscopic partial meniscectomy versus placebo surgery for a degenerative meniscus tear: a 2-year follow-up of the randomized controlled trial, *Ann Rheum Dis* 77:188, 2018.

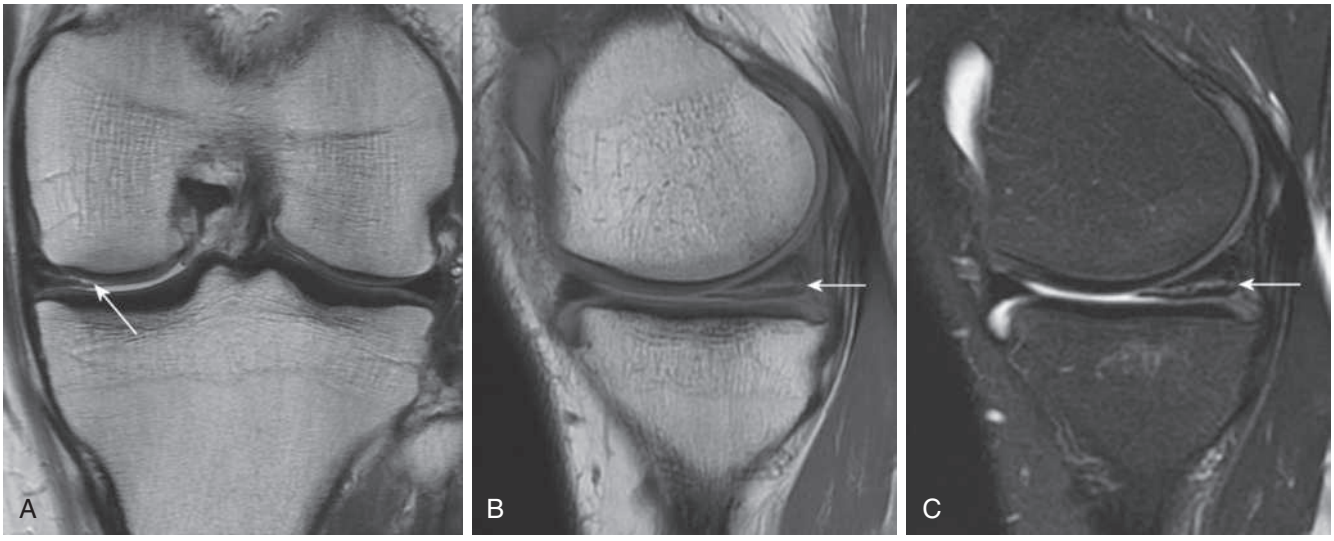

FIG. E3 Horizontal tear. Coronal and sagittal fast spin-echo, proton density-weighted (TR/TE 2200/15) **(A, B)** and sagittal T2-weighted, fat-suppressed, fast spin-echo (TR/TE 2800/63) **(C)** MR images through the knee. A medial meniscal tear is present *(arrows)* with extension to the free apical margin of the body and posterior horn of the meniscus. *MR,* Magnetic resonance; *TE,* echo time; *TR,* repetition time. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Elsevier.)

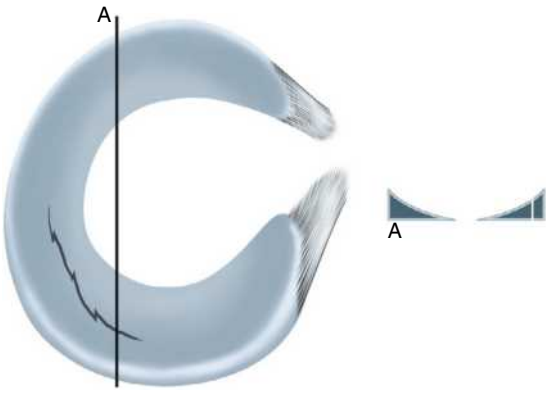

FIG. E4 Vertical tear. This schematic shows the appearance of a vertical meniscal tear *(A)* seen on a sagittal image through the meniscus. The tear can extend to both the superior and inferior articular surfaces of the meniscus. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Elsevier.)

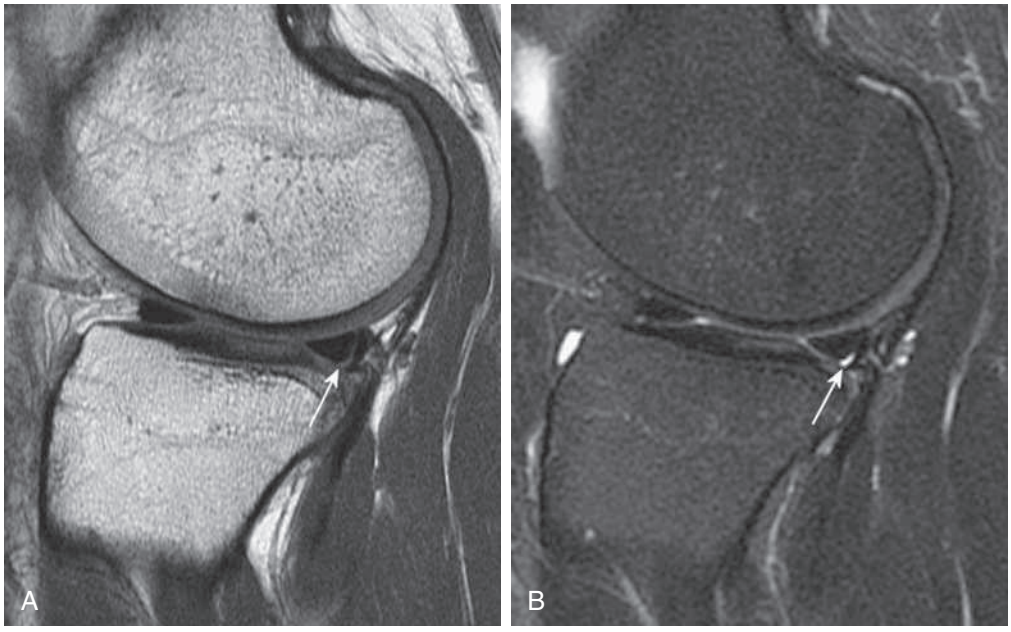

FIG. E5 Vertical tear. Sagittal fast spin-echo, proton density-weighted (TR/TE 2200/15) **(A)** and sagittal T2-weighted, fat-suppressed, fast spin-echo (TR/TE 2800/63) **(B)** images through the knee. A vertical tear is seen in the posterior horn of the lateral meniscus *(arrows). TE,* Echo time; *TR,* repetition time. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Elsevier.)

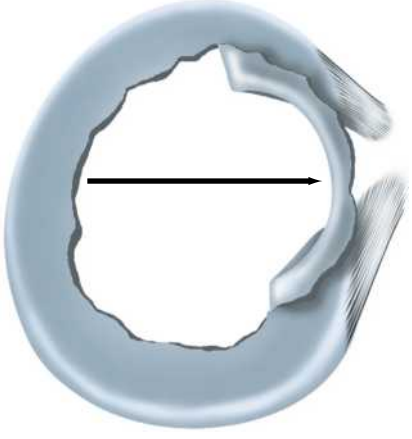

FIG. E6 Bucket handle tear. This schematic shows a centrally displaced fragment of meniscal tissue due to an extensive vertical longitudinal tear. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Elsevier.)

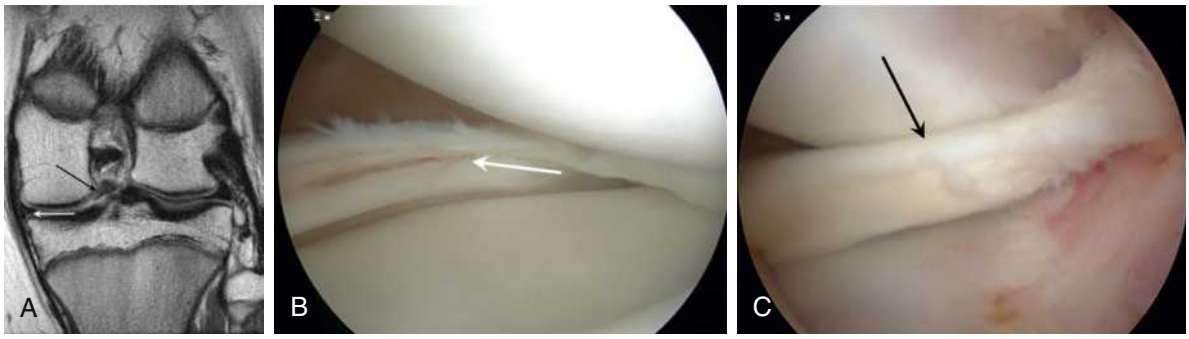

FIG. E7 Bucket handle tear with tear of the meniscal remnant and arthrographic correlation. A, Coronal fast spin-echo, proton density-weighted (TR/TE 2200/15) through the knee with a bucket handle tear and displaced meniscal tissue centrally in the intercondylar notch *(black arrow).* Oblique horizontal tear is in the remnant meniscal body *(white arrow).* **B,** Arthroscopic correlation demonstrating an oblique horizontal tear in the remnant meniscal body. **C,** Centrally displaced meniscal tissue. *TE,* Echo time; *TR,* repetition time. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Elsevier.)

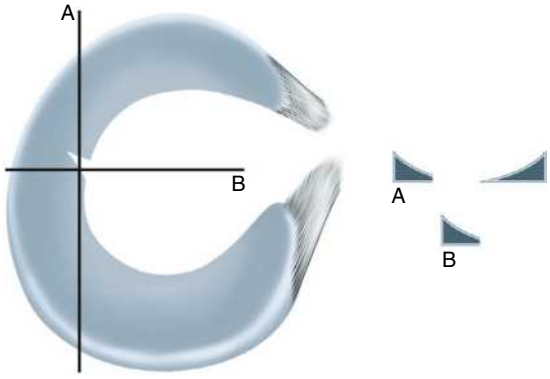

FIG. E8 Radial tear. This schematic shows a radial tear along the free edge of the meniscal body. This causes a blunted appearance on the sagittal **(A)** and coronal **(B)** images. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Elsevier.)

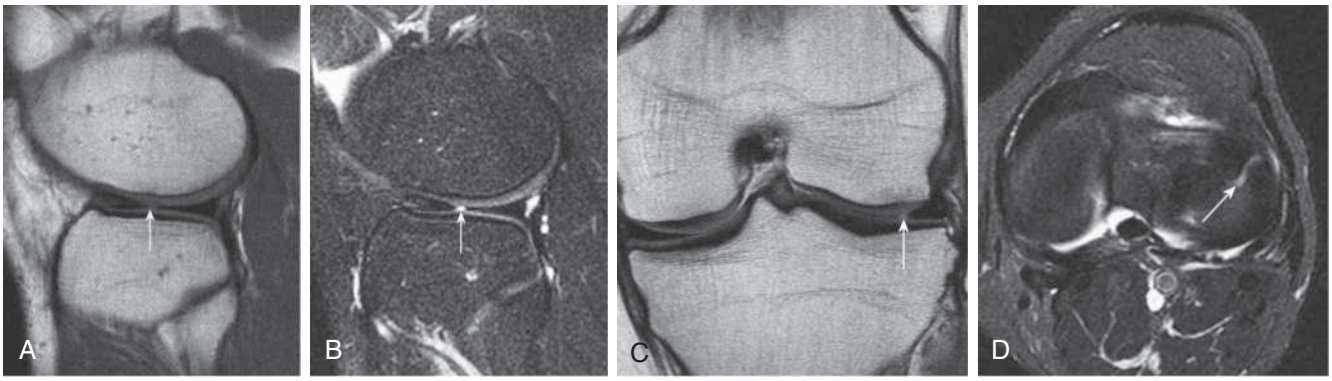

FIG. E9 Radial tear. Sagittal and coronal fast spin-echo, proton density-weighted (TR/TE 2200/15) **(A, C)** and sagittal and axial T2-weighted, fat-suppressed, fast spin-echo (2800/63) **(B, D)** MR images through the knee. A defect is seen in the normal bow tie configuration of the meniscus on the sagittal images, and there is a blunted appearance to the normal triangular configuration at the free apical margin of the meniscal body on the coronal image, consistent with a radial tear. This is confirmed on the axial image, which shows a radially oriented tear cleft through the body of the meniscus *(arrows). MR,* Magnetic resonance; *TE,* echo time; *TR,* repetition time. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Elsevier.)

FIG. E10 Parrot beak tear. This schematic shows a radial tear configuration along the free apical margin of the meniscal body with a small, contiguous portion that extends along the longitudinal orientation of the meniscus, giving the appearance of a parrot beak. (From Pope TL et al: *Musculoskeletal imaging,* ed 2, Philadelphia, 2015, Elsevier.)

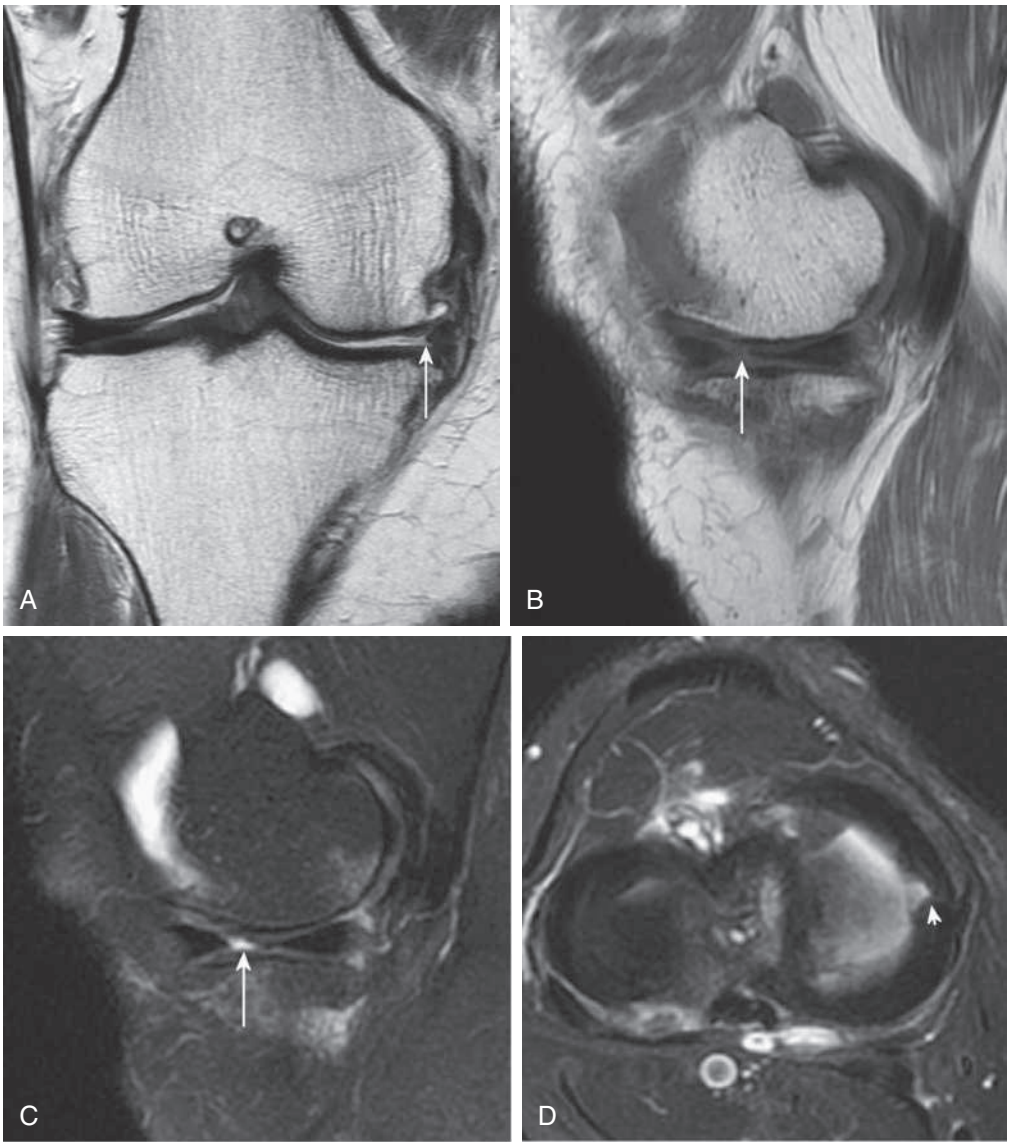

FIG. E11 Parrot beak tear. Coronal and sagittal fast spin-echo, proton density-weighted (TR/TE 2200/15) **(A, B)** and sagittal and axial T2-weighted, fat-suppressed, fast spin-echo (2800/63) **(C, D)** MR images through the knee. The coronal and sagittal images demonstrate a radial-type tear with blunting of the free apical margin of the meniscal body (*long arrow*, **A** through **C**). This also can be seen on the axial image, which has a small portion of the tear that begins to course along the longitudinal orientation of the meniscus, forming a parrot beak configuration (*short arrow*, **D**). *MR,* Magnetic resonance; *TE,* echo time; *TR,* repetition time. (From Pope TL et al: *Musculoskeletal imaging*, ed 2, Philadelphia, 2015, Elsevier.)

BASIC INFORMATION

DEFINITION

Menopause is the permanent cessation of menstrual periods for 1 yr after age 40 or permanent cessation of ovulation after lost ovarian activity without any other obvious pathologic or physiologic cause. It is the reproductive stage of life marked by waxing and waning estrogen levels followed by decreasing ovarian function. Primary ovarian insufficiency (previously also referred to as premature ovarian failure) and no menstrual periods may also occur because of depletion of ovarian follicles before the age of 40 yr.

SYNONYMS

Change of life
Climacteric ovarian failure

ICD-10CM CODES	
E28.310	Symptomatic premature menopause
E28.319	Asymptomatic premature menopause
N95.1	Menopausal and female climacteric states
N95.8	Other specified menopausal and perimenopausal disorders
Z78.0	Asymptomatic menopausal state

EPIDEMIOLOGY & DEMOGRAPHICS

- Average age of menopause in the U.S. is 51 yr.
- Age at which menopause occurs is primarily genetically determined.
- Smokers experience menopause an average of 1.5 yr earlier than nonsmokers.
- The menopausal transition, or perimenopause, begins on average 4 yr before the last menstrual period.
- Onset of perimenopause is usually in a woman's mid- to late-40s.
- Approximately 4000 women begin menopause each day.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

- Menopausal vasomotor symptoms: (VMS, hot flashes, flushes), night sweats, cardiovascular disease, coronary artery disease, atherosclerosis, headaches, tiredness, and lethargy; the median duration of hot flashes is 7.4 yr, but that the length of hot flashes was largely dictated by how early they began in the perimenopause
- Either complete cessation of menses or a period of irregular cycles and diminished or heavier bleeding
- Atrophic vaginitis, which can cause burning, itching, bleeding, dyspareunia
- Osteoporosis
- Osteopenia
- Psychological dysfunction:
  1. Anxiety
  2. Depression
  3. Insomnia
  4. Nervousness
  5. Irritability
  6. Inability to concentrate
- Sexual changes, decreased libido, dyspareunia
- Urinary incontinence

ETIOLOGY

- The most common etiology: Physiologic, caused by depleted granulosa and theca cells that fail to react to endogenous gonadotropins, producing less estrogen; decreased negative feedback in the hypothalamic pituitary access, increased follicle-stimulating hormone (FSH), and increased luteinizing hormone (LH), which leads to stromal cells that continue to produce androgens as a result of the LH stimulation
- Surgical castration
- Other factors that contribute to menopause can be family history of early menopause, cigarette smoking, blindness, abnormal chromosomal karyotype (Turner syndrome, gonadal dysgenesis), precocious puberty, and left-handedness

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Primary ovarian insufficiency
- Asherman syndrome
- Hypothalamic dysfunction
- Hypothyroidism
- Pituitary tumors
- Adrenal abnormalities
- Ovarian abnormalities
- Polycystic ovarian syndrome
- Pregnancy
- Ovarian neoplasm
- Tuberculosis of the endometrium

WORKUP

- Physical examination, height, weight, blood pressure, breast examination, and pelvic examination are needed.
- If the clinical picture is highly suggestive of menopause, reassurance or hormone replacement therapy such as estrogen can be prescribed to help with menopausal symptoms (after appropriate counseling). If all symptoms resolve, then a diagnosis essentially has been made. Before estrogen is prescribed, however, a complete history and physical examination are needed. If a patient has an estrogen-dependent malignancy, unexplained abnormal uterine bleeding, a history of thrombophlebitis, or acute liver disease, estrogen therapy is contraindicated.
- Progesterone challenge test: Medroxy progesterone 10 to 20 mg PO or progesterone 100 mg IM to induce withdrawal bleeding. If no withdrawal bleeding is obtained, a hypoestrogenic state is assumed to be present. This test is increasingly controversial, even if very commonly performed.
- Assess risk for coronary artery disease, osteoporosis, cigarette smoking, personal history, history of breast cancer, liver disease, active coagulation disorder, or any unexplained vaginal bleeding.

LABORATORY TESTS

- FSH, LH, and estrogen levels: Markedly elevated FSH and markedly depressed estrogen level constitute laboratory diagnosis of ovarian failure; LH only if polycystic ovarian disease is to be ruled out in a younger patient. It is not necessary to obtain an FSH if the patient fulfills the clinical criteria for menopause. Similarly, since estradiol levels vary during the menstrual cycle, estradiol levels are rarely necessary or informative.
- Anti-Müllerian hormone (produced by the granulosa cells) will demonstrate a decrease.
- TSH to rule out thyroid dysfunction and prolactin level if patient has symptoms of galactorrhea and if suspicion of pituitary adenoma exists.
- A general chemistry profile to check for any systemic diseases.
- Pap smear per standard guidelines, endometrial biopsy, or dilation and curettage in patients who have had irregular periods or intermenstrual or postmenopausal bleeding.
- Mammogram as recommended by American Congress of Obstetricians and Gynecologists for preventative care.

IMAGING STUDIES

- Per standard protocols, CT scan or MRI of sella if pituitary tumor is suspected
- Bone density studies if high-risk condition for osteoporosis exists
- Pelvic ultrasound to check endometrial stripe as determined by clinical history (i.e., in the setting of postmenopausal bleeding)

TREATMENT

NONPHARMACOLOGIC THERAPY

- A balanced diet: Low in fat, with total fat intake being <30% of calories; total calories sufficient to maintain body weight or produce weight loss if that is desired
- Avoidance of smoking and excessive alcohol or caffeine intake
- Exercise: Weight-bearing exercise for osteoporosis prevention
- Kegel exercises for strengthening the pelvic floor
- Adequate calcium intake: 1500 mg elemental calcium daily is necessary to maintain zero calcium balance in postmenopausal women
- Change in the ambient temperature (may ameliorate hot flashes and reduce night sweats)
- Vitamin E
- Avoidance of caffeine, alcohol, and spicy foods if they trigger hot flashes
- Vaginal lubricants to help with the dyspareunia attributable to vaginal dryness (e.g., Replens, K-Y Jelly, or Gyne-Moistrin cream)

ACUTE GENERAL Rx

Vasomotor symptoms are best managed with systemic hormone therapy given in the lowest dose and for the shortest period possible. Estrogen replacement in symptomatic patients can be administered in a variety of forms, including oral estrogen and transdermal estrogen patch. The lowest effective dose should be prescribed.

- Examples of oral estrogen include:
  1. Conjugated estrogens: Start with 0.3 mg daily and increase to 1.25 mg daily depending on symptoms.
  2. Estradiol: Start with 0.5 mg daily and increase up to 2 mg daily.
  3. Esterified estrogens: Start with 0.3 to 1.25 mg daily.
  4. Estropipate: Start with 0.75 to 3.0 mg daily.
  5. Esterified estrogen/testosterone combination: Give 1.25 mg and methyltestosterone 2.5 mg (Estratest) and esterified estrogen 0.625 mg and methyltestosterone 1.25 mg (Estratest HS [half-strength]). May improve sexual enjoyment and libido.
- If the patient has had a hysterectomy for benign disease, estrogen alone is sufficient. In patients who have an intact uterus, progestin is critical to prevent endometrial hyperplasia associated with unopposed estrogen, which is protective against endometrial cancer. Progestins can be prescribed as continual daily dose or cyclic fashion. Most commonly prescribed progestins include medroxyprogesterone acetate 2.5 mg, 5 mg, and 10 mg; Prometrium 100 mg, 200 mg, and 400 mg; and Aygestin 5 mg. Continuous hormone replacement therapy is preferred because after time the patient should be amenorrhoeic. Patients should be counseled that they may experience some irregular spotting for the first 6 to 9 mo after starting hormone replacement therapy. Cyclic therapy will cause withdrawal bleeding.
- Combination oral preparations Femhrt, Prefest, Prempro, Activella, Premphase are commonly used. However, the U.S. Preventive Services Task Force recommends against the use of combined estrogen and progestin for the prevention of chronic conditions such as cardiovascular disease in postmenopausal women.
- The combination of conjugated estrogen and bazedoxifene is approved for the treatment of moderate to severe vasomotor symptoms associated with menopause and also for prevention of postmenopausal osteoporosis in women with an intact uterus.
- Transdermal patches can be either estradiol (Estraderm, Vivelle, FemPatch) 0.025 to 0.1 mg applied twice weekly or Climara 0.025 to 0.1 mg used once a wk. With these preparations, progesterone should be used in a similar fashion. Apply CombiPatch twice weekly (combination estrogen and progesterone) or Climara Pro once per wk (one patch).
- Vaginal creams can be used; these should be reserved for local therapy of atrophic vaginitis. Minimal systemic absorption does occur; however, blood levels are unpredictable. Usual dose 0.5 to 2 g intravaginally daily, cyclically 3 wk on 1 wk off. When symptoms improve, once to twice weekly is adequate maintenance.
- Vagifem estradiol vaginal tablets. Initial dosage: One Vagifem tablet, inserted vaginally, daily for 2 wk. Maintenance dose: One Vagifem tablet, inserted vaginally, twice weekly.
- Femring vaginal ring delivering the equivalent of 0.5 mg/day inserted every 3 mo or Estring 0.0075 mg/day.
- EstroGel 0.06% (estradiol gel) One Pump (1.25 g/day) applied to one arm from wrist to shoulder.
- The FDA contraindications to menopause hormone therapy include the following diseases and disorders: Active liver disease; current, past, or suspected breast cancer; active or recent anterior thromboembolic disease (angina, myocardial infarction); known or suspected estrogen-sensitive malignant conditions; known hypersensitivity to the active substance of the therapy or to any of the excipients; porphyria cutanea tarda; previous idiopathic or current venous thromboembolism; undiagnosed genital bleeding; untreated hypertension; untreated endometrial hyperplasia.
- For women in whom estrogen is contraindicated or for those who do not wish to take estrogen, the following regimens can be used:
  1. Serotonin reuptake inhibitors, especially in women with menopausal mood disorders
  2. Depo-Provera 150 mg IM every mo (may be helpful in alleviating hot flashes)
  3. Clonidine 0.05 to 0.15 mg PO daily (questionable efficacy) or transdermal clonidine patch
  4. Bellergal-S (questionable efficacy)
- Tibolone significantly improves vasomotor symptoms, libido, and vaginal lubrication. Not available in the U.S.

CHRONIC Rx

Hormone replacement therapy should be used only for the short term unless benefits outweigh the risks of long-term use. As a result of the results of the Women's Health Initiative (WHI), the FDA has instituted a "black box" warning on postmenopausal hormone replacement products suggesting that the lowest dose should be used for the shortest period of time. This necessitates a considered counseling session with patients contemplating hormone replacement prior to the initiation of therapy and then on a periodic basis after that, usually at least on a yearly basis.

DISPOSITION

If treated, the patient should have resolution of her symptoms and reduced incidence of osteoporosis. Lifelong medical supervision is necessary to monitor adequacy of treatment and prevention of complications. This should include regular Pap smears in accordance with American Society for Colposcopy and Cervical Pathology (ASCCP) guidelines until the age of 65, pelvic examinations, breast examinations, mammography, and endometrial sampling of any type of abnormal bleeding. If untreated, the vasomotor symptoms will eventually dissipate; however, this may take several years in a small percentage of women. Some women who are in their 80s have experienced hot flashes. Urogenital atrophy will continue to worsen. Osteoporosis and coronary artery disease risks will increase with every passing yr.

REFERRAL

Most menopausal women are managed by their gynecologists. However, this condition can be managed adequately by the patient's primary care physician who has an interest in treating menopausal women.

PEARLS & CONSIDERATIONS

COMMENTS

- Short-term risks of hormone replacement therapy (HT) include an eighteenfold increased rise for cholecystitis, three-and-a-halffold risk of a thrombo-cardiac event in the first yr, and possible increased risk of stroke and myocardial infarction.
- Results of the WHI study found that for every 10,000 women taking HT (combination of both estrogen and progesterone) for 1 yr (10,000 person-yr), seven more would have coronary events, eight would have more strokes, eight would have more pulmonary emboli, and eight would have earlier breast cancer than would 10,000 women taking placebo. Benefits of HT were six fewer cases of colorectal cancer and five fewer hip fractures per 10,000 women.
- HT should not be initiated or continued for the primary or secondary prevention of coronary heart disease.
- Estrogen-replacement therapy should only be prescribed for patients with sufficient menopausal symptoms that impact the patient's quality of life.
- Interestingly, women who start hormone therapy early in menopause may have cardiac and other benefits. A recent trial showed that oral estradiol therapy was associated with less progression of subclinical atherosclerosis (measured as change in carotid-artery intima media thickness [CIMT]) than with placebo when therapy was initiated within 6 yr after menopause but not when it was initiated 10 or more yr after menopause. Estradiol had no significant effect on cardiac CT measures of atherosclerosis in either postmenopause stratum.[1]

Meralgia Paresthetica

BASIC INFORMATION

DEFINITION

Meralgia paresthetica is a condition that presents with pain and/or dysesthesia in the anterolateral thigh due to compression of the lateral femoral cutaneous nerve.

SYNONYMS

Lateral femoral cutaneous nerve entrapment
Bernhardt-Roth syndrome
Skinny pants syndrome: Named due to a rise in teenagers wearing skin-tight pants

ICD-10CM CODE
G57.1 Meralgia paresthetica

EPIDEMIOLOGY & DEMOGRAPHICS

INCIDENCE: The incidence rate for males and females is similar, and it is one of the most common mononeuropathies of the lower limb.
PEAK INCIDENCE: The mean age at diagnosis is 50 yr old.
RISK FACTORS: Obesity, diabetes mellitus, and older age are the most commonly associated conditions. Other risk factors include large abdomens, tight belts and garments around the waist, pregnancy, and scar tissue near the inguinal ligament. During surgery, iatrogenic injury or compression due to improper positioning is also an important cause of meralgia paresthetica. Motor vehicle accidents with seat belt injury are a less common but recognized cause. Long periods of leg exercise that increases tension on the inguinal ligament, such as from long distance biking or walking for an extensive period of time, may also cause pressure on the nerve. Leg-length discrepancy can also cause hip hyperextension, leading to symptoms. Alternatively, weight loss or aging may remove protective overlying fat layers so the nerve can squeeze against underwear, belts, or other clothing. Rare risk factors include ascites, endometriosis, and pelvic masses (neoplasms, hemorrhages, or abscesses), which can cause compression of the nerve.

PHYSICAL FINDINGS & CLINICAL PRESENTATION

The patient can have numbness and tingling, burning pain, or decreased sensation over the region of the outer upper thigh, which usually presents in a gradual fashion. Sometimes the patient will rub the affected area when discussing the discomfort. There is no motor involvement, as the lateral femoral cutaneous nerve only has sensory fibers. Change in patient position may abate the pain, with walking or standing often aggravating symptoms. However, if the cause is extrinsic compression, such as from a tight belt, sitting may exacerbate symptoms. Pain spreading across the buttocks or aching in the groin area can sometimes be present. Pain may radiate into the rib cage, groin, thigh, and knee. Often the affected region is more sensitive to light touch than to firm pressure. Hypersensitivity to heat can be present. Usually the symptoms are unilateral but can be bilateral in up to 20% of cases. Deep palpation below the anterior superior iliac spine (pelvic compression testing) can often reproduce symptoms.

ETIOLOGY

Meralgia paresthetica mainly results from entrapment of the lateral femoral cutaneous nerve (Fig. E1) as it passes under the inguinal ligament (Fig. E2). However, it can also be compressed within the lumbosacral plexus, abdominal cavity, or in the subcutaneous tissue of the thigh.

DIAGNOSIS

The diagnosis is based mainly on the unique description of pain and the typical location; the sensory abnormalities present on exam in the affected area without neurologic abnormalities on the lower half of the affected leg. Loss of sensation often can be clearly demarcated over the anterior thigh.

While the diagnosis should largely be a clinical one, studies have shown the success for ultrasound-guided diagnosis which reveals a hypoechoic and swollen lateral femoral cutaneous nerve.

DIFFERENTIAL DIAGNOSIS

Lumbar radiculopathy, vasculitic neuropathy

WORKUP

Usually the diagnosis requires no testing other than a thorough neurologic examination. The entire lower extremity should be examined. Light touch and pinprick examination are usually abnormal in an oval-shaped area on the anterolateral thigh. There should be no abnormality in the straight leg test, and there should be no findings suggesting hip, back, or sacroiliac joint involvement. Motor strength and deep tendon reflexes should be normal. On occasion, precise diagnosis may require an abdominal and/or pelvic examination to exclude problems in those areas.

IMAGING & OTHER STUDIES
